Center—Resta with Aitken on his heels leads the field
Bottom—The famous trio, Burman, Anderson and Rooney

tion back to the days of Rome where it was thumbs down for he who failed in battle.

Not an accident marred the day, although the management had provided surgeons and nurses for emergency.

Stutz Pit Signals Big Factor in Victory

All through the day the pits presented a busy scene. When not actually engaged in work upon the cars the attendants were signaling positions and instructions. It is not too much to say that a factor in the victory of the Stutz cars was the level-headed guidance from the pit coupled with the rigid obedience to these signals on the part of the drivers. Tire changes were made in 30 seconds and under. Gasoline was hurled into the tanks in marvelously short time but oftentimes with great wastage as the attendants in their excitement neglected the fact that the mouth of a funnel is only so large even if it is big enough to go over a man's head.

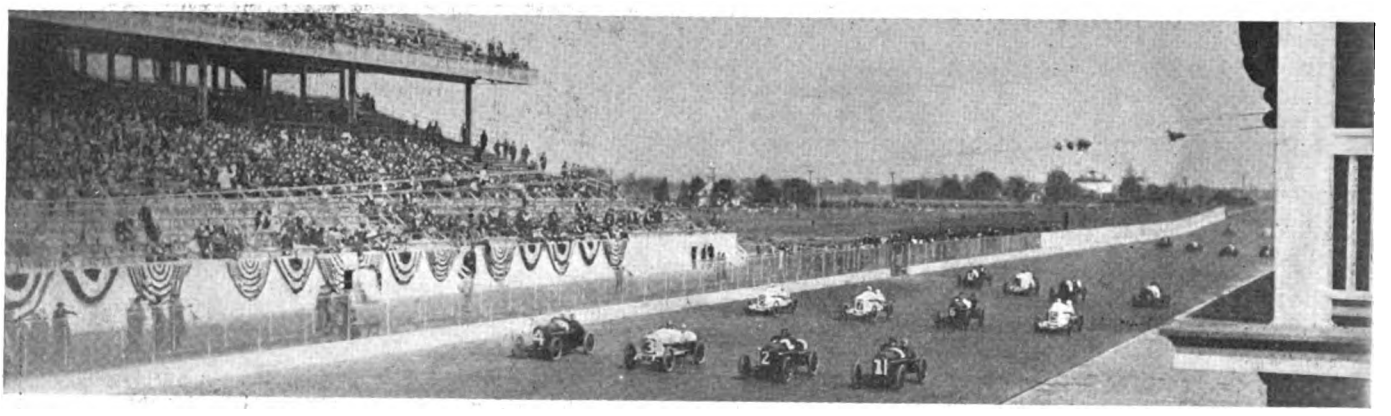
Winner Stopped Once

Anderson stopped but once to take on gasoline. Rooney in the second Stutz stopped once for gasoline and once again to change a right rear tire. O'Donnell's Duesenberg, which finished third, made one stop for gasoline and oil. Alley's Ogren stopped once for the same reason and Henderson, did likewise, with an additional pause for new plugs.

Mechanical troubles bothered the rest who finished, but a prominent fact is that of the eight cars which took prize money, only two changed tires, and these but one apiece. They were Rooney's Stutz and Limberg's Delage.

At 4 o'clock the race was over, having lasted 4 hr. from the time of start. After Anderson had flashed across the line the great crowd started to dwindle rapidly and as they slowly filed from the stands to the awaiting cars and trains the mingled comments arose in a murmur which could be heard throughout the great enclosure. Few regretted having seen the wonderful spectacle and the comments were mostly of awe-struck amazement at the fearful speed attained with the safety which was brought strongly to the fore by the lack of the slightest accident. Practically 103 m.p.h. average had been made for a distance of 350 miles. At this rate of speed it would take but 30 hr. to cross the great continent of America. It would take 10 days to encircle the globe at the equator.

At the end of the first 20 miles there were but eighteen cars of the twenty left in the race. Ralph Mulford had been forced to withdraw his Peugeot on account of a broken connecting rod and Barney Oldfield, with a broken piston, connecting rod and crankcase, also was out of the race. At this



Crossing the line for the first time on the 350-mile grind, showing how evenly the cars maintained their positions on the paced lap

time Resta's flying Peugeot was holding the lead, closely followed by Aitken in his Peugeot and Rooney's Stutz. Immediately behind with not a foot separating the two cars was Gil Anderson in the Stutz, which finally won the race. Resta was setting a heart-rending pace. He was clocked for the twenty-second lap in 65 sec. about 110 m.p.h., the fastest lap of the day. His speed for mile after mile averaged better than 107 m.p.h. This pace soon told on his tires and at the end of the twenty-ninth lap he was forced to make a change on his right rear. This delayed him but a few seconds but enough to lose the lead which was eagerly snatched by Gil Anderson; and the white Stutz racer now became the pacemaker. At 60 miles Anderson was leading with Rooney second and Resta, gaining a few yards on every stretch, third.

When 80 miles was reached Anderson had averaged 103.97 m.p.h. with Rooney still second, and Resta, making laps at 109 m.p.h., third. At 60 miles Ed Pullen's Maxwell and Earl Cooper's Stutz had been eliminated and at 80 miles Howard Wilcox's Peugeot felt the strain of the sustained pace and could not start again after coming to a stop on the north curve. Between the eightieth and one-hundredth miles no eliminations were made, but at 100 miles Resta was again in the lead, having caught the Stutz at 84 miles and shortly after Rooney halted for a tire change. Resta had passed the 100-mile mark in 57 min. and 26 sec., which exceeded the recent record on the Chicago track by nearly a minute and a half.

Peugeot Broke Rod

Just after rounding the turn on the 104th mile Resta's Peugeot began to slacken its pace. A connecting rod had failed and the car was out. It had to be pushed to the pits and the Stutz team had lost their most formidable antagonist. Close behind Resta at the 100th mile were Rooney, Anderson, Burman and Rickenbacker. Rickenbacker had not much farther to go, however, as at the 108th mile he also broke a connecting rod putting his Maxwell among the list of those who had tried but failed. With Resta eliminated, Aitken, who had been delayed at the start, by tire troubles, which persisted to such an extent that he had to make four changes in less than three-quarters of an hour, began to become an important factor in the race. Anderson led at the 120th mile, having covered the distance in 1 hr., 9 min. and 32 sec. at the rate of 103.52 m.p.h. At the 140th mile Anderson was still the leader but Aitkin was crawling up, being less than a minute behind. Burman's Peugeot was 23 sec. behind this, and Rooney 9 sec. back of Burman.

Near the 160-mile mark Vail, who drove the Mulford Special, was compelled to give way to a relief driver due to the fact that he was partially overcome by the fumes of burning castor oil. George Theobold took his place and was the only relief driver used in the race. At 156 miles LeCain had to quit the race on account of a broken clutch collar on the Pugh Special.

All this time Aitken was slowly gaining on Anderson until at the 160-mile mark the latter only led by 29 sec. Rooney followed third and Burman fourth just 2 sec. apart. The race had settled down to a four-sided affair with the two Stutzes against the two Peugeots of Aitken and Burman.

At the 186th mile Aitken flashed into the lead and once more those who were hoping for America to win began to lose heart. The Peugeot had shown superior speed to the Stutz but there was still 65 miles to go and that last 60 miles was a matter of endurance. Anderson, at the 186th mile, made his only stop of the day to take on gasoline. Aitken took advantage of the time to increase his lead by more than half a lap and at the 200-mile mark he led by close to a minute, Rooney taking and leading Burman with DePalma fifth. At this time O'Donnell was sixth, Henderson seventh, with the remaining cars trailing behind. But it was not for long that DePalma remained a factor in the race. At 210 miles a broken ball bearing drove him out, narrowing the field to ten.

By this time Aitken had gotten so far in the lead that it looked as if Burman's Peugeot and the two Stutz cars were to struggle for second place. It was a close fight and waves of excitement swept over the crowd. Only a few seconds separated them at any instant. In the meanwhile Aitken made a stop for gasoline which he managed to take on in 30 sec., but got away again so fast that this did not cost him his lead. Only a few minutes later, when he had traveled 240 miles a cracked cylinder ended his chances of winning the race and entirely altered the prospective leadership.

The fight was now between Burman and the two Stutzes. Rooney took the lead at 260 miles, a few hundredths of a second in advance and so close was it that the timing instrument clocked all three cars at 152 min. and 14 sec., although at this time Rooney led with Burman second and Anderson third with the speed 102.46 m.p.h up to that time. Here the leaders saw that the speed must be increased, if anything, for a win and, wheel to wheel, they tore around the track until 12 miles further on Rooney and Burman both stopped for gasoline. The stop took longer than it should have for Burman lost nearly a lap and a half to Anderson. Rooney also went ahead and with 70 miles still to go Anderson led with Rooney second and Burman third, the leader being 2 min. ahead of Burman.

Burman Made Race

From this point on Anderson held his lead with Rooney and Burman fighting for second place until 340 miles. Then came Burman's breakdown and the veteran, after his magnificent driving for 3½ hr., was compelled to abandon the race. Never did a man drive a more courageous race in vain. Never did a speedway crowd owe more to an unrewarded driver, for Burman made the race but won no prize. Had it not been for his determination 100 m.p.h. average need never have been reached.

Leaders Make Few Stops at Pits

One Tire Change of Five American Cars Which Finished—Broken Connecting-Rods and Spark Plug Troubles Prevalent—Average 5 Miles per Gallon of Fuel—Water Connections Leaked

IN the final analysis the Astor cup race was a struggle of endurance. The stamina of steel and other materials was tested to the utmost and that the stresses on the vital parts of the cars were always close to the ultimate was shown by the fact that from an original field of twenty but eight cars were running when the race was called off.

All the thrills and triumphs took place on the board track where the speeding cars forced the pace higher than ever before in a race of this character. At the pits the activities were not as spectacular but even more deeply filled with meaning as to the hopes and fears of the struggling pilots.

Six Cars Finished

Only six cars finished the 350 miles and two were running when the race was brought to a close. And of the six that finished, the first five were American cars which showed their endurance to such a degree that it need never be said again that America cannot produce cars at least equal to those of Europe. These five cars all were forced at some time during the race to come to the pits; but of the five three only made one stop each for fuel and oil. The other two made one additional stop each, the second Stutz to change a right rear tire and the Duesenberg, which finished fifth, made a change of plugs. Thus the total stops for the first five cars were but seven.

Limberg's Delage which finished sixth, and was the only foreign car to go the distance, stopped three times, making a change of a tire, taking on fuel and water besides making ignition and carbureter adjustment. The two other cars which remained in the running until flagged off the course were Haibe's Sebring and the Mulford Special. The first of these made seven stops and the other five stops.

Early in the race the remarkable pace set by the Peugeot team began to tell upon the striving cars which tried to follow their lead. Before the race was ½ hr. old eight cars had limped into the pits for various repairs. The race endured 4 hr. In the second half hour ten stops were made; in the third half hour period, five; in the fourth, five; in the fifth, eight; in the sixth, nine; in the seventh, four, and eighth, two.

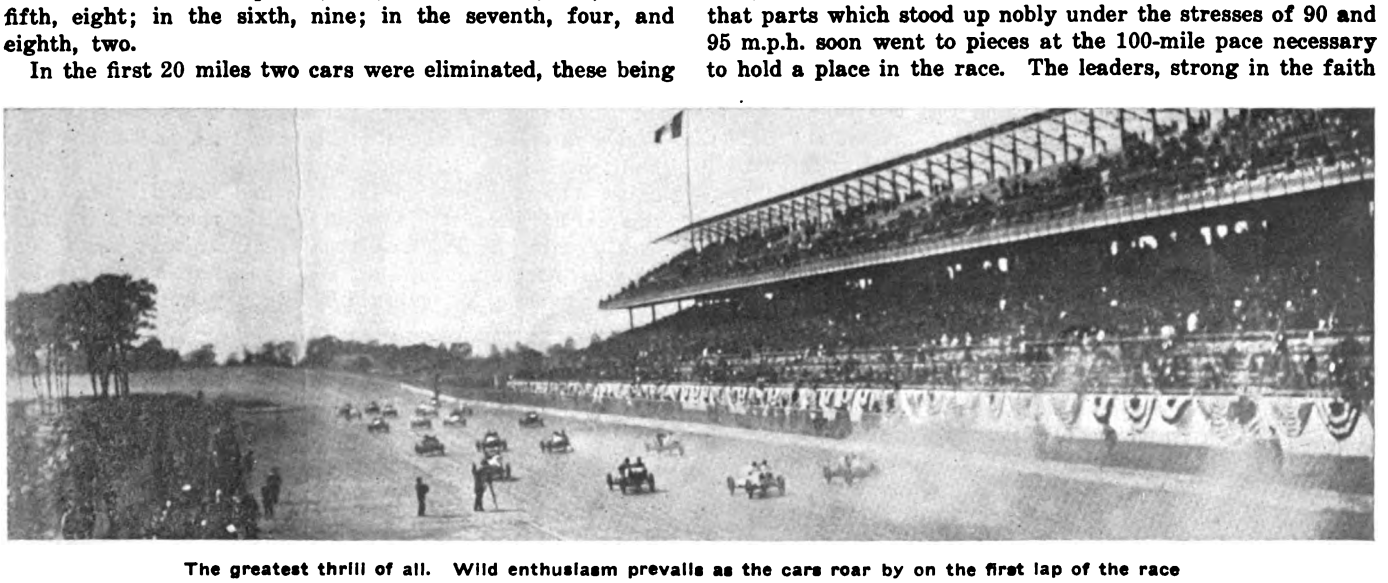
In the first 20 miles two cars were eliminated, these being Mulford's Peugeot and Oldfield's Delage. Between 40 and 50 miles two others went out, Cooper's Stutz and Pullen's Maxwell. Between 60 and 80 miles Wilcox's Peugeot dropped. The next to fall by the wayside were between 100 and 120 miles when Resta's Peugeot, the pacemaker to that time, and Rickenbacher's Maxwell broke down. The next elimination was Lecain's Pugh Special at 156 miles, then De Palma's Stutz at 210 miles, Aitken's Peugeot at 240 miles, Houk's Duesenberg at 254 and finally Burman's Peugeot with only 4 miles to go.

The greatest number of stops was for the replenishment of fuel tanks necessary for every one. On the average the tank capacities of the cars was about 40 gal. and on this amount they ran for about 200 miles, the fuel consumption average being quite close to 5 miles per gallon. The stops for gasoline were fourteen in all. Tires and oil were next in order of importance, ten stops being made for each, although oftentimes oil and gasoline were replenished at the same time that tires were changed. Tire troubles started early. Aitken's Peugeot, although afterwards in the lead and the pacemaker of the race, had to make four changes in the first 45 min. Before he had been on his way 20 min. he had to make his first change and another one 4 min. later.

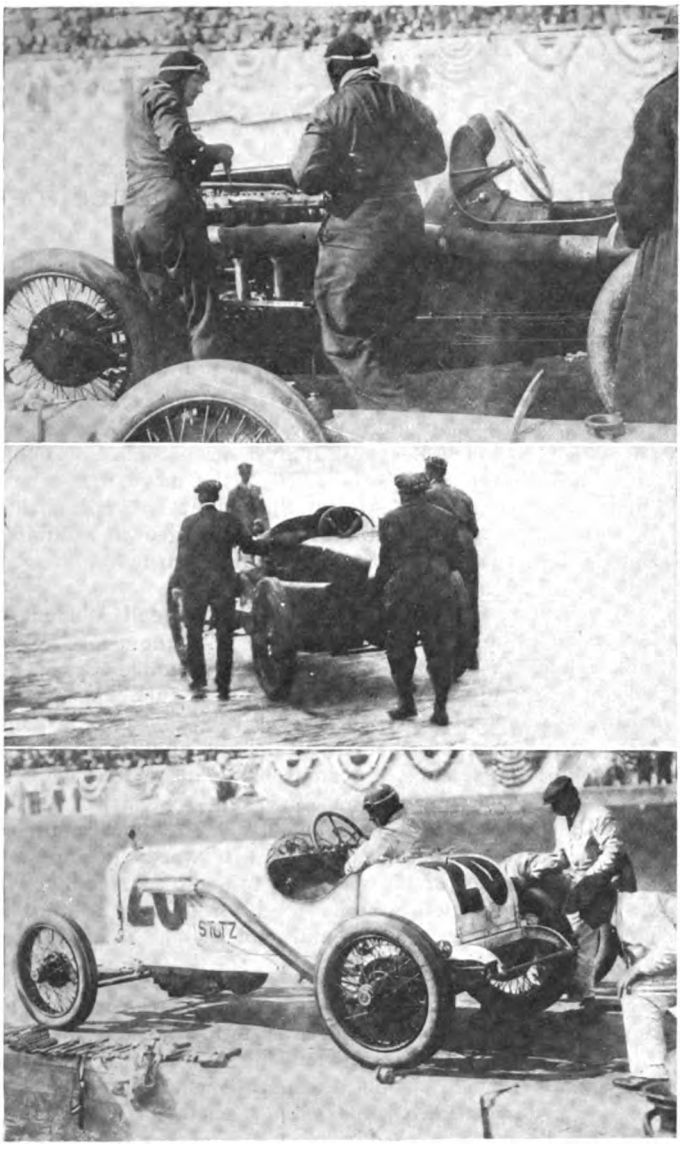
Mechanical Troubles Early

Mechanical troubles also started early in the race. The stops for spark plugs had a greater total than any other in this classification, seven cars pausing at the pits for their renewal. Carbureter troubles caused five interruptions; water systems four; valves and valve mechanisms three; connecting-rods four, and bearings two. Judging from the results during the race it almost looked as if connecting-rods defeated the Peugeot team, for three of the five had to abandon the race because these had broken.

Stops for such important reasons as breaks in the valve mechanism, connecting-rods and bearings were practically always fatal and resulted in withdrawal of the car from the race, and as time went on it became more and more evident that parts which stood up nobly under the stresses of 90 and 95 m.p.h. soon went to pieces at the 100-mile pace necessary to hold a place in the race. The leaders, strong in the faith



The greatest thrill of all. Wild enthusiasm prevails as the cars roar by on the first lap of the race



Studies of effort and of resignation. Top—Wilcox changes plugs. Center—Bringing in Resta's vanquished car. Lower—De Palma takes a new right rear tire as the other cars roar by

of the stamina of their cars immediately adopted the tactics of running the weaker competitors to death, and one by one those who had asked more than steel could supply were forced to crawl to the pits with parts broken that could not be repaired. Although attaining an average speed higher than any had anticipated, Gil Anderson did not have to come to the pits once for a tire replacement. His only stop was for gasoline. His team mate, who was less than a minute behind had stopped but once for tires and at the time of making his change, as much gasoline as could be thrown into the tank during the rapid change of wheels, was supplied. The tire change, however, was so rapid, that more gasoline was splashed on the concrete pit pavement than into the tank.

Six out of the eight who finished did not change a wheel from one end of the race to the other; in fact of the twenty who started but ten tire changes were made and among the eight who finished the total tire changes were two. Tom Rooney changed a right rear on his Stutz when the race was just an hour old, and Limberg changed a right front on his Delage half an hour after first crossing the line.

Making a study of the tire changes it is interesting to note that of the ten tires changed, nine were on the right side, the only left was the rear on Haupt's Duesenberg which was changed at the same time as the right rear because the pit attendants thought it looked worn. The tires at the end of the race did not seem to have traveled the 350 miles at such a speed and it was a noteworthy fact that most of the failures were not due to wear but rather to the ripping off of the tread. The only car equipped with fabric tires, that is Tom Alley's Ogren which had Nassaus, went through the race without a change.

After Oldfield's Delage and Mulford's Peugeot had been eliminated before 20 miles had been traveled, Wilcox brought his Peugeot to the pits for water and a right tire. The overheating was the first sign of the trouble which caused him later to drop out of the race. Fifteen minutes after his first stop he had to make another to take on more water and this time to change his plugs which were so hot that the points were fused practically together. Six minutes later a loose magneto wire, and irregular firing made him stop again, after which he was eliminated automatically by pushing his car which had developed engine trouble of such a serious nature that he could no longer run.

Aitken Had Tire Trouble

Aitken's tire troubles developed soon after the race started. A right front was changed after he had been on his way 19 min. Four minutes later a right rear, then a 16-min. interval and another right front, and 15 min. later another right rear. From this time on he suffered no more tire trouble, but later in the race, when he had held the lead for many a long mile, a broken valve and a cracked cylinder forced him to come to the pits. When water was put in the radiator it poured out the exhaust pipe showing that his trouble was too serious to resume the race.

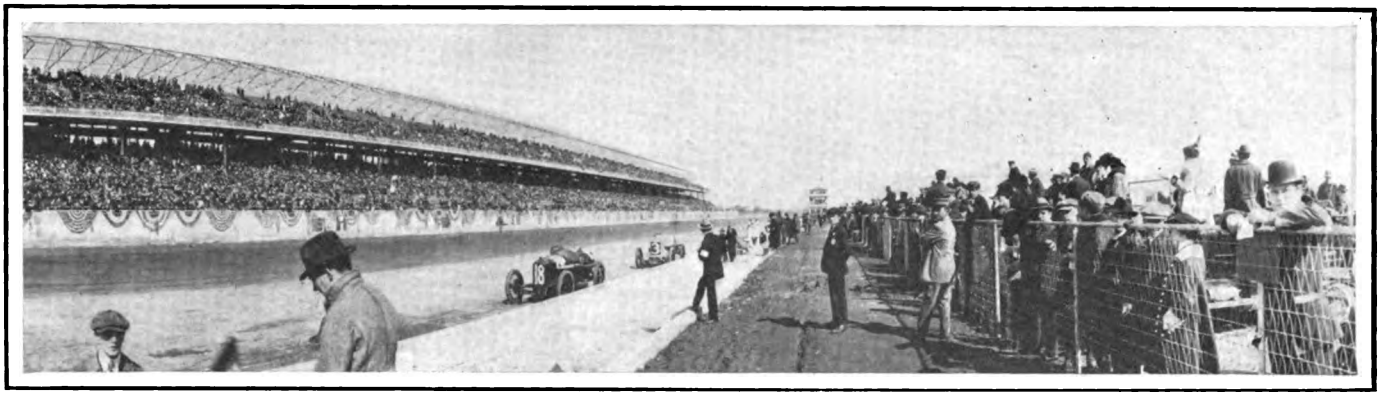
Spark-plug troubles which occurred frequently during the race showed that many of the drivers were either oiling so lavishly that the plugs had become sooted or the design of the cylinder casting was such that the heat was not carried rapidly enough away from the plugs. This bothered Haibe in his Sebring throughout the race. After traveling but 20 min. he stopped and renewed two plugs. Not 15 min. after this his water connections developed a leak and drenched his magneto. A half hour later he had the same trouble and then after another half hour he stopped for two new plugs and shortly after for three more and some oil. He took on plugs and oil again when he had been traveling for 2 hr. and changed two others just before finishing seventh.

A stop for change of plugs was made by Henderson in the Duesenberg not long after he had traveled three-fourths the distance. This was his second stop as when he had just about reached the half-way mark he took on gasoline and oil. Limberg in his Delage changed all his spark-plugs while taking on gasoline and making a carbureter adjustment just after Henderson in his Duesenberg had changed his plugs. The Limberg-Delage was one of the two who finished with tire changes, Tom Rooney, in his Stutz, being the other.

Ira Vail in the Mulford Special went through the greater part of the race with a trouble which threatened at any moment to become serious. This was a cracked exhaust sustained after he had been on his way 1 hr. and 40 min., and had traveled just half the 350 miles. He had a cracked exhaust manifold between the first and second cylinders but this did not prevent his continuing the race and finishing in eighth place. Vail's other troubles were a leaky pump gland, a carbureter adjustment and a dirty carbureter strainer. The leaking pump gland bothered Vail in very much the same way as it did Haibe.

Broken Connecting-Rods

The third car to drop out in the race was Pullen's Maxwell, which had a broken connecting-rod and as a result a broken crankcase. Resta's second stop was his last, as he was eliminated when the race was 1 hr. old, by a broken connecting-rod. Previous to this he had made one stop for a right rear shoe. Only 2 min. after Resta went out, a burned-out bearing eliminated Rickenbacher and his Maxwell, which had not



Two of the derelicts, Mulford's Peugeot and Oldfield's Delage, abandoned at the pits

previously pulled up to the pit wall. The first stop of Jack Lecain's Pugh Special also indicated a fatal mishap as he was forced to leave the race because of a broken clutch collar.

Ralph De Palma's large following were all disappointed, for after changing a right rear tire when he had traveled about one-third the distance, he very shortly after had to make another stop for water, gasoline and oil, and later was put out of the race by a broken ball bearing. Evidently he had suspected the trouble on his previous stop, for while the water, gasoline and oil were being added he had lifted the hood to inspect his motor.

Bob Burman Unfortunate

A genuine sigh of sympathy went up from the stands when Bob Burman after running a magnificent race for 346 miles, and having but two laps to go to finish, was forced to drop out with a loose flywheel, which put his clutch out of commission. Burman had not made a stop before this time except to take on gasoline and oil after he had traveled nearly 300 miles.

Little time was lost on this stop, and he still had an excellent chance to win the race, or at least to finish in second place as he was neck and neck with Tom Rooney's Stutz at the time. The two remaining Stutzes at this time were in first and second positions. The third Stutz, driven by Earl Cooper, had been forced to leave before the race was half an hour old, with a broken valve.

Willie Haupt nearly came in for some prize money with his Duesenberg car, but a loose carbureter caused him to push his car when he was well along toward the end of his run. He had not been making many stops before this as he did not draw up to the pits until more than 2 hr. after the race had started, when he took on gasoline, water and oil. Shortly after this a broken inlet rocker arm reduced his number of available cylinders to three. Again he made a stop for a right and left rear tire and then another stop for a carbureter adjustment which was the forerunner of the trouble which finally put him out when he started to push his car with its loose carbureter, thereby rendering useless many a weary mile he had plugged along with a three-cylinder motor.

America's Engineering Triumph

Europe's Finest Cars Completely Vanquished By the Product of American Engineering Skill

By A. Ludlow Clayden

NEVER before in America has there been better representation of the finest European racing cars than at the Sheepshead Bay Speedway, despite the fact that the majority were of one make, for that make is the leader of all racing engineering. The conquest of the old Delage cars means nothing, for they were weary with that stiffening which comes with age, alike to machines as to men, but the failure to finish of the Peugeots is a very different matter. Granting that they were older than the Stutz and Duesenberg cars, they are still running as fast as ever before, and the only explanation of their collapse, one after another, is that they were run off their feet, so to speak, by the superior stamina of their American competitors. The race gave precisely the same impression to the beholder as did the French grand prix of 1914, where the Mercedes team ran with such regularity, and so fast that the Peugeots were unable to keep up with them.

Materials of Construction Important

In all racing cars the aim is to work every bit of metal at the extreme limit which it will withstand for the duration of the race, and most cars will support a burst of speed for 10 miles or so which they cannot maintain for 100 miles. In a long race a car is driven as much below its maximum as will suffice, and is only forced to the limit as a last resource. Thus when we see all the Peugeots eliminated in the effort to hang on to the Stutz it can only be argued that the latter were capable of sustaining greater stresses for longer periods.

This means that American steel makers have found materials at least as good as and perhaps better than the famous B. N. D. steels of which the Peugeots are composed so largely, and this is at least as important a thing for the American automobile industry, as is knowledge that American engineers can equal the French in excellence of design.

It is quite possible that one of the difficulties which always present themselves when the attempt is made to keep an old racing car up to its original form when it is far from the land of its origin, is that of finding the proper steel to replace broken or fatigued parts. It is undoubted that the Peugeots which competed last week, and the Mercedes with which De Palma won the Indianapolis race contain the finest steel that Europe has ever produced, mostly of German manufacture, for the Derhion brothers who prepared B. N. D. bought largely from German sources of supply. A glance at the sectional drawing of the Stutz engine gives an idea of the intensity of stressing in every part, and it is at least as great as that prevailing in any foreign motor.

What Is the Limit?

Boillot, the celebrated French driver and engineer discussing the new cars of 1914 with THE AUTOMOBILE'S Paris correspondent shortly before the Lyons race told him that it had been "very difficult to get more power than last year." In that contest the Peugeots and Mercedes had little to choose between them on the score of maximum power, and it is probable that the Stutz motors even, have not quite equalled the *maximum* figure of either, but the Mercedes won in France because it could *endure* and now the Stutz have won for precisely the same reason.

The sixteen-valve engine has brought us to a point where there are two questions to be faced, can we get more maximum power from a cylinder of given size and if we can, shall we be able to find materials to stand the stress?

To sidetrack the question of the motor, for a moment, an interesting study is the much better showing of the leaders in the races of this year, compared with that of the other

cars which contrived to finish within the prize list. Why is it that the speed of the winner is always so *very* much greater than the average speed? In every race on a speedway this year the cars have separated into bunches capable of division into three main crowds, the leaders, the middle men and the tail, and there have been duels between car and car in each class. Of course, in attempting to explain this, only very broad conclusions can be reached, but it is at least a fact that usually we see the entirely special cars in front, the cars with specially designed motors but not special chassis, in the middle group, and the cars with neither highly special motor nor special chassis in the tail.

Take a concrete example and contrast the appearance of the Peugeots and the Stutz with the Duesenbergs. The former have the lines of a thoroughbred from radiator to rear and their stripped chassis have the mechanical beauty of the motor continued throughout the transmission. The Duesenbergs have an engine of the highest class, but regarding either the chassis or the car complete it cannot be doubted but that the motor is wasting more of its wonderful power in mechanical or in air friction. Give the Duesenberg sixteen-valve motor a chassis as good as the Peugeot and it would show itself still more capable.

In concentration upon the motor the chassis is always liable to be neglected; it has been neglected by touring car engineers and by the makers of racing cars, with a few exceptions. Really, it is the truck men who have done most toward chassis development for the circumstances of their business forced it on them. This present season has seen a wonderful cleaning up of passenger car chassis with elimination of much needless detail, and the proof is there for any who care to appreciate it that the racing cars of 1916 will need as much study in the chassis as in the motor.

Approaching the Limit of Power

Much motor development in the near future is unlikely. Since the coming of the sixteen-valve engine, now nearly three years ago, the struggle has been, not so much to get power from it, as to make it able to contain that power without breaking. If the 300 cu. in. motor remains the 1916 size, any more power that is got from it will be a very small amount, probably 2 or 3 per cent at most, and even that is a good deal to hope for.

So the obvious thing to do is to try to devise means for using the power we know we can get safely with the minimum of waste. Lighter chassis would help, not that weight makes much difference when a car is running at full speed, but it does affect acceleration vastly. Watching the Astor Cup race it was easy to see how acceleration was of value in enabling a fast car to slip by a slower one in the most favorable spot, and often passing was prevented for half a lap or more solely by the inability of the faster cars to accelerate quite rapidly enough.

A week ago one might have written that lighter weight would reduce the time lost in tire changing, but when eight cars finish a record-breaking race with only two tire changes between the lot of them, this becomes of less importance. Though, of course, had the season been August the tire changes must have been more frequent.

During the race, two of the Peugeots were pushed in to the pits some considerable distance. Just before the race Resta was observed to place the front wheels of his car dead on the starting line by a gentle pressure of one hand which moved the car forward about a foot. This lightness of "rolling" is not peculiar to the Peugeot, as the Stutz and various other cars are almost, if not quite as free, but it stands out in high relief by comparison with the effort needed to push the average racing machine as seen on the speedways. It means that not a bearing in the transmission, not a ball race in the wheels but is perfectly adjusted and perfectly lubricated, and it means miles an hour more at high speed. Put the Peugeot motor in some of the chassis that are considered good enough for first rank racing, and the car's maximum speed would be less than 100 m.p.h., its acceleration cut in two, and its reliability also halved.

Prediction is dangerous, as so many surprises occur in automobile engineering, but the 1916 season *ought* to show an increase of average speed more on account of chassis development than because of motor innovations.

Failures Mostly of Material

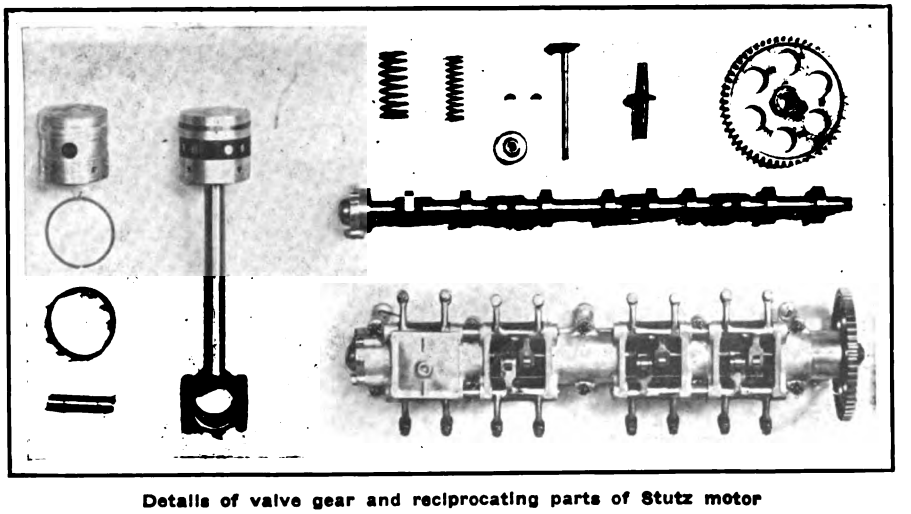
Had the Peugeots been new cars it would instantly have been said that their connecting-rod design was too weak, but we know from past records that this most certainly is not true. Ralph De Palma was eliminated by a broken ball bearing in the motor, yet hundreds of similar bearings have run thousands upon thousands of miles at racing speeds without a sign of trouble. Two or three valves or valve rockers broke, yet scores of others ran through the whole race as they had run through others. So it is not just to blame upon the design any one of these accidents.

Actually blame is not to be used for any failure in machines so highly stressed, rather than saying that the steel in the broken parts was not good we should say that the material of those that did not break was marvelous. But the lesson to be read is that we could do with still stronger steel, our engines develop a trifle too much power.

If any man had doubt of the aluminum alloy piston he ought now to be convinced that he need no longer hesitate. During this year's racing it has given much less trouble than did the best steel pistons in European contests during 1913 and 1914. The alloy piston is no lighter than the steel, it is *more reliable when of equivalent weight;* that is why it is now common on the speedway, and this may easily be written down as the most striking development of the year.

It follows along the line of the foregoing reflections, in that the aluminum alloy has proved to be a better material for making pistons than anything we had before. Its discovery has increased the reliability of the sixteen-valve motor. Perhaps we shall find next year that the aluminum alloy cylinder is also to play a part, that the better heat conductivity of aluminum may be utilized, so as to reduce the temperature of the valves, for instance. Time alone will show, but it is a line of development that is being followed by some and closely watched by others.

Another great development of the year is that of ignition,



Details of valve gear and reciprocating parts of Stutz motor

for this has been an outstanding trouble ever since the sixteen-valve engine was first used. This type of motor having more power per cubic inch of displacement has also a higher working temperature, so that spark plugs suffered in consequence. Throughout the 1913-1914 European racing season only two or three manufacturers of cars were able to keep the plugs in working condition for any length of time, similarly at Indianapolis this year, plug trouble was frequent, but at Chicago it had lessened and did not attack the Sheepshead Bay leaders. Plugs used at present are practically no better than those used six months ago, the difference is in the method of their use. Very high pressure motors need very copious supplies of oil and, if the oil comes into contact with any part that is exceptionally hot, it will carbonize promptly. Thus if the tip of the spark plug happens to be the hottest point in the combustion space it will soot up easily.

To overcome this difficulty there are two courses open; one is to prevent oil from reaching the plug and the other to keep it cool. In the most successful motors both precautions are taken and the plugs are mounted in the center of the cylinder head. In this situation they can be surrounded entirely by water, with only a thin wall of cast iron for the heat to penetrate, and also they are at the point most distant from the periphery of the piston, which is the line past which the oil comes. A plug placed horizontally in the side of the head is right in the line of fire of the oil, and any which does reach it has a lesser opportunity for draining off again, but it may be equally well cooled. A plug located in a valve cap, and so insulated from the cooling water by a thick section of metal, has a harder duty to perform, and if it is also horizontal it is in the worst case possible. These things have been found out slowly, but the principles now find general acceptance and their adoption has produced the satisfactory results now obtained.

Carburetion has changed very little this year. There have been no new wonders in the gas-making field and no great changes in carbureter construction. It is noteworthy that America is now producing carbureters which will compete with the Claudel in power supply, but apart from this there is little to chronicle.

Lubrication also has provided no surprises, the oil employed is almost always a derivative of castor oil of some kind, sundry trifling details of design have helped to prevent oil sent to an overhead camshaft from flooding the valves, and means have been found for ensuring a proper supply of oil to the crankpin bearings in motors with ball bearings on the main crankshaft journals. All these being small matters of individual detail and not questions of principle.

To what extent the increasing use of ball bearings is due to the desire for compactness and elimination of three bearings requiring high pressure lubrication, and to what extent it is mere blind Peugeot imitation would be very difficult to say. The mere fact that Peugeot have used ball bearings sways the mind of the best of engineers when deciding which he will adopt, and it is safe to say that ball bearings would have been employed in the majority of ordinary automobile motors to-day, were it not for the noise which seems to be inseparable from their use.

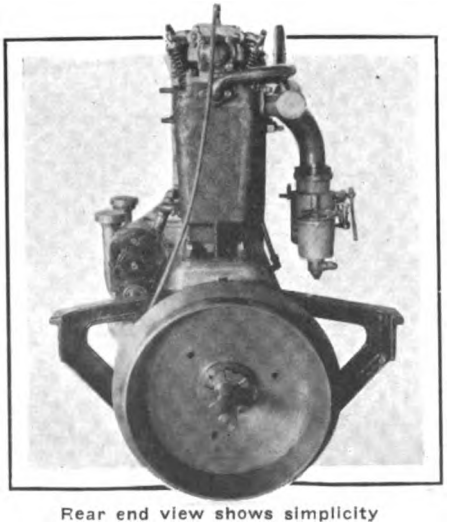
To sum up, the racing season has consolidated the position of the sixteen valve motor introduced by Peugeot in 1913. It has proved American automobile engineering to be able to meet and beat the foreigner. It has established knowledge of materials not possessed before. It has seen no great mechanical novelties, but it has developed and brought to a high pitch of perfection the most modern type of engine.

Stutz Racing Motor Has Light Parts

Large Valve Opening—Many Ball Bearings—Centrifugal Lubrication and Two-Piece Crankshaft, Features of Design

MADE by the Wisconsin Motor Co., Milwaukee, Wis., the Stutz racing engines which have performed so wonderfully well this year, rank with the very finest racing creations of Europe and are now leaders of the whole world. Yet, a glance at their drawings shows that simplicity is a characteristic, that few parts and very light proportions everywhere are the rule. The bore is 3 13/16 in. and stroke 6½ in., giving a total capacity of 296.81 cu. in. or 74.2 cu. in. per cylinder. The maximum power is obtained at a piston speed of 3250 ft. per min., which corresponds to 3000 r.p.m., and is about 130 hp., as shown by block test in the maker's plant. This is practically 0.44 hp. per cu. in. displaced, or 1 hp. per 2.2 cu. in. The brake mean effective pressure which is usually known as ηp is 115 lb. per sq. in. at maximum hp. and has then fallen off a good deal. At just over 2000 ft. per min. piston speed it begins to droop, the value of ηp below this speed being over 130 lb. per sq. in. These figures compare extremely well for the values quoted for foreign engines.

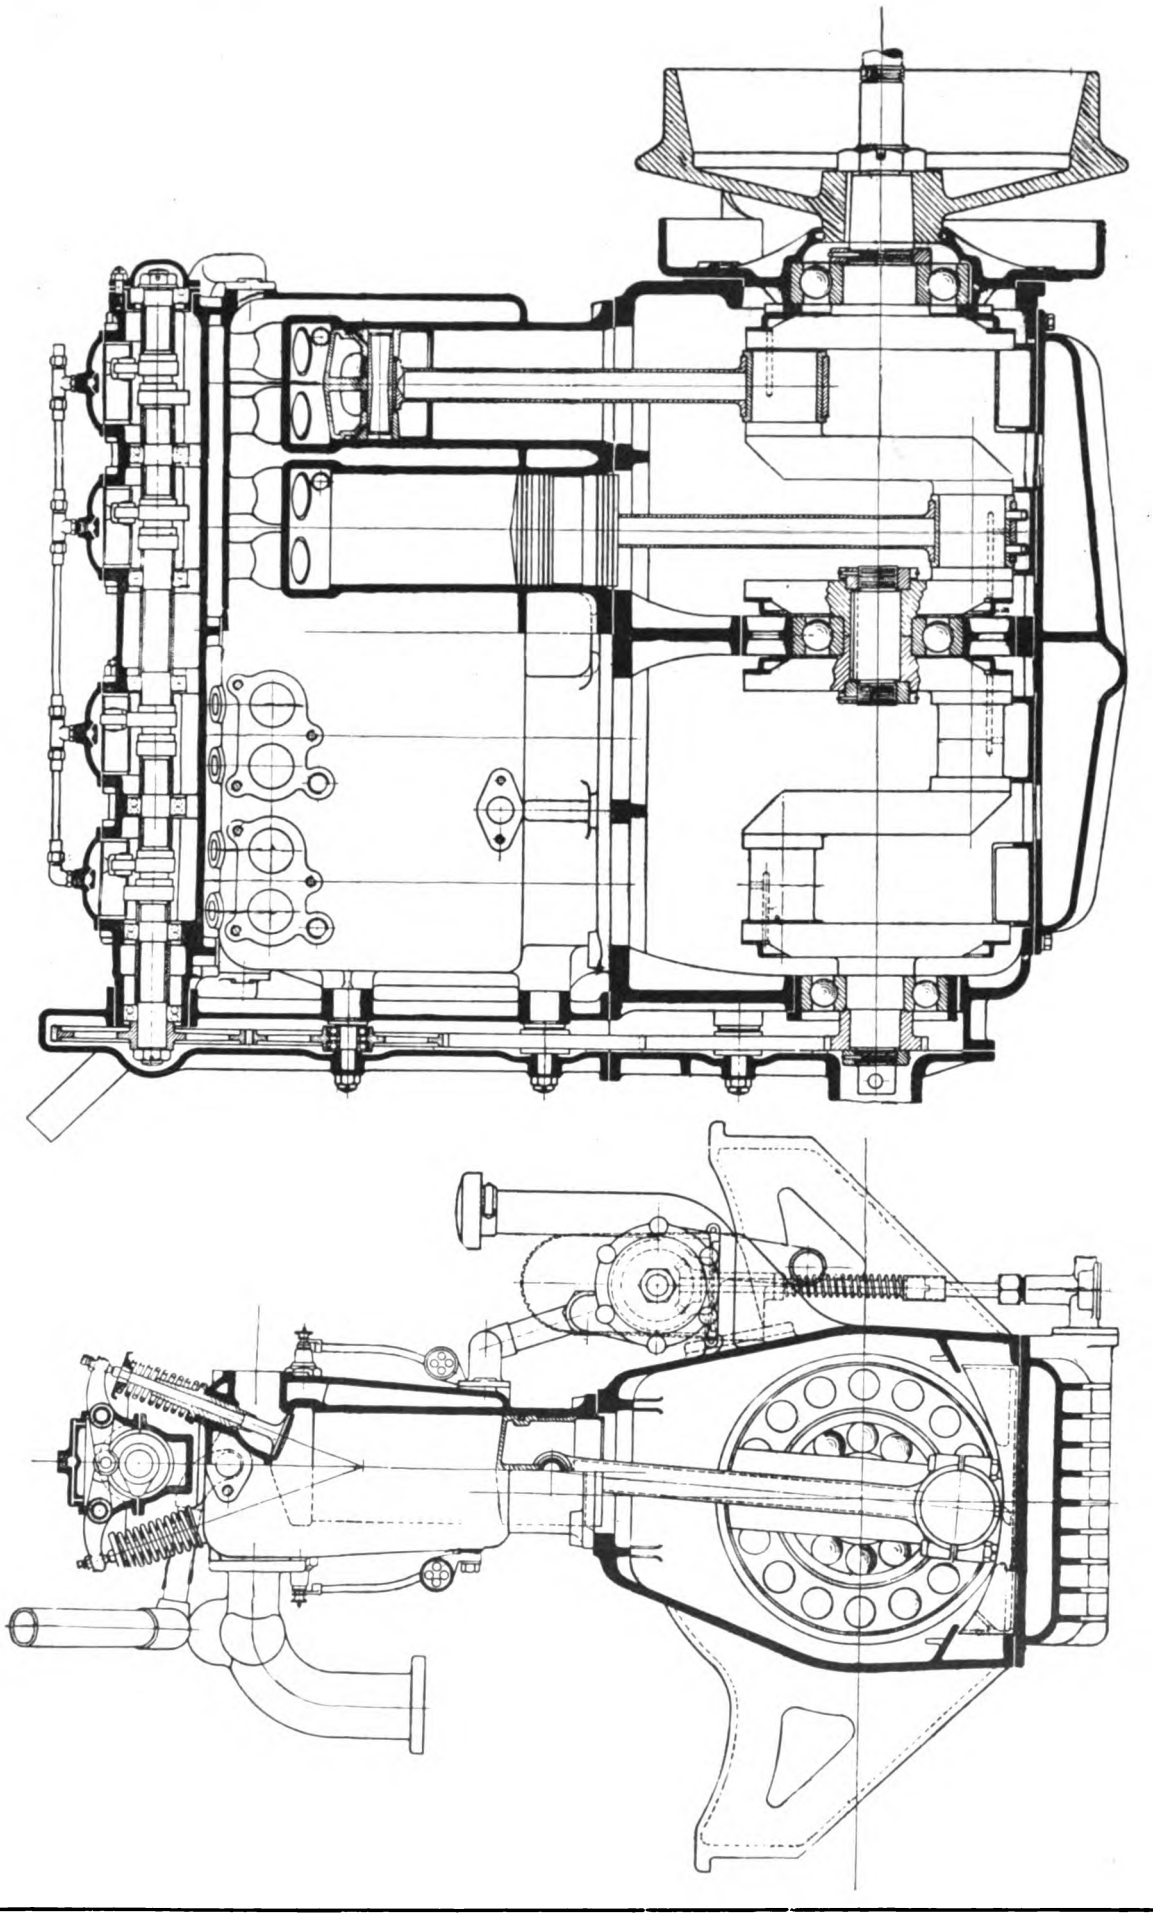
Each of the four valves is over 1.5 in. in diameter. as the port behind the valve has this dimension. The area of the port is 1.767 sq. in. and the lift of the valve ⅜, which gives a peripheral opening of exactly the same value as the port area. Meanwhile as the area of the piston is 11.4 sq. in. and that of the two valves together 3.534 sq. in. the speed of the intake gas at the crankshaft speed corresponding to maximum power is (in round figures) 180 ft. per sec. This is far from a high velocity as many touring car motors are designed on a basis of 200 ft. per sec.



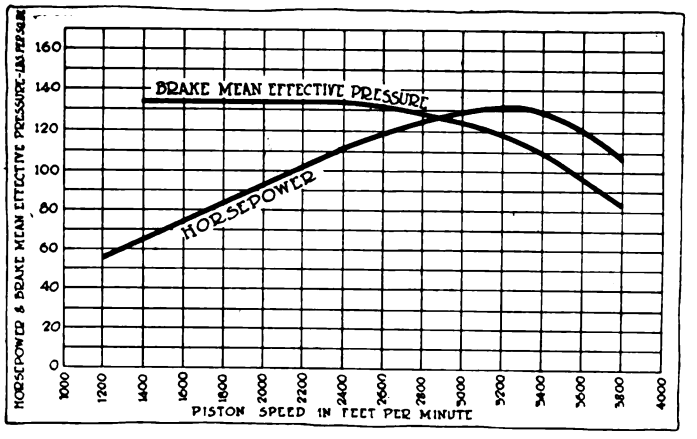
Rear end view shows simplicity

Perhaps the most remarkable feature of the design, as seen in the section, is the extraordinary smallness of the spur gears that drive the camshaft. These have a width of face of only 0.5 in. and their pitch line velocity is 2650 ft. per min. at a crankshaft speed of 3000.

The crankpins are 2.25 in. diameter and the lower end bearings 2⅜ in. wide, the babbitt metal being run straight into the ends of the hollow connecting-rods. The way in which the two halves of the crankshaft are held together is shown in the section, and it may be noted that the balls in the bearings are 1 in. diameter. Of course the use of a divided shaft makes the assembling simple and, much more important, al-



SECTIONAL VIEWS OF WISCONSIN-STUTZ RACING MOTOR 3 13/16-IN. BORE AND 6 1/2-IN. STROKE



Curves showing horsepower and brake mean effective pressure plotted against piston speed in feet per minute

lows the employment of a fairly small diameter ball race. At the bottom of the groove the diameter is about 3 in., so that the peripheral velocity at full power is only 2300 ft. per min. which is not excessive.

The life of a ball bearing is affected vitally by the speed at which the balls roll and if a solid crank were used, in which the center bearing had to be "threaded" into place, the velocity would need to be at least twice as great.

Lubrication Is Simple

For a racing motor the lubrication seems almost absurdly simple. Each lower end carries two splash dippers which are backed by holes that lead directly to the crankpins, but each crank web also carries a gutter ring whence oil is forced by centrifugal pressure through small holes drilled in the pins. So there are three supply holes to each lower end bearing, their diameter being approximately 3/16 in.

Overhead, the camshaft has a ball bearing between each set of cams, and over the top case is a header which throws a copious stream of oil directly upon the cams and the roller ends of the rocker arms. From the camshaft case excess lubricant drains back to the crankcase. Like the crankshaft and camshaft, the timing gears are also mounted on ball bearings, so the only plain bearings in the whole motor are the lower ends and the piston pins. The latter are interesting in that the pin is fixed neither to the piston nor the rod, but is free to move in either.

In the longitudinal cut it may be noticed that small oil holes lead to the ends of the piston pins from points just beneath the single ring. The piston shown in the drawing is steel made on the same principle as the Sunbeam, with a center leg to rest against the wristpin and act as a heat conductor to aid in keeping cool the center of the piston head. Magnalite pistons were used in the race and one of these is shown in the photographic illustration. There it may be seen that the wristpin is constrained against endwise movement by a thin steel ring slipped over the middle of the piston.

Very Simple Crankcase

The designers are to be complimented upon the idea of putting the oil pump outside the crankcase for two reasons. Firstly, it enables the case to be designed solely from the viewpoint of rigidity, and allows that rigidity to be obtained with a minimum of metal; the drawings are enough to show how very strong the section of the crankcase is.

Secondly, having the pump external and in the free atmosphere must have a quite considerable influence on the temperature of the oil. It may also be observed that the quantity of oil actually carried in the base chamber is quite small, and the latter is ribbed deeply for cooling purposes. It is thought, from Peugeot experience, that a continuous supply of fresh, unused oil is necessary for racing motors of this type, where high pressure feed to the lower end bearings is an impossibility. This Wisconsin-Stutz holds just about enough oil internally for the maintenance of circulation and the fresh supply is enough to control the temperature.

Harry Grant, Twice Vanderbilt Winner, Dies of Burns

NEW YORK CITY, Oct. 8—Harry F. Grant, twice winner of the Vanderbilt cup race, died last night in the Coney Island Hospital as the result of burns he suffered on Sept. 28 when his Maxwell took fire at the Sheepshead Bay Speedway.

Grant's death comes as a surprise, as it had been reported only a few days ago that he was recovering.

The accident which caused his death occurred just after he had completed one circuit of the 2-mile track on a practice spin. As he went up the banked turn on his second practice lap his car suddenly was enveloped in flames. Situated as he was on the bank of the track, it was impossible for him to apply the brakes and instead he kept his car, which was going faster than 90 m.p.h., under control until he passed the curve. Then he jammed on the brakes.

The fire was due to a loosened gasoline line and a backfire at the carbureter. The car was only slightly damaged.

HARRY GRANT

One of the most famous of American automobile racing drivers died on Thursday night, Oct. 8, in the Coney Island hospital due to the burns sustained in a practice spin at the Sheepshead Bay motor speedway on Sept. 28 preliminary to the Astor cup race and after he had qualified his Maxwell for the great contest. Grant's long racing career was chiefly distinguished by his winning of the Vanderbilt cup race in 1909 and 1910, the only time this contest has been captured by the same driver twice in succession, although he won a number of other important races

Grant's racing career, which began in 1907, was brilliant and free from accidents. His only other serious mishap was at Corona last fall, when one of his wheels broke while traveling in a race at 95 m.p.h. The car turned over and burst into flames when the gasoline tank was rent, but Grant escaped unhurt. Another misfortune overtook him in California in a Vanderbilt Cup race, when one of his helpers filled his gasoline tank by accident with water at a crucial moment in the race, putting the car out of commission.

Harry Grant was born in Cambridge, Mass., in 1877. While a young man he became interested in automobiles and worked for several years as a salesman and demonstrator in the Boston offices of the Alco company. In 1907 he started racing on small dirt tracks. His success encouraged him to enter the Lowell road race in 1908 and he made the fastest lap in the contest. A tire explosion lost the 1909 Lowell race for him.

In 1909 and 1910 on a Long Island course he won the Vanderbilt Cup race, each time driving an old stock Alco car. He is the only driver who ever won two Vanderbilts in succession. One other driver, Ralph De Palma, has won two Vanderbilt Cup races. Grant is survived by his wife.

N.A.C.C. Allots Show Space

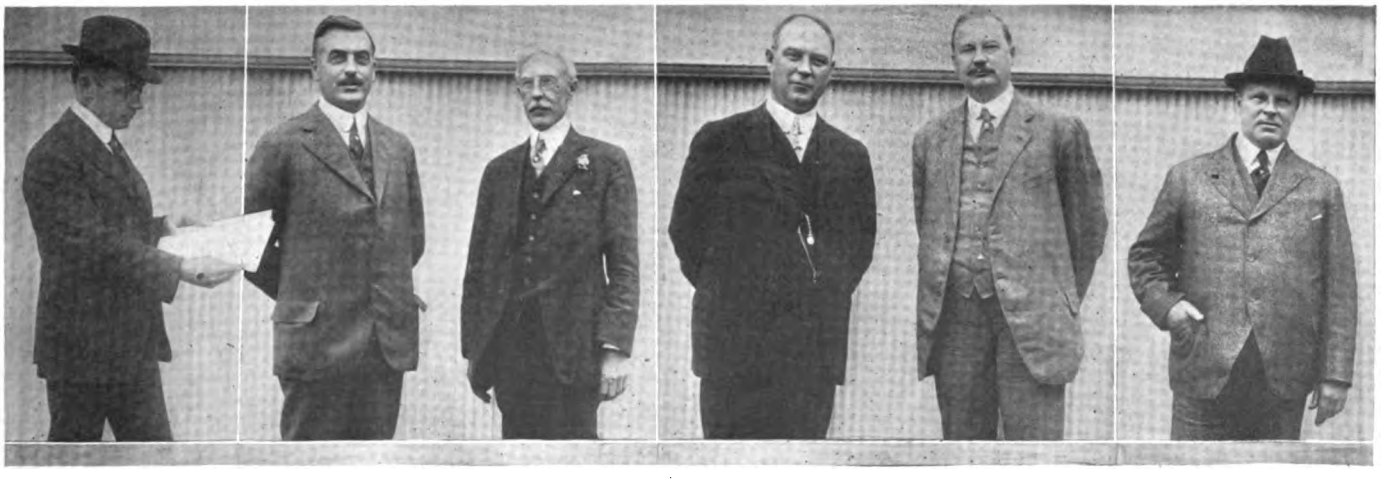
NEW YORK CITY, Oct. 8—The meeting of the National Automobile Chamber of Commerce, Inc., for the drawing of exhibit spaces at the New York and Chicago shows proved one of the biggest from number point of view of the year. Practically all the members of the association had their representatives present to look after the drawing of space, and when the members had drawn an opportunity was given non-members to secure whatever space was remaining at the Palace and Coliseum shows. Before the drawing took place a spirited discussion occurred as to whether the order of drawing should be in proportion to the total amount of sales made by the different companies during the year ending June 30, 1915, or whether the order should be based on the volume of passenger car business only, truck business being excluded. Heretofore the drawing has been in proportion to the total volume of passenger car and truck business. When the vote was taken it was found that majority favored including a passenger car business only as passenger cars only are on exhibition. Truck manufacturers contended in the debate that according to precedent the trucks should be included. The new ruling made considerable difference in the drawing and placed several concerns whose truck business is greater than the passenger car business some distance down on the list, whereas formerly they were up in the first ten.

The honor of selecting the first position for both shows fell to C. S. Jameson, of the Willys-Overland Co., the report showing this company the leader in the volume of business for the year, a position it has now held for the third season. Following Overland came Buick, Studebaker, Cadillac, Maxwell, Hudson, Reo, Dodge, Chalmers, Hupmobile, Packard, Pierce, Paige, Franklin, Chandler and Saxon.

Electric cars allotted space were Anderson, Baker, R. & L., Ohio, Milburn, Waverley and Woods.

In all seventy-five different car concerns secured space at New York, these not including probably six electric makes which will occupy a prominent space in one group on the second floor. Compared with the drawing a year ago, the number of makes is not quite so large, ninety-five makers securing space at that time. Practically all of the available exhibit spaces have been taken with about three exceptions, this number of spaces remaining open on the third floor.

There are a few new names in the show



W. C. Marmon
Pres. Nordyke & Marmon Co.

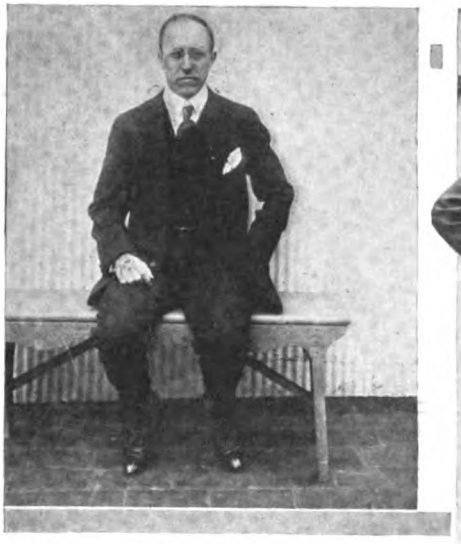
Wm. E. Metzger

J. C. Schmidt
Pres. Pullman Motor Car Co.

W. H. Vandervoort
Pres. Moline Automobile Co. and Pres. S. A. E.

C. C. Hanch
Treas. Studebaker Corp. and Director N. A. C. C.

E. S. Jameson
Vice-Pres. Willys-Overland Co.



Left—
Harry W. Ford
Pres. Saxon Motor Co.

Right—
H. M. Jewett
Pres. Paige-Detroit Motor Car Co.

In Oval—
H. W. Hayden
Vice-Pres. and General Manager Pullman Motor Car Co.

Right—
F. C. Chandler
Pres. Chandler Motor Car Co.

this year including All-Steel, Empire, Grant, Sterling, Sun and Trumbull. While these new names have appeared others have dropped from the list. Among those missing for the 1916 show being Cartercar, Crawford, Krit, Lyons-Atlas, S.G.V., Speedwell, Herreshoff, McIntyre, Partin-Palmer, Sphinx, Cresson-Morris and Mack.

There are sixty-three members of the association who were in on the original drawing, their order of drawing being in proportion to the amount of business done. After these came five members who have recently joined the organization and when these had secured space, non-members were given an opportunity, among those drawing being All-Steel, Davis, Empire, Enger, Herff-Brooks, Lewis, Metz, Owen, Remington, Standard, Sterling, Sun and Trumbull.

Practically the same space arrangements will prevail in Grand Central Palace, New York, as have been used in the past. The main floor second floor, and a goodly portion of the third floor of the building will be used for car exhibits. Accessories will be on the third and fourth floors. In Chicago the show will be held in three buildings, the Coliseum, Coliseum Annex and the First Regiment Armory, the cars having practically the same space as formerly.

The complete list of car exhibitors at the New York and Chicago shows follows:

Car Exhibitors at New York

Main Floor—Automobile Section

Briscoe Motor Co.....Jackson, Mich.
Buick Motor Co.....Flint, Mich.

95 Accessory Firms To Exhibit

NEW YORK CITY, Oct. 8—The Motor & Accessory Manufacturers through its show committee to-day allotted exhibit spaces to ninety-five of its members for the New York and Chicago shows. The list is practically the same as heretofore, showing eighty-seven exhibitors at New York, and eighty-three at Chicago. There are seventy-five concerns that will exhibit at both shows, twelve will exhibit at New York only, and eight at Chicago only, the complete list showing this division.

There are some familiar names which appeared on the list last year, but are not on this year. Some of these are: Standard Welding Co., Springfield Metal Body Co., Coes Wrench Co., Gemmer-Detroit Starter Co., National Coil Co., Dunlop Wire Wheel Co., Bearing Co. of America, Bock Bearing Co., Golde-Patent Co. On the other hand there are some new concerns that did not appear on the list last year including John O. Heinze Co., Brunner Mfg. Co., National Screw & Tool Co., and others.

The list this year contains practically no names of tire makers, a very few of the manufacturers of magnetos, axles, steering gears, and not so many manufacturers of starters as heretofore. The names represented include the accessory field thoroughly. This list will undoubtedly be supplemented when the allotments are made to manufacturers who are not members of the Motor & Accessory Manufacturers.

In addition to allotment of space four concerns were admitted to membership, these being: Brunner Mfg. Co., manufacturer of air compressors, Utica, N. Y.; E. A. Laboratories, Inc., manufacturer of automobile electric and hand horns, Brooklyn, N. Y.; General Bakelite Co., manufacturer of Bakelite, New York, N. Y., and Leece-Neville Co., manufacturer of electric starting and lighting systems, Cleveland, Ohio.

The complete list of exhibitors at both the New York and Chicago shows, at New York only and at Chicago only is as follows:

New York and Chicago

American Bronze Co.....Berwyn, Pa.
Apple Electric Co.....Dayton, Ohio
Automobile Supply Mfg. Co..Brooklyn, N. Y.
Benford Mfg. Co.....Mount Vernon, N. Y.
Blackledge Mfg. Co., John W....Chicago, Ill.
Brown, William H.....Cleveland, Ohio
Brown-Lipe Chapin Co.....Syracuse, N. Y.
Brown-Lipe Gear Co.....Syracuse, N. Y.
Brunner Mfg. Co.....Utica, N. Y.
Buda Co.....Harvey, Ill.
Byrne, Kingston & Co.....Kokomo, Ind.
Carr Co., F. S.....Boston, Mass.
Champion Ignition Co.....Flint, Mich.
Cowles & Co., C.....New Haven, Conn.
Cramp & Sons Ship & Engine Building Co., Wm.....Philadelphia, Pa.
Detroit Lubricator Co.....Detroit, Mich.
Dixon Crucible Co., Joseph.Jersey City, N. J.
Doehler Die Casting Co.....Brooklyn, N. Y.
Double Fabric Tire Co.....Auburn, Ind.

Aluminum Pistons for Racing and High-Speed Work—Connecting-Rod Stresses Complex—Four Valves Per Cylinder—Rotary Motors

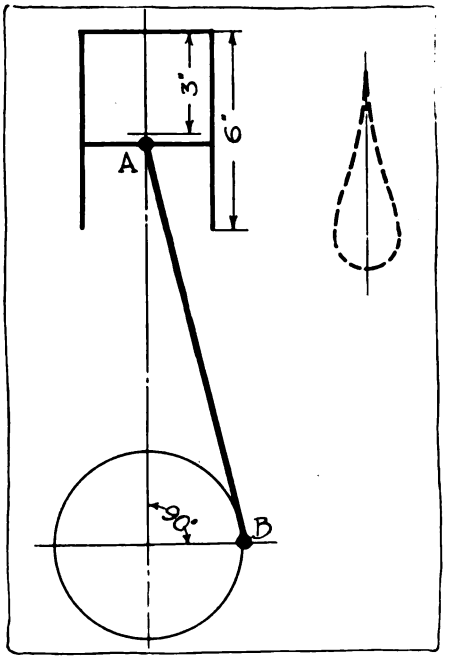
By Charles Vivier

ARCADIA, CAL.—Editor THE AUTOMOBILE:—The phenomenal crankshaft speeds attained by the modern racing motor have convincingly demonstrated the importance of the rôle played by the reciprocating parts. In the ordinary four-cycle motor, these parts are: the pistons, the connecting-rods and the valve mechanism. As the inertia forces and stresses increase rapidly in function of the speed and the weight of the moving parts, the problem is therefore to reduce their weight to the smallest possible minimum, taking into consideration of course the safe limits of the tensile strength of the parts subjected to the hardest work. This solution is no easy one, it being a fact that the motor invariably fails first under fast work. Yet great progress has been accomplished in the last few years in motor manufacture, thanks to the valuable help of modern metallurgy and the careful designing and machining of the delicate parts.

Regarding the pistons, remarkable strides have been made. Their weight is now considerably reduced in comparison to the cast iron product. Nickel alloy steels, with low co-efficient of expansion, are sharing honors with the aluminum pistons, which won both San Francisco races in Resta's Peugeot.

The aluminum piston has one great advantage over the steel piston: it radiates its imparted heat readily. If properly designed, the aluminum pistons will remain relatively cool under heavy work, thus eliminating the trouble of pre-ignition due to red-hot pistons, a danger ever-lurking around a high-compression motor. A well-known western firm specializing in aluminum pistons claims that its pistons will not melt zinc after a motor has been allowed to reach its greatest heat; if the same motor is run under identical conditions with steel pistons, the zinc will be promptly melted. Every racing driver knows that high compression is a valuable desideratum for power, but pre-ignition mercilessly dictates its limitations. In the Lyons Grand Prix, which was run on a warm day, much trouble was experienced from super-compressioned motors. The winning Mercedes had a geometrical compression not exceeding 6 kilograms per square centimeter, or 85 pounds per square inch.

With regard to the connecting-rod, no part of a motor is subjected to a more complex combination of forces and stresses. Referring to the illustration, the line AB represents the connecting-rod. Points A and B, the centers of the wristpin and the crankpin respectively, can be considered integral with the rod. Laying aside all explosion, compression, etc., stresses, point A is subjected to a reciprocal rectilinear, non-uniform accelerating and decelerating action, while B is subjected only to an uniform centrifugal action. Everybody knows that, owing to the angularity of the connecting-rod, the piston travels faster on the upper end of its course than on the lower one. This peculiarity is in favor of the efficiency of the motor because the piston can offer a more rapid expansion to the gases on the upper part of the explosion stroke. On the line AB, in one revolution of the crankshaft, every point of the connecting-rod below and near A, describes a figure like that at the right of the illustration resembling an elongated pear, which gradually shapes itself nearer a perfect circle in proportion as we get nearer to point B, which follows a circular path. In other words, on line AB, no two points describe the same course, identical either in shape or length, and yet, all motions between A and B are accomplished in the same length of time, the period necessary for one complete revolution of the crankshaft. In our case, if the stroke is 6 inches, the point A will travel 2 feet, at singularly variable speed, while B travels 3.1416 feet, at uniform speed, in the same length of time. One can easily imagine how, at racing speeds, the center of mass of the connecting-rod is somersaulting around its center of gravity.



Layout of connecting-rod

This state of affairs, which is inherent to the reciprocating parts mechanism, occasions tremendous strains, at high speeds, to the wristpin end of the connecting-rod, where fracture generally takes place. Most racing cars are put out of the running through the failure of one connecting-rod, and such accidents often play havoc with the motor.

Regarding the valve mechanism, great efforts have been made to reduce the weight of the reciprocating parts to a minimum, hence the idea of four valves per cylinder, and the overhead camshaft in combination with short valve stems. In a motor turning at 3,000 r.p.m., with the conventional valve lift, the energy necessary to lift the valves amounts to about 3 horsepower per pound of valve weight, which is no small item to be transmitted by the camshaft.

Rotary motors of the Gnome type offer a different aspect as regard the piston and the connecting-rods. In these motors, the cylinders revolve, the crankshaft being stationary. To one single crank is attached the main connecting-rod to which all other connecting-rods are articulated. Be-

sides, the explosion stresses, the piston and the rods are subjected only to the action of the centrifugal force. The pistons travel their stroke in the cylinders, because of the eccentric position of the crankpin in relation to the crankshaft. All intake and exhaust valves must be carefully counterbalanced with weights in order to overcome the effects of the centrifugal force. As these motors are intended for aeronautical work, they are made exceedingly light. Their massic efficiency is high, but their thermic efficiency is not. They are not suitable for automobile work; they are wasteful of oil and gas, and their large cubic inch displacement and enormous prices condemn them at the very start for terra firma work. The prices for the different Gnome models range from $2,600 for the 50 horsepower, seven-cylinder, weighing 135 pounds to $8,800 for the eighteen-cylinder, 200 horsepower weighing 550 pounds.—CHARLES VIVIER.

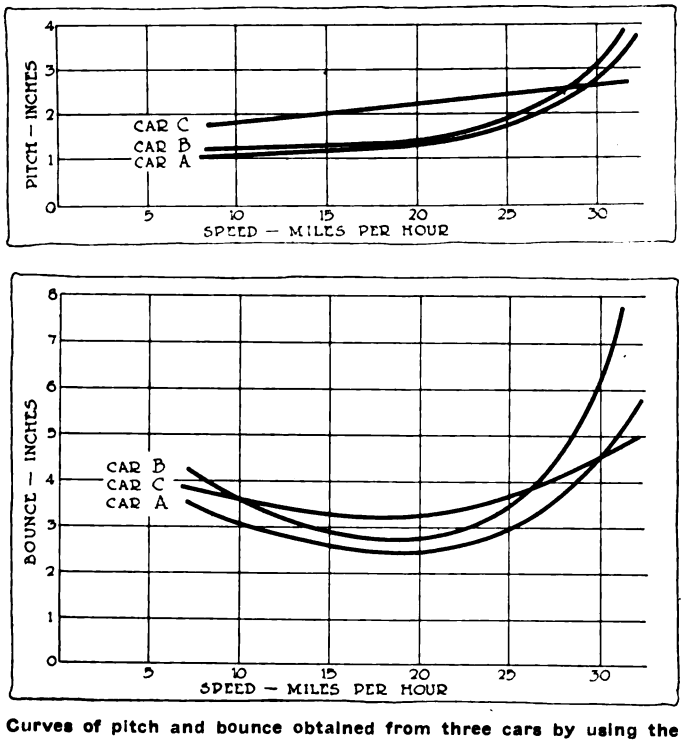
Simple Machine for Comparing Spring Action

By Hugh Pastoriza

EDITOR THE AUTOMOBILE:—The riding quality of an automobile is a somewhat indefinite thing, and is judged, by the average motorist, merely from the feel of the car as he rides in it. Obviously such a method of judgment cannot give close comparative results and the simple device described below was got up to afford a more exact method of comparison and one that any car owner can readily install in his machine.

The device as used is shown opposite. The fixed portion consists of a light pine board, 1 ft. wide by 2 ft. long, with a row of nails driven in it near each edge, and a plate of tin nailed to its center. From four of these nails, the moving element is suspended, by means of four ¼-in. rubber bands, stretched in as many directions. This moving element consists of an iron washer weighing about 1 lb., into the center of which a pencil is wedged. Obviously, any jolt will cause the pencil to move relative to the board and to make a mark on the piece of paper which is thumb-tacked over the tin plate in the center of the board. The arrangement is, it will be noted, extremely simple, and may be made up with almost no expense or trouble.

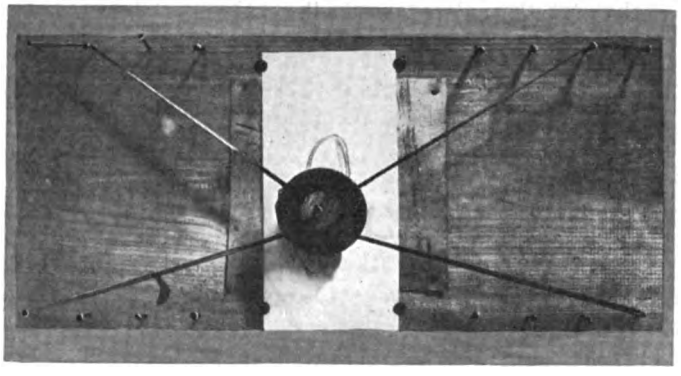
As ordinarily used, it is held in a vertical plane with its length parallel to the length of the car. To get a record of spring performance only, it may be set on the floor of the car, but as the effect of cushions ought ordinarily to be included, it should rather be held firmly upon the lap of someone riding in the car, so as to move with him. If, now, the car be run at a given speed, over a given stretch of rough road, or better still, over a standard "bump" (as, for example, a 2 by 4, with corners rounded, set out on a smooth road), then the moving element will draw a series of oval curves on the paper, differing for each car or other change in conditions. To get best results, the tension of the rubber bands should be adjusted, by moving from one nail to another, so that the largest curve drawn during the tests will not be over 3 in. high.



Curves of pitch and bounce obtained from three cars by using the apparatus

Reading the Results

The interpretation of these results is simple. Evidently the greater the horizontal width of the ovals, the more violent is the back and forward motion, or pitch of the car; and the greater their vertical height, the more violent the up and down motion, or bounce. For an ordinary road run, the average of the three largest throws in each direction should be taken for comparison, rather than the absolute maximum. The car giving the smallest ovals when run at a given speed over a given road, will, of course, be the easiest riding.



The complete apparatus for measuring spring quality

If the side movement, or roll of the automobile, is to be studied, the device may be held crosswise of the car and the horizontal width of the oval drawn will then correspond to roll instead of to pitch. Ordinarily, however, this movement is slight and of minor interest.

Records for several cars at different speeds have been measured up and the results plotted showing that:

Bounce is generally more than twice as violent as pitch.

Bounce is large at low speeds, falls at medium speeds and rises very rapidly above 30 m.p.h.

Pitch is nearly constant at low and medium speeds but rises at high speeds.

Actual magnitude and the effect of speed varies with the car, as might be expected.

The ease of riding of a car is dependent on a number of conditions: the springs; the shock absorbers; the frame; the cushions; the weight of the car; the number of passengers carried; the roughness of the road; the skill of the driver; the speed of driving.

In the ordinary case, as above described, the last four conditions would be kept constant and the results would show the comparative efficacy of mechanical design on the different cars tested. It is evident, however, that the effect of any one of the above factors alone may be studied by keeping the others constant. The effect of speed is thus found, as shown plotted. In a similar way, the relative value of different types of shock absorbers may be studied or a proper adjustment arrived at on a given type. Finally, the skill of drivers, or the roughness of roads can be tested in the same fashion. In short, with this device, one may study exactly a number of effects that he was only able to note roughly before and may find out a number of new things about his car.

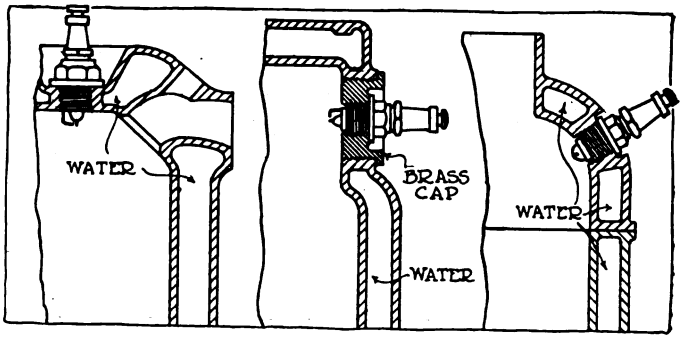
Spark Plug Should Be Vertical

Racing Experience Shows That This Is Best Position—Advocates Open End Type

By Gregory Flynn
Rajah Auto Supply Co.

EDITOR THE AUTOMOBILE:—With reference to the proper mounting of spark plugs in racing motors, our observations along this line tend to prove that placing the plug vertically through the water jacket accomplishes the best results. Although all modern racing motors are not so constructed that the plug can be placed vertically, all the designers of late have located the plug through the water-jacket, whether placed vertically or horizontally, and such mounting is essential in these days of prolonged running at maximum engine speed.

The one exception of modern practice is found in the Duesenberg motor where the plugs are placed horizontally through brass valve caps. This mounting has caused some plug trouble but not nearly as much as might be expected considering the consistent performance of Duesenberg racing cars. However, the new sixteen-valve Duesenberg motor has plugs placed vertically through the water-jacket.



Three possible positions for spark plug mounting. Left—Vertically through the water-jacket, the best position from the plug maker's viewpoint. Center—Horizontally through brass valve caps, least desirable of the three from the same viewpoint. Right—At an angle through the water-jacket, a position which has proved satisfactory

Experience shows us that our standard open-end plug has proved most satisfactory in the Peugeot, Delage and Mulford Special, having plugs mounted vertically through the water-jacket, whereas in the Maxwell racing cars where plugs are water-jacketed but placed horizontally, Mr. Harroun has found that our closed-end plug does not become fouled while in some cases the open-end type would.

As we have always advocated an open-end single-point plug we arrive at the natural conclusion that the vertical water-jacketed mounting of plugs will produce the best results.

Materials Increase 5% to 700% in Price

Small Increase in Iron and Cheap Steel—More in Good Steel and Other Metals

WITH reference to the cost of materials used in automobile construction, it has been threatened by some of the parts manufacturers that their prices for completed assemblies will rise next year, unless there is a drop in the cost of raw material.

Of course, it is not possible to estimate what an automobile maker pays for raw material simply by noting the quotations, because so much depends upon local conditions and so forth, but the market averages for the present time, and for a year ago show a general rise which translated into percentages gives a fair indication of how much more per cent the automobile trade will have to pay for materials as standing contracts are used up and new ones have to be made.

Iron Little Dearer

Ordinary iron and steel are not much more costly. Casting iron, such as is used for cylinders, is about 7 per cent dearer, and sheet steel in some sizes 5 per cent to 10 per cent dearer. Better steel such as is used for crankshafts and the more vital parts, appears to have increased much more, even to 20 per cent. Of course 20 per cent on the steel in an automobile motor does not represent much money per unit product, but 20 per cent on the total of steel bought by such a concern as the Continental Motor Co. for example, must be a staggeringly big sum.

It is when we come to the non-ferrous metals that the big differences show up in raw material costs, aluminum 250 per cent up, zinc 700 per cent up, copper 50 per cent up. Seeing that these are metals of which the market prices are sufficiently high to be quoted in pounds instead of tons, the increase on aluminum and brass is enough to make itself felt on the price of the unit article, and more than enough to make all the difference between profit and loss to a parts manufacturer bound to his present prices for selling.

A side effect upon the cost of all machine shop products is the immense increase in the cost of high speed steel, upon which all modern tools depend to provide the cutting edges. Owing to a shortage of tungsten, which is mainly an imported material, the high-speed steel price has risen rapidly from 50 cents to $1.25 per lb., and it shows every indication of going much higher. Of course this again, is not a big item in the cost of a car, but it represents so many more thousands of dollars per annum which *somebody* has got to pay.

Price Cuts Unlikely Next Year

What may be the effect on the cost of the complete car to the consumer? It is a question that cannot be answered, but if markets hold their present tone for another three months it will probably mean that 1916 will see the new 1917 models put out without much further price reduction. Improving methods of manufacture were undoubtedly the main reason for the big cuts made this year, and next season still greater economies are to be anticipated. With materials rising, however, the amount saved by manufacturing method will very likely have to go to offset the cost of the metal.

Data on Mixed Motor Fuels of Interest for American Export Trade

¶ *Nothing in the following records of results obtained in Germany by using mixtures of benzol and alcohol as motor fuel is of immediate practical interest for motor car users in the United States. But they are important for manufacturers, who figure on export trade and must build for foreign fuel conditions or tropical climates. They also deserve to be placed on file for ready reference by all who are interested in having an active competition with gasoline established in this country sooner or later, so as to hold prices in check and satisfy the ever-increasing demand for motor fuels without courting too-early exhaustion of the petroleum supply. That this demand will increase at a phenomenal rate after the war is everywhere taken for granted, considering the necessity for motors to serve in the energetic production of wealth after a gigantic campaign of waste and destruction. The United States can produce benzol from coal in any desired quantity as soon as it is wanted and also an unlimited supply of alcohol at low cost if legislative restrictions are eventually removed. The utility of the records therefore applies to possible developments in the American fuel market as well as to actual constructive requirements in motors for export. Earlier tests relating to the use of other fuels than gasoline have forfeited most of their importance through the fact that the motors and carbureters employed were specially designed or that it was necessary at least to adjust the carbureter differently for each kind of fuel. Von Loew's much more practical object is to determine the results obtainable with a motor of an accepted automobile type which by a few minor modifications is enabled to work with a variety of fuels without special adjustment for any of them.*

Before this was done no industrial results could be expected, since the designing and making of motors for any special fuel had to await the practical marketing of the fuel and no effort for organizing such marketing could be expected before the motors for it were created. Von Loew's work seems a happy contribution toward the solving of this deadlock which has long obstructed progress.

The first part of his report was rendered in substance in THE AUTOMOBILE *of August 12, pages 288 to 291 and 298 and includes a descriptive mention of the (90 mm. bore, 140 mm. stroke) motors used for the tests and the arrangements made for starting with a volatile fuel and heating the heavier fuels when necessary, as well as descriptions of carbureters which can be used.*—M. C. K.

Driving Tests with Benzol and Benzol-Alcohol Mixtures by Baron Von Loew

CONTINUING the tests previously reported, I selected mainly warm days during the spring of this year for experimenting with mixtures containing large proportions of alcohol. At the tests in the fall of 1914 it had been shown that a mixture of 1 part benzol with only 3 parts alcohol caused certain troubles when the fan behind the radiator was kept going (and subsequently the same results appeared during the cold days of last July). A sudden load would stop the motor, and it was therefore always necessary to open the throttle slowly. In other words, the motor had to be warmed up before it was safe to tackle a hill. In order to keep the motor at a higher temperature I disconnected the fan from October to April, and with this provision the motor worked again normally with the 1 to 3 mixture. Through the winter I used, nevertheless, the 1 to 2 mixture which gave excellent results. In April the fan was again connected. The 1 to 3 mixture worked then, with the fan running, equally as well as it had worked in the fall with the fan stationary. Mixtures of 1 to 4 and 1 to 5 were now also tried, and finally the car was driven on alcohol without any benzol. For all these trials the carbureter was still adjusted as for gasoline, as the principal object was to determine what fuels and mixtures will produce an efficient and economical operation of the motor without any re-adjustment of the carbureter. In the trials with unmixed alcohol the motor worked however so poorly and used so much fuel that no account in figures was kept, a change in the carbureter being evidently desirable. The figures obtained with the mixed fuels are best explained with reference to the appended tables.

Over table 1 there is drawn the profile of a road used for the tests specified in tables 1 and 4. The car was always driven at point *A* with a speed of 40 kilometers per hour and thereafter with its maximum of power. The highest tachometer reading was taken at the point *B* and the lowest at *C*, and the actually observed figures are those entered in the tables under *B* and *C* respectively. That the 1 to 2 mixture and the 1 to 3 mixture in table 1 seem of equal value may be due to some accidental factor, such as a variation in the wind resistance. All the values in tables 1, 2 and 3 were noted on the afternoon of April 30, 1915, when the temperature averaged 17 deg. C., and have not been improved by comparison with figures obtained at numerous other trials. All the figures in tables 4 and 5 are likewise those noted at trials on Nov. 1, 1914, when the temperature averaged 4 deg. C. The fan was in operation, however, on April 30, but not on Nov. 1.

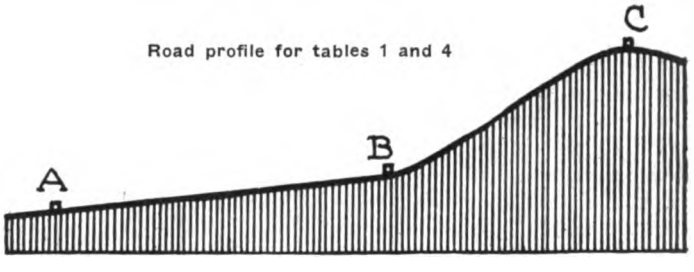


Table 1

SPEED RESULTS WITH SUMMER TEMPERATURE 17 DEG. C.

Benzol	*Alcohol*	*at B*	*at C*
Pure	none	67 km./hour	65 km./hour
1 part	+ 1 part	66 "	64 "
"	+ 2 parts	65 "	61 "
"	+ 3 "	65 "	61 "
"	+ 4 "	63 "	57 "
"	+ 5 "	60 "	56 "

Table 4

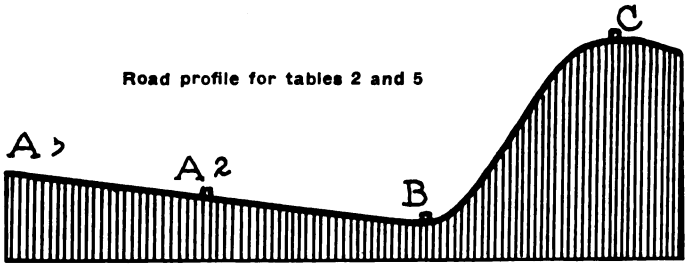
SPEED RESULTS WITH WINTER TEMPERATURE 4 DEG. C.

Benzol	*Alcohol*	*at B*	*at C*
Pure	none	65 km./hour	62 km./hour
1 part	+ 2 parts	62 "	56 "
"	+ 1 part	64 "	60 "

Tables 2 and 5 refer to tests on the stretch of road whose profile is shown over table 2, but the later tests (table 2) were started considerably nearer to *B* than those of last Fall (table 5) in order to save fuel which had become scarce. For the same reason the fuel consumption tests were conducted with only 1 liter of fuel for each, giving the figures in table 3, while the corresponding tests from Nov. 1, 1914, recorded in table 6, were made with 1½ liters for each, this being the full contents of the auxiliary fuel tank, and the original fig-

ures for table 6 have therefore been reduced one-third in order to have a direct comparison with table 3.

Table 2 shows plainly the marked drop in car speed at *C* which is characteristic of the mixtures rich in alcohol. With the 1 to 5 mixture it was at many other trials even necessary to change to the third gear speed shortly before reaching *C*, but the figures in the tables refer only to results obtained on the high gear. Table 2 illustrates how much better the car pulls with pure benzol than with the mixtures. A numerical comparison in this respect with gasoline could unfortunately not be established, for lack of this fuel, but it is well known that gasoline is considerably inferior in this particular.



Road profile for tables 2 and 5

Table 2

SPEED RESULTS WITH SUMMER TEMPERATURE 17 DEG. C.

Benzol		*Alcohol*	*at B*	*at C*
Pure	+	none	68 km./hour	50 km./hour
1 part	+	1 part	68 "	51 "
"	+	2 parts	68 "	46 "
"	+	3 "	63 "	42 "
"	+	4 "	62 "	39 "
"	+	5 "	58 "	34 "

Table 5

SPEED RESULTS WITH WINTER TEMPERATURE 4 DEG. C.

Benzol		*Alcohol*	*at B*	*at C*
Pure	+	none	82 km./hour	56 km./hour
1 part	+	2 parts	78 "	48 "

Table 3 shows much greater difference in the fuel consumption in the two opposite directions than table 6. The reason is that the morning of Nov. 1, 1914, was calm, while on April 30, 1915, a mild western wind favored the "going." And the road in that direction also has a very slight average down grade. The influence of the wind was not only plainly noticeable, but often proved a disturbing factor in the trials. With an eastern wind one could drive farther on a liter "returning" than "going," and on days when gusts of wind alternated with spells of calmness comparative figures could scarcely be established.

Table 3

DISTANCE RUN ON 1 LITER, SUMMER TEMPERATURE

Benzol		*Alcohol*	*Going*	*Return*
Pure	+	none	7.4 kilometers	7.1 kilometers
1 part	+	1 part	8.6 "	7.5 "
"	+	2 parts	8.0 "	7.2 "
"	+	3 "	7.8 "	7.0 "
"	+	4 "	7.7 "	6.6 "
"	+	5 "	7.2 "	6.0 "

Table 6

DISTANCE RUN ON 1 LITER, WINTER TEMPERATURE

Benzol		*Alcohol*	*Going*	*Return*
Pure	+	none	7.1 kilometers	6.9 kilometers
1 part	+	1 part	7.1 "	— "
"	+	2 parts	6.7 "	6.9 "

Two reasons can be assigned for the peculiarity in table 3 that the alcohol mixtures show a more favorable consumption than pure benzol. (1) The runs were made, one immediately after another, without any re-adjustment whatever—not even of a hot-air valve—and therefore the temperature of the carbureter on the unusually warm spring day was somewhat too high for benzol and more favorable for the alcohol mixtures. (2) All the runs for tables 3 and 6 were made at 40 kilometers per hour, and at this relatively low speed the carbureter furnishes a gas which is rather too rich in benzol. This conclusion is confirmed by the results recorded in tables 7, 8 and 9, referring to trials made on Nov. 5, 1914, and in June, 1915.

The intake manifold on my principal test car is provided with two air cocks, as at *HH* in the accompanying diagram, reproduced from my first report [see THE AUTOMOBILE, Aug. 12, page 289]. On the afternoon of Nov. 5, 1914, four trial runs were made with this car at 20 kilometers per hour over a stretch of road which averages level. For two of the runs the air cocks were closed and for the other two they were opened. The results, as given in table 7, show a considerable fuel saving with the cocks open.

Table 7

DISTANCE RUN WITH 1 LITER BENZOL AT 20 KILOMETERS PER HOUR

	Going	*Return*
With air cocks closed....	6.4 kilometers	6.2 kilometers
With air cocks open....	7.9 "	7.5 "

Also on runs where the motor was operated under heavy load on a mixture of about two parts benzol and one part alcohol—such runs being made June 8, 9 and 17 of this year—was it shown that the open air cocks had a favorable influence when the carbureter float was weighted with a perforated disk of lead; but, on the other hand, an unfavorable influence was noticed when the float was not weighted. The builder of the car had sent me two leaden disks together with the auxiliary tank and other things, when I began experimenting with the alcohol mixtures, and one of these disks I had on the float, as a rule, from Sept. 26, 1914, to June 17, 1915. Since this date I have generally not made use of it. Before discussing further the necessity or superfluity of weighting the float, however, the results obtained with open and closed air cocks both with and without float weights, as recorded in Tables 8 and 9, should be explained.

Table 8—Hill Climbing

EACH RUN ON 1 LITER OF FUEL COMPOSED OF 2 PARTS BENZOL AND 1 PART ALCOHOL. ALL RUNS MADE ON THE SECOND GEAR SPEED AND WITH THE FLOAT WEIGHTED

Date.	*Distance and Location*	*Air Cocks*	*Car Speed*
June 8, 1915.....	From 3.9 to 6.8	Closed	20 km.-hr.
"	" " 6.7	"	" "
"	" " 6.92	Open	" "
June 9, 1915.....	" " 7.0	"	" "
"	" " 6.9	"	" "
"	" " 6.95	"	" "
"	" " 6.96	"	30 km.-hr.
June 17, 1915.....	" " 7.0	"	" "

These runs, as referred to in Tables 8 and 9, were made on the longest and steepest hill in the neighborhood of Wies-

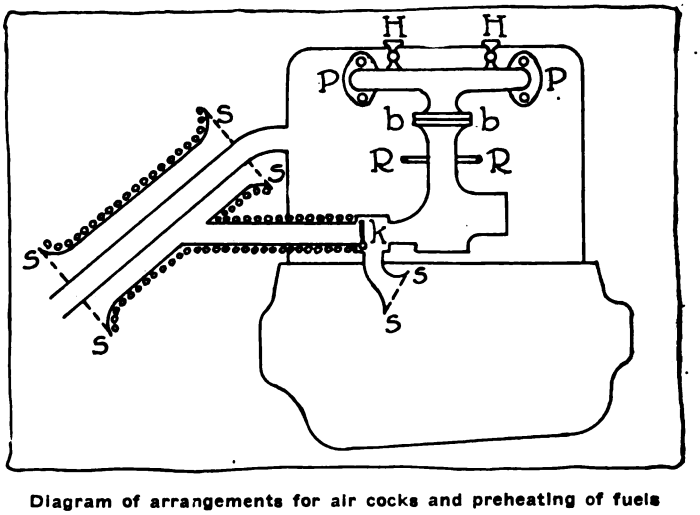


Diagram of arrangements for air cocks and preheating of fuels

baden, which is the road running to Hohe Wurzel, 619 meters above sea level, with an average grade of 1 in 10 from kilometer-stone 3.9 to 7.04. The distances in the tables are indicated by the kilometer-stones between which each run was made. On this road the car could generally work with full motor load. The tables show plainly that the effect of opening the air cocks is much less pronounced than under the conditions of Table 7, with the car running lightly on a level road at 20 kilometers per hour.

Table 9—Hill Climbing

EACH RUN ON ½ LITER OF FUEL (2 PARTS BENZOL AND 1 PART ALCOHOL). ALL RUNS ON THE SECOND GEAR SPEED AND AT 20 KM./HOUR

Date	*Distance and Location*	*Air Cocks*	*Float*
June 17, 1915.....	From 5.5 to 6.9	Closed	Weighted
"	" " 7.06	"	Not Weighted
"	" " 7.05	"	"
"	" " 7.04	Open	"
"	" " 7.04	"	"

The specific gravity of benzol is .88, of alcohol .82 and of gasoline .72. If one wants these fuels all to stand at the same level in the jet, a float intended for gasoline must carry a thick leaden disk when benzol is used and a thinner one when the fuel is to be alcohol. On the other hand, benzol requires more air for its combustion than gasoline does, and it is therefore better to have it stand lower in the jet. The two properties of benzol, namely (1) its higher specific gravity and (2) its greater need of air, have thus opposite effects, and in accordance herewith it is in my experience generally better not to weight the float.

With alcohol the situation is different; it requires less air for its combustion. Therefore the weighting of the float is more desirable with alcohol than with benzol, although its specific gravity is lower. The Pallas Carbureter Company says: "Our carbureters work without any change equally well with gasoline and with benzol." But it furnishes carbureters intended for alcohol fuel with a float weight which is soldered on.

After investigating the influence of air cocks and float weights on the steep road to Hohe Wurzel, I returned to comparative tests of different benzol-alcohol mixtures, and the results of these are shown in Table 10.

All runs of Table 10 began at kilometer-stone 5.5 and were made with full power. As seen from the first column of figures, the first three runs were made on July 3 with a mixture of 1 to 5, and the half-liter was used up at kilometer-stones 6.51, 6.49 and 6.49 respectively. On July 9 the same mixture reached in the first run only to roadstone 6.3, as the motor worked so poorly, owing to unusually cold weather, that a portion of the distance had to be covered on low gear. The figures of this table reveal a few small irregularities, as, for example, that on July 9 the 1 to 4 mixture worked less well than the 1 to 5 mixture. These irregularities are not due to any effect of wind resistance, as in the case of Tables 1, 2 and 3, but depend on whether the runs were made between 2 and 3 o'clock in strong sunshine on the steep hillside or under other conditions. At that hour the sun stood just in the direction of the main stretch of this very broad road, while at other times the road was shaded by the adjacent forests. Table 10 shows also a great difference in the two runs which were made on July 9 with a 1 to 2 mixture, one of these runs being made on second and the other on third gear. It has been ascertained by comparison with other subsequent trial runs that the difference in the present instance became so large only because the motor with a 1 to 2 mixture and on second gear reached an enormously high speed and could not be throttled on account of the purpose of working with full power.

The table further accounts for two runs with unmixed gasoline, which I have kept for extraordinary occasions since before the war, and a run with a mixture of benzol and kerosene has been added for comparison. I expect to report later on some additional trials with different benzol-kerosene-alcohol mixtures.

When average values are computed from Table 10, the figures listed in Table 11 are obtained. The showing for the mixtures which are rich in alcohol are here considerably less favorable than in Table 3. The reason lies in the shortcomings of these mixtures under heavy motor load—the same as noticed at point *C* in Table 2. This shortcoming can however be met with excellent results by narrowing the carbureter channel, as later trials have shown which will be included in my next report.

Table 10

HILL-CLIMBING TRIAL RUNS WITH ⅓ LITER OF FUEL AND HIGHEST SPEED. FIGURES REPRESENT KILOMETER-STONES REACHED, STARTING FROM STONE 5.5. HEAVY FIGURES INDICATE THAT SECOND GEAR — AND IN ONE CASE LOW GEAR — WAS USED

Fuel	*July* 3	*July* 6	*July* 9
1 benzol + 5 alcohol.....	**6.51**	....	**6.3**
	6.49	....	**6.5**
	6.49	....	**6.53**
1 benzol + 4 alcohol.....	....	**6.62**	**6.52**
	....	**6.57**	....
	....	**6.5**	....
1 benzol + 3 alcohol.....	6.75	6.72	**6.54**
	....	6.68	....
1 benzol + 2 alcohol.....	6.82	6.8	**6.59**
	6.83	....	6.83
1 benzol + 1 alcohol.....	6.84	6.83	6.86
	6.85	....	....
Pure benzol	6.89	6.87	6.9
	6.9	....	....
Pure gasoline	....	6.75	6.76
1 benzol + 2(?) kerosene.....	....	....	6.83

Table 11

AVERAGE VALUES IN METERS COMPUTED FROM TABLE 10

1 benzol + 5 alcohol.....	5.5 to 6.5	= 1000 meters
1 " + 4 "	" " 6.6	= 1100 "
1 " + 3 "	" " 6.7	= 1200 "
1 " + 2 "	" " 6.8	= 1300 "
1 " + 1 "	" " 6.85	= 1350 "
Benzol pure	" " 6.9	= 1400 "
Gasoline pure	" " 6.75	= 1250 "
Benzol-kerosene	" " 6.8	= 1300 "

[Von Loew here adds a table showing how far 1 mark's worth of each of the fuels and fuel mixtures will take a car at the present German fuel prices, which are 38 pfennig per liter for gasoline, 37.5 for benzol, 34 for denatured alcohol and the mixtures according to their proportions, but this table is here omitted as the prices during the war are artificial. As they are, the greatest mileage and therefore the greatest economy are credited to the equal mixture of benzol and alcohol, while unmixed alcohol is fully as economical as gasoline if the carbureter channel is narrowed, as above referred to.]

One defect attaches of course to all the figures in all the tables; namely, that they were all obtained with one car. I have, to be sure, also made trial runs with both my older cars, using benzol-alcohol mixtures up to the proportion of 1 to 2 with good success. But I have not taken note of numerical values with them, as little troubles easily arise with cars of the older types. When a spark plug misses fire even only for a few moments during a trial run, or a carbureter float sticks, the run is of course numerically without value. With the new cars these interruptions have so far not occurred; only once, on a trial run with solutions of naphthalene, some peculiar phenomena were observed which probably should be ascribed to crystalline precipitations of the naphthalene in the auxiliary jet.

[Translated from *Automobil-Rundschau*, September, 1915]

Stewart Adds Ford Starter

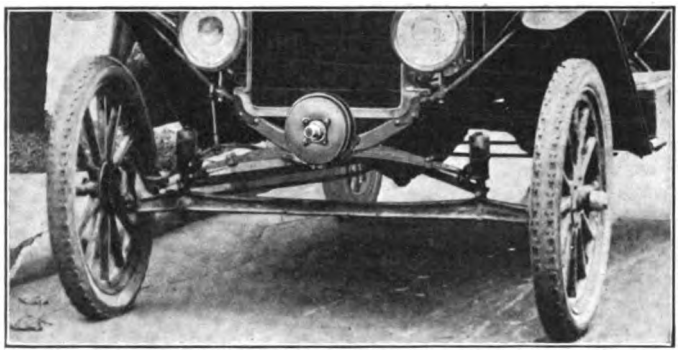
Is of Pneumatic Type, Combining Tire Pump—No Machine Work Necessary in Installation—Outfit $40

A PNEUMATIC starter designed specially for quick installation on the Ford car is the latest addition to the line of the Stewart-Warner Speedometer Corp., Chicago, Ill. The outfit consists of an air compressor, similar in design to the Stewart tire pump with modifications made necessary by the necessity of storing compressed air, an air motor having a rotating piston, a tank for the storage of the air under pressure, and lastly an automatic distributing or regulating valve and an automatic starting clutch. In addition to this the only two parts are the pedal push button with its linkages to the regulating valve and the sliding clutch, and a pressure gage on the dash, and the hose and pipe connection for the transfer of the air.

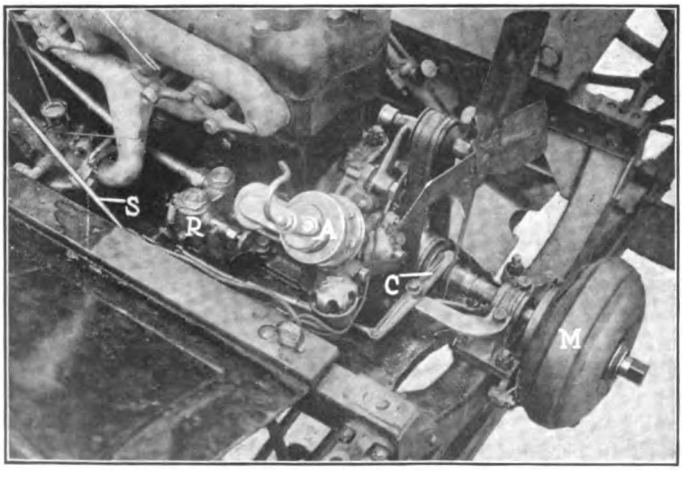
No Machine Work Necessary

The outfit ready for installation, which requires no machine work and can be done by any owner in a few hours' time, sells for $40. The starting motor, or cranking unit, is an air-tight cylinder, circular in form and which replaces the old crank handle. Passing through this cylinder is a shaft which engages the motor shaft, the same as the crank-handle shaft formerly did. Within the cylinder is a stationary head or vane *V*, also a piston *P*, or bat-wing valve, which is attached to the shaft. This valve or piston is attached to a collar through which the starter shaft passes, and inside of the collar is a pawl which engages the groove or teeth in the starter shaft. A driving clutch *C* is attached to the end of the starting shaft, the driven member being installed on the end of the motor shaft.

Stewart air motor with cover plate removed, showing rotating piston P and stationary vane V



How the Stewart pneumatic starter appears on a Ford car



Stewart air starter for Fords. S is control rod from floorboard, R regulating valve, A air compressor, C sliding clutch, and M air motor

In operation the driving clutch engages with the driven clutch at the same instant that a charge of air enters the starter cylinder. This air pressure causes the piston and shaft to make one complete revolution, but it spins the motor shaft up to as many as eight or ten revolutions.

In order to make a steady yet easy installation of the air pump, or compressor, it is an integral part of a timing gear case cover which is substituted for the cover already on the motor. The piston of the air pump is driven from an eccentric installed on the end of the timing gear shaft, and is running at half the engine speed whenever the motor is running. The air pump is designed to maintain pressure of 200 lb. in the air reservoir. When this pressure is reached a diaphragm valve in the pump closes the air intake and prevents pressure rising above 200 lb. When air is used for starting, or inflating tires, thus reducing the pressure in the reservoir, the pressure on the cut-out diaphragm is relieved and the intake valve opens, permitting the pump to force air into the reservoir until the 200-lb. limit again is reached. Thus the pressure in the tank is automatically maintained.

Tested for 600 Lb. Pressure

This tank, or air reservoir, is suspended underneath the body of the car and is carried in brackets which are attached to the frame. It is tested for 600 lb. per square inch pressure, so that the factor of safety is adequate.

The passage of air from the reservoir to the starter motor is controlled by the pedal through an outlet valve which is a part of the air control, or regulating valve. Pressing the pedal opens this outlet valve and permits a charge of compressed air to enter and operate the starter motor.

The outlet valve, which is operated by the pedal, also is connected with a lever which engages the driving clutch with the driven member, thus connecting the starter motor with the crankshaft of the car. There are two stages in the operation resulting from a pressure on the pedal. During the early part of the movement of the pedal the clutch is engaged in just the same way that the old hand starter crank is engaged with the shaft before the actual cranking is started. When the clutch is engaged further movement of the pedal opens the outlet valve, admitting compressed air from the tank to the starter motor, which spins the crankshaft.

For Winter Starting

For winter starting, the choker wire, normally connected with the carbureter and passing through the radiator, is replaced with a choker lever installed on the dash. Tire inflation is provided for by a valve and nipple on the air-controlled valve, and hose connection with tire pressure gage. The starter complete, with pump, tank, motor and connections, adds 42 lb. to the weight of the car.

Wanted! Racing Cars

THE racing year which has just closed with the Sheepshead Bay contest for the Astor Cup has concluded a series of demonstrations that the speedway event can become a part of our national life; that it is a popular sport and as a business, well worth following. But if it is to continue to be successful and popular we need, in fact we *must have*, some more cars. Even this year, despite foreign importations, we have not had enough cars of the first rank, and there has been but one big event to each speedway.

We have seen good racing from four teams. the Peugeots, Stutz, Duesenberg and Maxwell. What have we had outside these capable of sustained speed at meeting after meeting? Now it would appear that the Peugeots are tiring, just as a racehorse will tire and go stale after a few big contests. De Palma's Mercedes is giving such trouble that he and it have disappointed the public who had paid their money partly to see this combination on more than one occasion. What have we got left as next year's prospect?

A car of the first rank of speed is fit for only two or three hard, long races, especially a car that is far from its parent factory. American built machines have the advantage over the invader that they have their factory permanently behind them, and it is a matter of days only to get new parts or to try new schemes of detail design. Europe can send us no more cars to race with, and those we have will slowly but surely get worse and worse. Look at the performance of the Delage cars on the speedways this year and contrast it with their form two years ago.

Whatever help our big-minded manufacturers are able to give to owners of foreign cars in the way of factory facilities, whatever resources they have in repair shops and depot stocks are as nothing beside the advantage of a factory of origin close at hand.

We want five or six teams of three or four cars each from the leading factories of America. If the makers do not care to race, then let them build cars for sale to the many private sportsmen who have hitherto bought foreign productions. There are plenty of buyers for the proper class of car, and the prices paid in the past for alien machines were big enough to tempt the American manufacturer to consider the affair as a business proposition.

Here we have a great and prosperous business in the speedways, which have given pleasure to hundreds of thousands of spectators, and we have a far greater and far more prosperous industry in the automobile manufacturing field. Surely the greatest automobile producing country in the world can profitably care for the building of a few dozen racing cars a year. The foolish old idea that a manufacturer stands to lose by racing ought to be fairly well exploded now. The most ignorant man knows that the racing car and the passenger machine are as far apart as the racehorse and the mule. If a manufacturer does well in racing it advertises his name and is an advantage, but a firm with an established name in the touring car field would never miss an order by reason of failing in a race or two.

Any first-class factory can build a fairly good racing car, so widely has the knowledge of the principles and practice been spread, and so many are the existing good machines for study. A car of good material and sound design may not be a world-beater, but it could not fail to make a good showing and to provide good racing anywhere. Mere *presence* in the racing field is a sign that the organization is alive and progressive. It shows that the engineering force behind the touring car of standard production are men of intellect and experience, and, moreover, the knowledge to be gained, that is of value in everyday work, is much more than anyone could guess without actual trial.

America, thanks to the efforts of just two or three firms, is in a position in the racing world which it is worth while holding for the sake of our trade abroad. It is up to our manufacturers to realize that there is no market for American automobiles where the speeds made in the last few races here will not have an effect in raising the reputation of "made in U. S. A."

Furthermore, automobile racing when it is safe and sane and well conducted, as it is on our great speedways, is a magnificent advertisement for the motor car and motor-car using. The races without doubt have a potent effect in selling automobiles of all grades. So from the wide outlook of the whole industry the speedways are worthy of a proper support, a support that manufacturers should be quick to give.

Couzens Resigns from Ford Co.

Organizer of Great Business Finds Ford's Peace Propaganda Unendurable

DETROIT, MICH., Oct. 12—James Couzens, vice-president, treasurer and general manager of the Ford Motor Co., and who has been generally recognized as the great force back of the business end of the organization, resigned to-day from all active connection with the Ford organization, the reason given being that he could not agree with the recent public utterances of Henry Ford on the national question of peace and unpreparedness. Mr. Couzens' resignation comes as a sequel to the division between Henry Ford and the Dodge Brothers, which resulted in the starting of the Dodge factory over a year ago. It has been understood that there have been differences between Couzens and Ford for several years, these differences dating to some time before the Ford announcement of his profit-sharing plans, and also before the break with the Dodge Brothers. It is claimed that the split, however, is a direct result of the use of the Ford Motor Co.'s publication, the *Ford Times*, for the expression of Mr. Ford's views on war and preparedness.

Mr. Couzens' connection with Henry Ford dates back to the early part of 1902 when he first met Ford and became interested in the building of a sample car. Couzens, Ford and another associate followed the development of this particular sample, or experimental car until the spring of 1903 when they set about to form the present Ford Motor Co., which was organized in June of that year, and Mr. Couzens became business manager and secretary.

Couzens the Organizer

In the Ford organization it has always been recognized that Henry Ford was the man who was responsible for the early cars of 1902, as well as practically all models and designs of the company since, but that James Couzens has been the organizing, business, and financial moving spirit of the concern. The extent to which Mr. Couzens has profited from the Ford organization is practically indicated last June when the directors of the company increased the capital stock from $2,000,000 to $100,000,000, and when it was announced that Mr. Couzens received 1¼ per cent. At that time when the $48,000,000 new stock was distributed among the eight stockholders as a dividend, Mr. Couzens share was $4,800,000.

In speaking of his separation with Mr. Ford, Mr. Couzens said:

"I disapprove of Mr. Ford's views on preparedness, which proved of such serious moment to me that I was compelled to rupture my business relations with him. The friendly relationships between us that have exisited for twenty-two years have been changed of late, our daily differences increasing."

Although no definite information can be gained yet as to the changes to be effected in the Ford organization due to the resignation of James Couzens, it is stated on good authority that no one man will step into the position left vacant. Undoubtedly Frank L. Klingensmith, present secretary of the company will receive promotion, although Henry Ford states that several men will be advanced in order that each can take a part of the work. Ford states that the reorganization will be entirely among the present officials, the policy being to develop the concern's own men rather than seek department heads from outside. Among the men who will undoubtedly share in the change is C. H. Wills, the present production manager, who has been materially responsible for the great developments of the company, and Sales Manager N. A. Hawkins.

—

Hudson to Concentrate on Six-Cylinder Types

DETROIT, MICH., Oct. 11—Rumors that the Hudson Motor Car Co. intended to bring out a twelve-cylinder motor have been heard many times during the last few months. There was even talk about a Hudson eight. To set everybody at rest, the Hudson company has now made a definite announcement to the effect that it will confine all its energy to the Hudson six, believing this to be the best motor.

In its announcement the company says: "The refinement and development of the six-cylinder type of motor leads us to believe that it surpasses in simplicity, low cost of upkeep, performance and general adaptability any other type of motor so far developed for use in pleasure vehicles."

—

Michelin Brings Out Non-Skid

NEW YORK CITY, Oct. 9—The Michelin Tire Co., Milltown, N. J., has brought out a non-skid tire with rubber elevations which is known as the Michelin Universal tread. This is the first time this concern has manufactured a rubber non-skid tire. It has the flat tread of the Michelin racing tire, and on the tread is a raised pattern consisting of the letter M in a continuous series; the interstices between the rows of letters form a suction against the road and tend to hold the tire from slipping.

Sizes and prices of the new tire are:

32 x 4	$22.00	35 x 4½	$30.00
33 x 4	22.50	36 x 4½	30.75
34 x 4	23.00	37 x 4½	31.50
36 x 4	24.75	37 x 5	36.25

56 In. To Be Standard Tread

N. A. C. C. Directors Vote for Uniformity in This Respect, Beginning July 31, 1916

NEW YORK CITY, Oct. 7—At the meeting of the board of directors of the National Automobile Chamber of Commerce, Inc., held here it was decided to standardize the treads in motor vehicles at 56 in. after July 31, 1916. This will bring into line many vehicles which heretofore only varied from the given measurement by a fraction of an inch. A large majority of cars now in use has the 56-in. tread. The Chamber will hold its usual banquet during show week.

The traffic department's report indicated continued record shipments of motors cars. This has resulted in a shortage of freight cars, but the makers are co-operating with the railroad companies to avoid any serious delay in shipments.

Regarding the deliberations leading up to the adoption of the 56-in. tread, the committee on treads met in Detroit not long ago and prepared its recommendations. The trade had been broadly canvassed with the idea of securing the viewpoints of the manufacturers and the result was that it was decided to drop the practice of making 60-in. tread for the Southern trade. It was discovered that only in very few sections of the country were the roads in such a condition that the 56-in. tread offered any difficulty and the result was that they have all agreed to the 56-in. standard. One of the difficulties said to be in the way of the 60-in. tread is that the manufacturers concentrate their minds on the 56-in. standard with a result that orders for 60-in. tread are side-tracked until the factories are under less pressure.

—

Collins and Hibbard Resign from R-C-H

DETROIT, MICH., Oct. 11—After having been connected with the re-organized R-C-H Corp. since February, 1914, A. H. Collins, vice-president and assistant general manager, and V. S. Hibbard, sales and advertising manager, have resigned. No successors have been named. Messrs. Collins and Hibbard will shortly announce their connection with a new concern now in course of organization.

—

Hood Visits Detroiter Dealers

DETROIT, MICH., Oct. 11—Wallace C. Hood, general sales manager of the Detroiter Motor Car Co., is on an extensive trip through Illinois, Minnesota, Iowa, Wisconsin and Missouri, where he will visit Detroiter dealers and distributors.

August Exports Are $9,567,348

Over $2,000,000 Less Than in July—Cars Lower and Trucks Higher

	August, 1914 No.	Value		August, 1915 No.	Value
Cars	385	$441,879	Cars	3839	$3,121,834
Trucks	68	124,016	Trucks	1614	4,387,193
Parts	...	196,527	Parts	....	2,038,321
Total		.....$562,422	Total		....$9,567,348

WASHINGTON, D. C., Oct. 11—Exports of passenger cars and trucks together with parts, during August last amounted to $9,567,348, as compared with $562,422 for August, 1914, and with $12,302,345 in July last. Passenger car exports in August, 1915, were lower than the previous month, the August figures being 3839 cars valued at $3,121,834, compared with 2469 cars valued at $6,803,001 in July, 1915. During August, 1915, 385 cars valued at $441,879 were exported. Trucks numbering 1614 and valued at $4,387,193 were exported in August, as compared with 4118 valued at $3,835,347 in July last. Truck exports during August, 1914, numbered only sixty-six, valued at $124,016. Parts exports during last August, amounted to $2,038,321 as compared with $1,663,997 in July last and with $196,527 in August, 1914.

—

Continental to Increase Capital

DETROIT, MICH., Oct. 12—A special meeting of the stockholders of the Continental Motor Mfg. Co. has been called for Oct. 19, the purpose being to propose an increase of the capital stock of the company in order to declare a stock dividend. While officers of the Continental company are not willing to make any statement as to this dividend, it is rumored that it will be of 100 per cent.

The present capitalization of the company is $1,500,000. Its fiscal year ends June 30. At the end of the 1914 fiscal year the company had a surplus of $754,227.51. Its assets and liabilities totaled $3,075,388.97. The paid par value of its stock is $100. During the last two weeks it has gained more than 40 points on the local stock exchange. The business of the company is said to be between 25 and 40 per cent larger at this time than it was at the same period in 1914.

—

Perfection Spring Raises Capital

CLEVELAND, OHIO, Oct. 11—The Perfection Spring Co., this city, will increase its capital stock, now consisting of $500,000 7 per cent cumulative preferred and $1,000,000 common to $1,000,000 7 per cent cumulative preferred and $1,500,000 common. Of the new issue there will be issued at this time up to $250,000 preferred and $1,000,000 common, but no offering will be made to the public at this time.

Application has been made to the secretary of state at Columbus, for a charter for the Perfection Spring Co. of Cleveland with the above new capital. The company will take over the assets and business of the present company of that name.

The directors of the new company are: F. F. Prentiss, C. C. Bolton, T. E. Borton and Attorneys Horace Andrews and Benjamin Gage. This is a temporary organization. The permanent board will be elected later.

—

Zimmerschied Talks Metallurgy Before Detroit S. A. E.

DETROIT, MICH., Oct. 12—Before 200 members of the Detroit section of the Society of Automobile Engineers and guests, K. W. Zimmerschied, chairman of the Standards Committee, gave a talk here to-night on the Influence of Metallurgy on Design. The question always has been, he said, whether a part should be large or of better material and smaller in section. There are limits to the development in reducing of size by the use of better materials and great progress has been made in the last five years regarding the cause of steel failures.

Zimmerschied touched upon the mechanism of failure and dealt with the theories of molecular and crystalline structure of steels. He advised the avoidance of sharp corners or abrupt changes in section of parts, as they localize stresses. He refers to sharp edges in keyways, splines, etc. Scratches and tool wounds also have this effect. Vibrational stresses are also to be guarded against.

A very interesting series of moving pictures illustrating the evolution of steel pipe from ore to finished product was shown by the National Tube Co.

—

Naval Engineers to Attend Metropolitan Section Meeting

NEW YORK CITY, Oct. 13—Twenty naval engineers who are studying this year at Columbia University are expected to be in attendance at the meeting of the Metropolitan Section of the Society of Automobile Engineers, Oct. 21. The papers are of broad interest and should attract considerable attention. Prof. William Campbell of Columbia University, who is a widely recognized authority on metallurgy, will deliver a short address on the elements of metallography and this will be followed by a series of motion pictures showing the manufacture of steel tubing from ore to tube, with a lecture on the processes of manufacture.

France to Have 45% Duty

Plans to Secure Russian Market For Entente Powers, Excluding Neutrals

PARIS, Sept. 24—American automobiles entering France are to be met with a 45 per cent tariff. This information is given on the very highest authority. Negotiations are already well in hand between the united body of French automobile manufacturers and the Government which will lead to a complete revision of the tariff. Before England had decided on a 33 1/3 per cent import duty, and while this move was unknown in France, it had been decided in France to raise a protective tax. Either the American tariff wall as regards automobiles must be cut down to the French level, or the French wall will go up to the American height. As rapid action may be expected in this matter as shown by England. The French industry, which has the full support of the Government, is determined that American manufacturers shall not step in and grab its markets during the after-the-war interval when the demand will be strong and the home factories will be unable to meet it.

Makers' Union Excludes Germany

There is a more important phase of this protective campaign. The various automobile manufacturers' associations of Europe are united in an international union. Germany is a member of that union, but she will be struck off, and will remain off, when the war comes to a close. France, England, Belgium and Italy, will remain the leading members of that union. Russia will not be in, for she has no automobile industry; she will be considered, however, on the same footing as the active members. By means of the union, reciprocal preferential tariffs will be established among the Allied nations and prohibitive tariffs erected against neutral and the present enemy nations. This means that the Russian automobile market will be open to England, France, Italy, and Belgium, but will be protected against other countries by high tariffs. The Russian market is the most important, for it offers infinite opportunities of development. What applies to Russia is applicable to the other Allied nations. France, England, Italy and Russia do not fear one another's competition. France and England are fully aware that the war will find their automobile factories swept clean of both automobiles and automobile parts and faced with a transition period during which they must transform their works from war to peace requirements.

Indianapolis Race to Be 300 Miles

Next Speedway Contest on Hoosier Track May Be for $30,000 Instead of $50,000

INDIANAPOLIS, IND., Oct. 8—Carl Fisher, president of the Indianapolis Motor Speedway has announced, this week, that the next Speedway race slated for the Indianapolis speedway would be 300 miles instead of 500, as has been the custom heretofore.

"I am convinced that the shorter race will be more popular with the race going public, for experience has taught us that 500 miles is a little too long to be enjoyed fully by the spectators," said Mr. Fisher.

Mr. Fisher said that he believed all contests next year would be 300 miles and that purses would be reduced accordingly to $30,000 instead of $50,000. When asked if the race May 30 would be for $30,000 instead of $50,000, Mr. Fisher said that he would be in a position later to make a statement on this angle of the race. He left the impression, however, with his auditors that the purse would be $30,000.

—

Predicts Lower Gasoline Prices

PHILADELPHIA, PA., Oct. 11—Speaking before the Franklin Institute of this city Dr. Benjamin T. Brooks, in charge of petroleum research in the Mellon Institute of Industrial Research at Pittsburgh, predicted that the price of gasoline would in the future be lower by reason of the methods which are being found for its extraction from the heavy crude oils. In his subject, The Decomposition of Petroleum Hydrocarbons by Heat and Its Application to the Motor Fuel Problem, Dr. Brooks pointed out that the automobile industry had increased out of proportion to the gasoline supply of the country. He had among his hearers chemists, engineers, oil and gasoline experts, and automobile owners.

—

German Control of Benzol Ends

NEW YORK CITY, Oct. 9—The prediction was made last night at the first fall meeting of the local section of the American Chemical Society at the Chemists' Club, 50 East Forty-first Street, that at the end of the European war benzol would find extensive use as a substitute for gasoline as the motive power for automobiles. It was pointed out that whereas before the European war this country was producing only 3,000,000 gal. of benzol, the large steel works, many of which did not recover their benzol, are now producing about 15,000,000 gal.

It was also predicted that the German domination in this product, existing before the war, will probably be a thing of the past.

I. F. Stone, president of the National Aniline & Chemical Co., and speaker of the evening, stated that benzol could be produced now and sold at the same price as gasoline if it were necessary to do so. It is being largely used in Europe in place of gasoline, and the only reason it has not been used here has been the limited production and the high price, it normailly being about double the cost of gasoline.

Careful experiments for automobile purposes show that benzol has a motive power about 25 per cent greater than gasoline.

—

To Build More Gasoline Plants in Texas

DALLAS, TEX., Oct. 8—Several plants for the manufacture of gasoline from natural gas will be built in Texas within the next few months, according to the statement of James Howard, the representative of one of the companies that is preparing to engage in the industry. It is stated that there are now about fifty plants in Oklahoma that manufacture gasoline from what is known as casinghead gas, or that gas which comes direct from the well with crude oil. The total output of these Oklahoma plants is about 80,000 gal. of gasoline daily. They are located at Tulsa, Bartlesville and other points and are being constantly increased in number. The gas which is now utilized for the manufacture of gasoline was formerly a waste product. In California there are said to be about twenty plants of this kind and they have a total daily capacity of about 35,000 gal. Some gas runs higher in gasoline than others. It takes about 500 cu. ft. of gas to yield 1 gal. of gasoline.

The grade of gasoline that is obtained from natural gas is more volatile than that which is obtained from crude oil. It grades all the way from 75 to 90 deg. gravity, and it is then reduced to a gravity of about 60 deg. by treating it with naphtha.

—

Independent Gasoline Companies Meet in Chicago

CHICAGO, ILL., Oct. 9—Western independent oil jobbers are meeting here to appropriate funds for prosecution of independent refiners who, they say, are in subterranean agreement with the Standard Oil Co. to hold up gasoline prices.

—

Twin City Gasoline Higher

MINNEAPOLIS, MINN., Oct. 9—The price of gasoline in the Twin Cities has advanced to 12½ cents, following a recent advance of 1 cent to 11½ cents per gallon.

100-Mile Race for Sheepshead

Tentative Plans Outlined for Special Race of Leading Drivers—$12,000 Prizes

NEW YORK CITY, Oct. 12—Tentative plans have been outlined for a special race on the Sheepshead Bay Speedway here Election Day, Nov. 2, at which probably six of the leading winning drivers of the year will compete. It is purposed to have $12,000 in prizes. $1,000 will be given as a guarantee of expenses to each of the six cars entering. The $6,000 remaining will be divided between two races, one of 50 miles with $2,000 in prizes and the second race of 100 miles with $4,000 in prizes. Harry Stutz has announced that none of his cars will be in the contest although there is a possibility that Cooper or Anderson may drive other makes. The drivers assured are Resta, Rickenbacher, Aitken, Oldfield, Burman, and perhaps Anderson or Mulford. It seems probable, however, that few if any of the winning cars will be available.

—

New York Gasoline Up to 23 Cents a Gallon

NEW YORK CITY, Oct. 11—The price of S. O. gasoline in this city has been raised to 23 cents a gallon retail. This is the third advance in the last three days. Refiners on Thursday sent out notice of an advance in the wholesale price to 17 cents per gallon, making the fourth advance in price in the past three months. Retailers were selling at 21 cents on Thursday. On Friday the price went up to 22 cents, and on Saturday still another cent. Other oils, excepting kerosene, were advanced in sympathy with gasoline.

The dealers ascribe the advance to the enormous demand made upon American refiners by the European war and the largely increased consumption at home. Most of the companies suffered severely by the recent storms in the South. The producing facilities of several of them have been so crippled that they were obliged to buy from competing companies at a sacrifice in order to meet the demands of their trade.

—

Velie Adds Four-Passenger Coupé

MOLINE, ILL., Oct. 8—The Velie Motor Vehicle Co., this city, has added a new body to its line mounted on the model 22 six-cylinder chassis. It is a four-passenger coupé with the driver's seat mounted slightly ahead of the passengers' seat which has a capacity of two. The seat for the fourth seat is mounted on a stationary pedestal capable of being

revolved in any direction. This provides a large, roomy car and there are drop windows which can be opened in seasonable weather. The car sells for $1,750, trimmed in dark blue whipcord.

The Velie 22 chassis has a 3½ by 5 block power plant, 124-in. wheelbase, 34 by 4 front tires and 35 by 5½ rear, dry plate clutch, four-speed gearset and is fitted with Gray & Davis electric lighting and starting.

—

Jones Motor Car Co. Formed with $500,000 Capital

WICHITA, KAN., Oct. 9—A charter incorporating and authorizing a capital stock of $500,000 for the Jones Motor Car Co., this city, to manufacture the Jones Six, has been granted. Of the entire capital stock, $200,000 is taken by J. J. Jones, founder of the company, which began less than a year ago to build cars in a local plant here. The Jones six sells for $995.

With the granting of a charter, a reorganization in the local company takes place. Mr. Jones turns over the plant which he owned privately to the new company. But two Wichita men are named as incorporators, they being Mr. Jones and J. W. O'Neill, former treasurer, Kansas Casualty & Surety Co.

W. A. King, for fourteen years connected with the Detroit plants, will take charge of the local shops as chief engineer and superintendent of production.

—

New All-Year Car for Mitchell

NEW YORK CITY, Oct. 9—The Mitchell-Lewis Motor Co., Racine, Wis., has brought out a new demountable Sedan top selling for $165 and furnished on both the five- and seven-passenger models. The interior is lined with whipcord and a large electric light is concealed in the top of the car. The windshield is built-in with ventilating features. The side windows are removable.

—

Lynch, Hollier Production Manager

JACKSON, MICH., Oct. 9—The Lewis Spring & Axle Co. has appointed Leight Lynch production manager. Mr. Lynch was formerly a member of the Studebaker Corp.'s organization and more recently general manager of the American Top Co., Jackson.

—

Pfeffer Off for Coast

DETROIT, MICH., Oct. 12—Vice-president and assistant general manager C. A. Pfeffer, of the Chalmers Motor Co., is en route for the Pacific Coast, to call upon Chalmers dealers and distributors. He will make stops at Chicago, Los Angeles, San Francisco, Portland, Seattle, Salt Lake City, Denver, Kansas City and several other important distributing places.

Perrin Is Timken Axle Engineer

—

Alden Continues as Vice-President—Baldwin Service Manager—Other Changes

DETROIT, MICH., Oct. 8—J. G. Perrin has joined the Timken-Detroit Axle Co.'s organization in the capacity of chief engineer. Mr. Perrin was the designer of the first Lozier automobile and remained as chief engineer of the old Lozier Motor Car Co. for nineteen years. Last March he became a consulting engineer for the Continental Motor Mfg. Co. He has specialized on axle and chassis construction and is a member of the standards committee of the Society of Automobile Engineers, and also of the Detroit section of that organization.

H. W. Alden, who was chief engineer and vice-president of the Timken company, remains as vice-president.

G. O. Baldwin has been appointed service manager of the company. He formerly held a similar position with the Cadillac Motor Car Co., also with the Studebaker Corp.

J. M. Ready, formerly assistant to Leslie Williams, manager of accounts of the Timken-Detroit Axle Co., Clark Avenue plant, has been changed to the Timken-Detroit Axle Co.'s Metal Products plant, on the East side of Detroit.

F. H. Maisonville has been appointed assistant to W. H. H. Hutton, Jr., director of purchasing. He was formerly assisting purchasing agent with the Packard Motor Car Co.

—

Materials Only Handicap of Detroit Factories

DETROIT, MICH., Oct. 12—The factories here continue to turn out cars in as large quantities as they are capable of, due to a demand which seems insatiable. Here and there curtailment of output is noticeable but this is not chargeable to lack of orders, but solely to inability to get the parts and raw materials necessary.

Although in some quarters it has been predicted that there would be improvement in the materials market, no such betterment of conditions has yet made itself evident, and the situation is causing no end of worry all along the line. Concrete evidence of the scarcity of certain standard forms of raw stock is easy to find. At one carbureter factory where they were formerly making float counterweights out of brass stock already rolled into circular form, they have been obliged to turn the pieces out of solid square stock. This is just an instance of what the shortage has meant and does mean. In many instances the inability to get the kind of material required has forced the working out of new methods of manufacture of certain parts.

Those concerns which did not have contracts placed months ago for their present requirements are the worst sufferers. Where foresight and money have made it possible, the slowness of parts delivery is not felt as badly as in cases where a concern's output is small, and it was impossible for it to tie up large sums in parts which were not to be used for several months later.

—

Chalmers Shipments Gain 302%

DETROIT, MICH., Oct. 9—Shipments of the Chalmers Motor Co. for the quarter ended Sept. 30 showed a gain of 302 per cent over the same period of 1914. The company sold 154 more cars in July, August and September this year than were sold in the first nine months of the fiscal period ended June 30 last.

—

1-Ton and 2-Ton Superior Trucks to Be Built in Atlanta

ATLANTA, GA., Oct. 8—E. G. Willingham's Sons, this city, will build the Superior truck in this city, as announced in THE AUTOMOBILE for Oct. 7. G. E. Whiteside, formerly with the E. R. Thomas Motor Co., LaSalle Niagara Auto Co. and the American Locomotive Co., is chief engineer. One and 2-ton type trucks will be built.

The truck is equipped with three-point suspension, valve-in-head motor, with offset crankshaft, multiple disk, Raybestos faced clutch and a unit power plant driving to internal gear-driven rear axle.

The rear axle construction is a feature. The drive is in the rear and does driving duty alone, as the load is carried on a solid I-beam member.

The company expects to make deliveries on its 1-ton truck, costing $1,350, by Nov. 1. An express body will cost $50 additional.

—

Plan Climb to Pike's Peak

DENVER, COL., Oct. 8—The Pike's Peak Highway Association is planning to hold a hill climb next year over the 17 miles of road from Cascade to the top of Pike's Peak. One feature of the program, which will cover several days of competition, according to present plans, will be a truck contest, a result of the climb to the peak by the Wilson truck at the time of the highway opening.

—

Parish & Bingham Buy Land

CLEVELAND, OHIO, Oct. 11—The Parish & Bingham Co. contemplates increasing its plant at West 106th Street and Madison Avenue, N. W., by 10 acres. A 10-acre tract at West 106th Street and Madison Avenue has been bought. The plant of the company covers a ground space of 22 acres.

Australia with Record Crops To Be a Leading Automobile Buying Power

American Automobile Manufacturers Benefited by Stoppage of European Exports to that Country—Majority of Cars Use American Tires—N. S. W. Imports Lower

SYDNEY, AUSTRALIA, Aug. 20—Australia, as an automobile buying power, promises to be a leader. Trade conditions throughout the whole of that country are at present very good, considering the expense the country is now undergoing on account of the war.

In Victoria, South Australia and Western Australia, the farmers will enjoy one of the finest and most prosperous seasons. The visible wheat at the present time constitutes a record crop.

The rise in value of the pound sterling in that country, which is at present well over par, means that the farmers will be able to clear off all debts on their holdings and will be in the fortunate position of having plenty of money.

Much difficulty during the first six months of 1915 was experienced with freight, many houses having much stock lying for four and five months on the wharves, especially in San Francisco. The effect of this was to throw trade into a state of confusion. This was offset, however, on account of a number of houses being stocked with last year's models, through the effects of the war, and business kept on going in a fairly prosperous manner. The present outlook of freight conditions is not very promising.

The stoppage of European vehicles being sent to this country has especially benefited the American makers. American trucks are fast finding a market and the outlook for large sales is very promising.

There are one or two things the truck makers will have to watch closely, and one is that all vehicles will have to be right drive. The position of the gear levers in the center does not matter a great deal as far as trucks are concerned.

New Truck Agencies

A number of the truck makers are taking advantage of the present demand by establishing Australian agencies. The Jeffery Co. recently established agencies throughout the whole of the Commonwealth, and one of the largest catering firms in Australia is now using those trucks. The Kellys Motor Garage of Sydney has taken on the Federal and the Sanford. Larke, Hoskins & Co., Sydney, who have never handled American cars before, have taken on the Republic. Dalgety & Co., of Sydney, Melbourne and Perth, have added the Willys-Overland and the Anderson electric. Murray, Aunger & Co. of Adelaide, have also taken on the Willys-Overland. V. Lewis, Ltd., of Adelaide, has taken on the Signal truck. McIntosh & Sons, Ltd., Sydney, recently added the G. M. C. line of trucks.

The best agents in the Commonwealth are now representing the American trucks. There are a number of other agents, not doing quite the same bulk of business, still availble for agencies.

In the passenger car field, the Ford leads in prosperity with Overland and Buick next. The Studebaker car is also doing a good business. The Hupmobile is doing well with the firm of Evers Bros. in Brisbane, and also with Denys, Lascelles of Melbourne, and Phizackerleys of Sydney. Another newcomer on the market is the Pullman, which has been established throughout all the capitals in the hands of new agents.

50 Per Cent Tires American

More than 50 per cent of the cars are using American tires, as the importation of European tires is practically stopped. American tires are finding a large market. At the present time the Goodrich, Goodyear and U. S. tires are being handled in Australia.

N. S. W. Imports Drop

Imports during the first six months of 1915 into New South Wales, the leading automobile buying State in Australia, dropped 43 per cent under those of the same period in 1914. $927,550 in chassis, parts and bodies were imported into that State in the first half of 1915 as compared with $1,649,085 in the same period of 1914.

The United States led all the other countries with a total import on its chassis and bodies of $374,010 against $304,735 for the United Kingdom, its nearest competitor. The American im-

Tabulation of Car, Chassis and Parts Imports into Australia in the First Six Months of 1915 and 1914

FIRST SIX MONTHS, 1915

Italy	6,695		
U. S. A.	89,590		
Total	$276,035	Total	$276,035

ports, however, fell off considerably from those of 1914, which amounted to $621,620, over 39 per cent higher.

It will be noted by the accompanying table that quite a few of the American cars were sent either through Canada or England, probably on account of the poor freight conditions at San Francisco, from which place they could be sent direct.

Sales conditions in New South Wales may be reflected in the latest registration figures. During the first half of 1915, there were 1415 new cars registered. Commercial vehicles numbered 109 and motorcycles 1371. The total number of cars in use on June 30, 1915, was 10,570. The commercial vehicles numbered 639, taxicabs 236, and motorcycles 6461.

—

$7,054,897 in Imports to Canada During 1915 Fiscal Year

DETROIT, MICH., Oct. 9—During the fiscal year ending March 31, 1915, Canada imported automobiles and parts having a total value of $7,054,897. This is a drop of $4,124,857 from the 1914 record which showed imports to the value of $11,179,754. Canadian made automobiles and parts exported during the fiscal year show a total value of $2,954,453 or $853,266 less than in 1914 when the total was $3,807,719.

Of the total value of the imported cars and parts the United States is credited with $6,734,077 out of the total of $7,054,897 for the past fiscal year while during the 1914 fiscal year the total credited to the United States was $10,454,163 out of the total of $11,179,754.

The details as to the imports and exports are shown in the accompanying tables:

IMPORTS

AUTOMOBILES AND MOTOR VEHICLES

From United States	1915	$4,591,182
From United States	1914	6,528,086
From Great Britain	1915	252,898

To other countries	1915	243,070
To other countries	1914	197,621

Blaze Dixie Highway Trail

—

Many Cars in First Official Inspection Tour from Chicago to Florida

FRENCH LICK, IND., Oct. 11—*Special Telegram*—French Lick was the objective to-day, there being 120 miles of stone and gravel roads between Indianapolis and the Hoosier Spa. It was a corkscrew journey, the roads winding in and out among the hills, but the most delightful day of the tour so far.

The run to French Lick took the tourists through the most scenic section of Indiana, over rolling hills, past fertile fields picturesque with the weather-worn rail fences of our grandfathers.

The same enthusiasm over the Dixie Highway marked to-day's run as that of the two previous days. Groups of farmers gathered at the crossroads to watch the cars go by. Pupils of the district schools answered the screech of motor horns with yells of welcome. There were throngs of people in the village squares of the various towns to promise their support of the great project that is to make North and South better friends and neighbors.

Brass bands blared at Martinsville, Bedford, Orleans and Paoti, and many were welcome signs strung across the road. At Bloomington, the noon stop, the officials of the Dixie Highway Association were showered with flowers as the Miami bound cars passed down the Main Street, which for more than a mile, was lined on both sides by residents. The bugle and drum corps of Indiana University marched in front of the motorcade and played martial music.

Highway Officials Join Party

Before the start of the run, four more notables joined the party, Tom Taggart, feudal baron of the Indiana Democrocy and vice-president of the Dixie Highway Association; Carl G. Fisher; Charles Bookwalter, former Mayor of Indianapolis and speechmaker extraordinary, and Kin Hubbard, the Hoosier philosopher and cartoonist. The skill of the drivers was put to a test as well as the cooling and accelerating powers of the cars, for the grades on the trip were steep and gear shifting was imperative. The roads were fine, especially on the afternoon run from Bloomington, and very little work will be necessary on this link of the highway to put it in first class condition.

On the outskirts of Martinsville, a 2-mile stretch of brick road is partially completed and other improvements, including the elimination of several sinuous turns, will be made in the spring in that vicinity. Tuesday morning is to be a half day of rest and recuperation, a meeting the directors being scheduled at that time.

A ribbon of dust hung over the road that joins Chicago and Danville on Oct. 9, as the cars, participating in the first official inspection tour of the Dixie Highway, covered the first leg of the 1800-mile journey. The start was made from Chicago at 9 o'clock and the pilgrims reached Danville shortly before 6 o'clock.

Governor Edward F. Dunne of Illinois, was the guest of honor on the trip to Danville and, before the cars checked out of Chicago, dedicated the motor thoroughfare that is to link the Great Lakes to Florida. The dedication ceremonies were held in front of the Lorado Taft statue, at the south end of the Art Insitute.

The first 25 miles of the trip was over the Chicago boulevards and the improved roads that connect the Illinois Metropolis with Blue Island and Chicago Heights. The motorcade of more than 100 cars was given an ovation at both these points.

Good Dirt to Danville

After leaving Chicago Heights, fair dirt roads were encountered as far as Momence. Here the tourists ran into a whirlwind of dust through which they rode for 28 miles. When they reached Watseka, the noon control, they were so full of dust that they had no appetite for the luncheon tendered them by the Watseka Commercial Club. In fact, they relished the promises of the Watseka citizens that this stretch would be improved inside of another year, far more than the corn beef and cabbage that was set before them.

Watseka county, the seventh richest county in the United States, is planning to vote a $1,500,000 bond issue this spring and by this time next year, a ribbon of concrete will replace the sand and dust trail between Momence and Watseka. At least, this is the pledge that the residents of the county have made and they say that it will not be repudiated.

More dust, but better roads were encountered on the afternoon trip to Danville, a distance of 65 miles.

Dedicate New Road

Upon arriving at Danville, the Dixie Highway tourists participated in the dedication of a 3-mile stretch of brick road that has just been completed, and in the evening, a banquet was held at the Elk's Club where Governor Dunne and Joseph Cannon, former Speaker of the House of Representatives, were the principal speakers.

The following officials of the Dixie Highway Association were in the motorcade that left Chicago: Judge M. M. Allison of Chattanooga, president; M. E.

Temple and T. R. Preston of Chattanooga, directors; W. S. Gilbreath, field secretary; and V. D. L. Robinson, assistant secretary.

The cars that will make the entire trip, are Field Secretary Gilbreath's Franklin; the official Cole; President Allison's, Cadillac; W. M. Dilsaver's, Hudson; J. H. Friberg's, Hudson; the Standard Oil Co.'s Overland, and George Scarborough's, Chevrolet.

Crawfordsville Meets Pilgrims

Eleven miles outside of Crawfordsville, the noon stop on Oct. 10, more than 100 cars met the Dixie Highway pilgrims and escorted them into the city that boasts of being the birthplace of Lew Wallace, the author. Luncheon was served there, the members of the Crawfordsville Commercial Club and the Montgomery County Automobile Club being hosts.

Before entering Indianapolis, the tourists made a circuit of the Indianapolis motor speedway at the invitation of Carl G. Fisher, who will be a member of the inspection party when it leaves here for French Lick to-morrow morning.

A Change of Program

ELIZABETHTOWN, KY., Oct. 12—On the original schedule Louisville was the night stop of to-day's run, but at a meeting last night the directors decided to extend the tour to this place in order to reduce the mileage of Wednesday's trip to Nashville because of the poor roads that will be encountered. This revision necessitated an early getaway from French Lick. Good dirt roads were traveled all the way to-day with the exception of a 10-mile stretch late this afternoon, when the cars would have had trouble had the day been stormy instead of fair. On the morning run from French Lick to Louisville the grades were not as steep as those of yesterday although we were among the knobs of Indiana. The roads were of stone and gravel.

Michigan Joins Union

At a directors' meeting held at French Lick last night, Michigan was admitted into the union of eight States that have pledged themselves to make the Dixie Highway an improved road from Chicago to Miami. It is the intention of the Wolverines to build a loop around the State, extending north from South Bend through Niles and Kalamazoo to Mackinack and South via Detroit and Monroe to Toledo, Dayton and Cincinnati. P. T. Colgrove and Frank Hamilton were elected directors from Michigan. The directors also adopted the Dixie Highway marker, which is to be a blue bale of cotton on a white field with the words Dixie Highway, in red.

1,006,835 Ford Cars Built

—

Up to Oct. 1 the Combined Production of All Plants Reached That Total

DETROIT, MICH., Oct. 11—There are now a great many more than a mere million Ford cars in operation throughout the world. On the first day of October car No. 1,006,835 had been manufactured and sold. Thus the dream, as well as the hope, of Henry Ford, that some day a million Ford cars would be in the hands of the people has been realized.

It should be stated, however, that this colossal production and sales record is not the result of the activities of the main or parent Ford plant here in Detroit alone. That production record of 1,006,835 cars represents the combined output of the main plant, the twenty-five assembling plants throughout the United States, the Canadian Ford plant and the British or Manchester plant.

Just what the total output of the plant here was in the grand total is not given, but it is safe to assume that 750,000 or more Fords were built in Detroit.

The Canadian Ford plant made and sold 57,352 Ford cars from 1905 to the end of the fiscal year 1915, which was July 30.

The Manchester plant has an annual output capacity for 15,000 cars. It is not known how many have been made there, but it is said that more than 30,000 Ford cars are now in operation in England.

—

Rayfield Motor Co. Petitioned

CHRISMAN, ILL., Oct. 7—A petition for involuntary bankruptcy for the Rayfield Motor Co., Chrisman, which has been engaged in the manufacture of small automobiles of the runabout type, was filed in the United States District Court at Danville this week. A. E. Schuckter, secretary and treasurer, and who claims to be one of the principal creditors, filed the petition. Other creditors are C. R. Livingston and W. M. Newkirk, all of Chrisman. Due to the failure of the Bonner Wrench Co., with which the company had been closely affiliated, it has been in financial trouble for the past year.

—

Disco to Announce New Starter—Increases Capital $40,000

DETROIT, MICH., Oct. 11—The Disco Electric Starter Co., will increase the capital stock from $60,000 to $100,000, the extra $40,000 being subscribed by the present stockholders.

It is said that this is a preliminary for a still larger increase which will become necessary to enable the company to build larger factory accommodation and to install the special machinery necessary for large production.

At the present time the company has contracts which are said to amount to $1,000,000 and is running night and day. Mr. Hackett, general manager, expects to put on the market very shortly a new and improved type of double unit starter and generator. It will be cheap enough to be within the reach of the car manufacturer making a low-priced car and powerful enough for cars of the $5,000 class. The machine was electrically designed by Prof. Benjamin F. Bailey of the University of Michigan, the mechanical features being the work of F. M. Guy.

—

Delco 1915 Output Will Be 125,000 Systems

DAYTON, OHIO, Oct. 12—During the month of September, the Delco factory at Dayton, produced 14,515 complete systems of starting, lighting and ignition equipment, in addition to many separate ignition systems.

This was the largest month's business the company has ever produced, and brings the number since Jan. 1 up to nearly 100,000 systems. The factory is still behind its schedules, and will build upwards of 125,000 systems this year.

In the meantime, the work on the new building is progressing. It is a concrete, brick faced structure and five stories have been poured. The brick facing has already begun to appear, and will be completed within a very few weeks after the concrete part is done.

This new building will more than double the floorspace of the Delco plant. It is an entire block in length, 420 ft. to be exact, and 88 ft. in width.

—

Disco Starter on Denby Truck

DETROIT, MICH., Oct. 11—The Disco Electric Starter Co. has been awarded the contract for electrical equipment for use by the Denby Motor Truck Co.

—

$500 Fines in Crown Co. Case

LOUISVILLE, KY., Oct. 9—In the Federal Court here to-day, technical pleas of guilty to a charge of using the mails to defraud were entered by C. H. Lambert, A. B. Lambert and B. F. Lambert, and fines of $500 each were assessed by Judge Walter Evans. The cases against the Lamberts grew out of transactions in which they, as representatives of the Crown Motor Car Co. of New Albany, Ind., accepted orders for automobiles when they knew, according to the District Attorney, that there were no cars available for sale.

176,428 Cars Registered in Ohio

Nearly 50 Per Cent Increase Over 1914 Total—13,600 Chauffeurs Register

COLUMBUS, OHIO, Oct. 9—Up to Oct. 8 of this year the Ohio Automobile Department registered 176,428 automobiles, which is almost 50 per cent increase over the total registration last year, when 121,400 cars were registered. It is figured that the increase of 50 per cent will be reached before the end of the year as the total registration will probably surpass 181,250, which is the figure to show the 50 per cent increase.

Chauffeurs to the number of 13,600 have been licensed. This is only a small increase over last year, but the constitutionality of the chauffeurs' license law is attacked in a suit now pending in the Franklin County Court of Appeals and the department is not enforcing the law at present. An effort will be made to have the law amended in case the Ohio Legislature is called in special session during the winter.

222,025 Automobile Owners in New York State

ALBANY, N. Y., Oct. 9—Registrations of automobiles in this State up to Oct. 1 this year amounted to 222,025, compared with 164,438 in the same period a year ago. Total registrations for 1914 were but 170,171.

This registration compares with a population in this State, according to the June census, of 9,250,000, an average of an automobile for every forty-four persons in the State.

Receipts of the Automobile Bureau thus far this year have amounted to $1,824,315, all of which will be expended in maintaining and building the roads of the State.

Three-Wheeled Tractor, $945

LOS ANGELES, Oct. 11—The Union Tool Co., Torrance, Cal., is placing on the market a three-wheeled agricultural tractor which is to sell for $945. It is provided with a two-cylinder motor and weighs complete 4000 lb. The overall length is 13 ft. 1 in., the width 6 ft. 7 in., and the height 3 ft. 11 in. This is the first model and is marketed after three years of experiments.

Wisconsin Registrations Gain 25,008

MILWAUKEE, WIS., Oct. 8—Wisconsin's 1915 registration up to Oct. 2 showed a gain of 25,008 over the total registry of 1914, bearing out predictions made early this year that the Badger State would absorb no less than 25,000 new cars from Jan. 1 to Dec. 31, 1915. The total registry on Oct. 4 was 78,169, compared with 53,161 on Dec. 31, 1914. Not only is the prediction of a gain of 25,000 in Wisconsin registrations borne out, but prospects are for a total registration of not less than 80,000 by the end of the year. On Saturday, Oct. 2, for instance, the secretary of state issued 101 new licenses and the daily average is from seventy-five to eighty. The effect of the show given by the Milwaukee Automobile Dealers, Inc., at the annual State fair in Milwaukee, Sept. 13 to 17, seems to be evident in the rush of applications for licenses during the four weeks immediately following the fair, and present indications show no abatement of the demand.

Iowa Cars Average $800 to $900 in Value

DES MOINES, IA., Oct. 9—Figures from the state automobile department of Iowa show that Iowans are not dodging the income tax although the purchase of 50,000 automobiles by Iowans in one year while the income tax returns show more wealthy inhabitants in the District of Columbia than in Iowa leads a Washington, D. C., newspaper to believe otherwise.

The Iowa secretary of state estimates that only 10 or 12 per cent of the 150,000 automobiles in Iowa cost in excess of $2,000 each, that only 20 per cent cost $1,500 or over, that over 50 per cent are cars costing from $400 to $500 and that the average value of all cars in the state is between $800 and $900. This seems to refute the assumption of the Washington paper that the ability to own an automobile is evidence of a $4,000 income. The fact is that most of the car owners in Iowa are farmers and salaried men with incomes ranging from $1,500 to $3,000 a year. A census taken of the automobiles owned by persons connected with a Des Moines newspaper shows that ten out of sixteen cars owned are the property of workers in the mechanical departments—printers, pressmen, stereotypers, etc.—who make on the average about $1,200 a year as governed by the union scale. These facts free Iowans from any suspicion of income tax dodging, for it shows that most of Iowa's automobiles are owned by people of moderate means.

New Danger Signals at Long Island Grade Crossings

NEW YORK CITY, Oct. 11—As a further safeguard against the recklessness of automobile drivers at grade crossings the Long Island Railroad is adopting a new form of watchman's danger signal. It has the word "stop" painted in large white letters on an 18-in. red disk.

Standard Tractor Under $700

To Be One-Man Outfit of Good Size—Some Features of Construction

DETROIT, MICH., Oct. 11—The farm tractor to be made by the Standard-Detroit Tractor Co., is to sell at under $700, and to be a one-man outfit, but not too small in size, the officers of the company believing that economy of labor demands that even on the smallest sized farms a tractor should be used as large as one man can operate satisfactorily.

As reported briefly in last week's issue of THE AUTOMOBILE, prominent men in the automobile industry are connected with the new concern. The stockholders are principally officers of the Federal Motor Truck Co. It is the object of the company to build tractors in every way up to the present truck standard as to materials and workmanship.

G. S. Jacobs is the designer of the tractor. He was formerly connected with the Oakland Motor Car Co. and the Rapid Motor Vehicle Co., Pontiac, Mich., also the Rumeley Co., La Porte, Ind. The first experimental models were brought out in 1914 and tests have been going on with different models ever since in various parts of the country.

Although the final specifications have not all been decided upon, the constructional features of the tractor will be four-cylinder block motor of 30 to 35 hp.; two front wheels with 8 in. steel tires, two rear drive wheels each with 24 in. wide tires, a gearset fully inclosed and running on roller bearings and final drive by chain. The chassis will be of special design, but many standard automobile parts will be used.

The officers of the company are: M. L. Pulcher, president; Charles F. Mellish, vice-president; L. W. Goodenough, treasurer; F. G. Jacobs, secretary. G. S. Jacobs is manager. Edward P. Hammond, president of the Gemmer Mfg. Co.; Thomas E. Reeder, president of the Federal Motor Truck Co. together with the officers, form the board of directors.

In last week's issue of THE AUTOMOBILE it was erroneously stated that Edward P. Gemmer, was one of the incorporators.

2487 Tractors in Kansas

TOPEKA, KAN., Oct. 8—J. C. Mohler, secretary of the State Board of Agriculture, has completed a census showing 2487 tractors in the State on March 1. Barton county, the leading wheat producing county, has the largest number, 123. The larger number of tractors is in the corn belt. Thirty-seven counties in that district have 1209 tractors.

Chevrolet Changes Name

Current Earnings are at Rate of $2,500,000 Per Annum or 12½% on Stock

FLINT, MICH., Oct. 8—The Chevrolet Motor Co. has changed its name to that of Chevrolet Motor Co. of Michigan.

NEW YORK CITY, Oct. 9—The constituent company of the new Chevrolet Motor Co., it is stated, shows earnings in the twelve and one-half months ended Aug. 14 last of $965,000, which is equivalent to 4.8 per cent on the capital stock outstanding. Current earnings are at the rate of $2,500,000 per annum, or 12½ per cent on the capital stock of $20,000,000.

With the introduction of funds raised from the sale of capital stock the company's balance sheet, as of Aug. 14, 1915, will show as follows:

ASSETS	
Cash in banks and on hand	$5,346,111
Accounts and notes receivable less reserves	359,992
Inventories of finished cars, merchandise on hand and in transit, and work in process	1,475,394
Investments	748,500
Charges deferred to future operations and suspense items	69,438
Invested—real estate, buildings, fixtures, equipment, tools, patent rights, developments, good will, etc.	13,237,242
Total	$21,236,677
LIABILITIES	
Accounts payable and accrued liabilities	$1,141,677
Mortgage on Beekman Avenue plant at Tarrytown, N. Y.	95,000
Capital stock	20,000,000
	$21,236,679

New Company to Continue Making Randall-Faichney Products

BOSTON, MASS., Oct. 9—The property of the Randall-Faichney Co., has been disposed of at auction, the sale taking place at the property, 76 Atherton Street, Jamaica Plain. The entire property was bought by the creditors' committee for $150,000. Under the plan of reorganization which will now be carried out a new company to be called the Randall-Faichney Co., Inc., with new cash capital and a conservative board of directors will at once be formed and take over the property.

The property consists of a building and 33,609 ft. of land.

Rubber Shortage in Berlin

LONDON, ENG., Oct. 9—According to a report received in this city from a person who recently left Berlin, there is a great shortage of raw materials. Rubber has been smuggled in in the form of sausages. The scarcity is so great that no private individual in Berlin is allowed to use his automobile, except the doctors. Rubber floors have been taken up and every scrap in any shape or form has been used.

Austria Confiscates All Tires

ZURICH, Oct. 9 (via London)—The Austrian Ministry of War is reported to have confiscated the entire supply of pneumatic and other rubber tires in Austria, including those of private ownership, new or old. The owners of the tires are required to deliver them up within twenty-four hours under penalty of a year's imprisonment.

Three Market Changes

NEW YORK CITY, Oct. 12—Markets this week made but two gains and one loss. The trading was normal, but the buying was dull. The steel markets ranged very low with but a few sales taking place. The copper markets opened the week firm on a good inquiry from war material manufacturers, but a steady recession in standard copper at London caused prospective buyers to withdraw from that market. There are many stocks of copper afloat from all over the country. The total supplies on Sept. 30 were 23,628 tons against 29,519 tons in the same period last year, with total deliveries 28,759 tons, against 30,518 tons. Antimony is receiving fair support. Aluminum was very active during the week, with several increases in prices recorded. The demand continues in excess of the supplies and holders at the close asked 50 and 55 cents per pound in carload lots. There was not much new business in the local rubber market last week and buyers were inclned to allow matters to shape their course a little more definitely for a few days. Up-River fine quoted at 57½ cents. The oil and lubricant markets were a bit unsteady during the middle of the week but returned to normal. Pennsylvania crude oil advanced 5 cents in the middle of the week, but the following day closed at its normal price. There was also an advance in gasoline of 1 cent. It is expected that within a month the price will have advanced to 25 cents to consumers.

Porto Rico Increases American Car Purchases

SAN JUAN, PORTO RICO, Sept. 23—The past year has shown a large increase in the number of automobiles purchased in the island, 548 cars having been imported during the twelve months ending with June 30, 1915. No foreign cars have been sold here in recent years. There are approximately 2000 cars in the island, most of them in constant use.

There is no demand here for high-priced cars. Automobile tires showed a falling off during the past year as compared with the previous fiscal year. Tire imports for 1915 were $251,426; for 1914, $296,201, and for 1913, $241,714.

The automobile here is used as the chief means of passenger transportation, both private and public, about the island. There are regular motor lines running from this city to all sections of the island. Mail to about half of the towns is delivered by automobile, and most of the established motor lines operate an express and parcel-delivery service.

Recently the jitney has made its appearance here in competition with an interurban railroad running 5 miles between the towns of Catano and Bayamon. The railroad has carried 500,000 passengers a year and the fare has been 10 cents until the arrival of the jitney. Then the railroad cut the fare to 5 cents, but the jitney continues to get many passengers at the old fare of 10 cents.

Indiana Mutual Insurance Co. Formed

SOUTH BEND, IND., Oct. 9—The Indiana Mutual Automobile Insurance Co., with home offices in Laporte, Ind., has been organized. Articles of incorporation have been filed with the secretary of state and have been approved by the auditor of state. The company has been organized for the purpose of insuring against fire, but the policy will also provide an amount of $50 to be paid in case

of theft. The officers of the corporation are: Frank J. Cook, LaCrosse, president; Dr. F. H. Henderson, vice-president; Fred C. Brewer, treasurer; Clay M. Donner, secretary. The last three named reside at El Paso, Ill.

—

Insurance Assn. in South Dakota

PIERRE, S. D., Oct. 9—For the first time since the law was passed March 10 advantage has been taken of the possibility of forming an automobile insurance company. F. H. Johnson, F. H. Reed, G. C. Cottan, L. C. Nichols and A. B. Fairbank have incorporated the American Auto Indemnity Assn. of Sioux Falls.

—

Bosch Magneto Wins Contracts

NEW YORK CITY, Oct. 8—The Bosch Magneto Co. has signed contracts as follows: Chandler Motor Car Co., Brewster & Co., Stewart Motor Corp., R. M. Owen & Co., W. Irving Twombly, Atterbury Motor Car Co., Blair Motor Truck Co. and Brockway Motor Truck Co.

—

Berger New York Lozier Manager

DETROIT, MICH., Oct. 9—L. B. Berger, who was sales manager of the Lozier Motor Co., has been appointed manager of the New York branch.

—

Stutz Has Running Board

NEW YORK CITY, Oct. 13—Owing to an engraver's mistake the advertisement of the Stutz Motor Car Co., which appeared in THE AUTOMOBILE for Sept. 30, included a photograph of the Stutz Bulldog Special which showed no running board. This was removed accidentally when trimming the cut.

Securities Markets Dull

—

Sharp Declines in Many Issues—Losses Small—Trading Normal

NEW YORK CITY, Oct. 11—The securities markets remained dull throughout the whole of last week. There were very few changes. A few small losses occurred. Trading conditions were at a standstill and there were but a few bidders in sight. There were a few exceptional good closing prices. Firestone closed at 575, or 15 points higher than last week. This tire issue was the only one to make a high gain, the rest making either minor gains or losses. The specialties markets were a bit firmer, making many good gains and but few losses. The he viest gain took place on Saturday when at the closing Packard was quoted at 139, a gain of 13 points. Then followed closely to that Chalmers, with a gain of 11 points. General Motors also made a few points gain, when it closed at 341. The rest of the issues remained dull.

Detroit Quotations Active

The Detroit issues were a bit more active last week, there being no decline made during the whole week. Continental Motor featured the market there when on Saturday it closed at the high mark of 325, a total gain of 30 points. Chalmers closed at 157½, or 18 points gain. Packard's closing bid was 137, making the gain 11 points. These were the main gains, the rest of the issues in the active stocks closing a little above the average mark of last week's rating. The inactive stocks made no changes. The trading conditions in Detroit were very firm and many shares changed hands.

—

To List Chalmers Common Stock on New York Curb

NEW YORK CITY, Oct. 9—The Chalmers Motor Co., Detroit, has applied to list 50,000 shares of common stock of par value $100 on the New York curb. Action will be taken at once to list it on the Philadelphia Stock Exchange.

The Chalmers company has outstanding $5,000,000 common stock, paying 10 per cent dividends, and $1,185,500 7 per cent cumulative preferred. The original issue of preferred was $1,500,000, and $313,500 has been retired.

The company is free of bonded debt. Its balance sheet shows that cash on hand alone considerably exceeds the company's current liabilities. It is stated that after making allowances for paying off all liabilities and the preferred stock at par, the assets, without taking into any consideration the item of good will, would equal over $120 per share on the $5,000,000 common stock.

—

R-C-H Creditors Receive Dividend

DETROIT, MICH., Oct. 9—A fourth dividend of 10 per cent, representing about $34,000, is being mailed by the Security Trust Co., trustee, to the creditors of the old R-C-H Corp. This brings the total paid in dividends to about $312,500, and it is possible that a further dividend payment will be forthcoming later.

11,000 Maxwell Cars in 2 Months

August and Sept. Earnings Estimated at 15% on Common Stock

DETROIT, MICH, Oct. 9—August and September earnings of the Maxwell Motor Co. are understood to have been better than 15 per cent on its $12,778,000 common stock, compared with 6½ per cent the previous year. The company for August and September delivered nearly 11,000 cars, or at the rate of better than 65,000 cars a year, which is substantially 100 per cent in excess of the production for the fiscal year to July 31.

Newcastle Plant a Unit

INDIANAPOLIS, IND., Oct. 8—After a little more than two years' operation as an independent enterprise, the Newcastle, Ind., plant of the Maxwell Motor Co., Detroit, Mich., again reverts to the parent company and will be operated as one of the units of the company itself. As is well known, the Newcastle plant has been largely devoted to the production of parts for Maxwell cars and replacements for products of several older companies that were merged in the Maxwell organization several years ago. For this purpose the Maxwell-Newcastle Manufacturing Co. was organized, which took over the plant under lease. The larger and growing demands of Maxwell car production at the present time, however, have necessitated a rearrangement in which is involved resumption of responsibility for the plant.

Ford Tractor Building to Be Enlarged

DETROIT, MICH., Oct. 11—The building upon the property of Henry Ford in Dearborn, near here, where the first Ford tractors were built, is to be greatly enlarged so that the building of experimental tractors on a large scale may be started. It is said that many changes will be made in the new demonstrators and that a long time will probably elapse before the final model for actual marketing purposes will be selected. It is also stated that the domonstrations given by the tractors at the recent Michigan State Fair led to many suggestions for their improvement.

Ford Buys More Indianapolis Land

INDIANAPOLIS, IND., Oct. 8—To increase its real estate holdings in Indianapolis for what is thought to be further development, the Ford Motor Co. has announced the purchase of ground immediately west of its plant on Southeastern Avenue.

The ground has 161 ft. frontage on Southeastern Avenue, is 270 ft. deep on the east side and 239 ft. on the west. The ground was purchased at different times from several different owners.

Attaches of the Ford branch are refusing to say at this time, what the ground is to be used for, except a general statement that it will be added to the Ford business. The present Ford building is unable to answer the demands of local business, although there is a square frontage of more than 200,000 sq. ft.

The Ford production for 1916 in the local branch will be more than 19,000 cars, and this will tax to the extreme the production facilities. However, it is safe to assume that this ground was acquired for building purposes and that a large addition is soon to be built to the Ford plant.

The idea of the Ford tractor is now obtaining shape, and the Ford agents are asking when this tractor will be available for selling. A. H. Smith, manager of the local Ford branch, refuses to say anything very definite as to when the Ford tractor will be announced. However, it is understood that these Ford tractors will be assembled in Indianapolis.

Norma Bearings Now Made in America

NEW YORK CITY, Oct. 9—The Norma Co. of America has started active manufacture of its ball bearings in this country. As early as 1912, the Norma company had anticipated the necessity for making its bearings in this country and a small shop was established for preliminary and experimental work. The results of these experiments were so successful that the shop activities of the company were gradually extended and the facilities enlarged, primarily with a view to meeting emergency demands where the imported bearings were not immediately available.

The outbreak of the war and the subsequent inability to obtain its goods from the plant at Cannstatt, Germany, promised to seriously affect the business of the company. Fortunately, however, the company was well stocked, which sufficed to tide over the situation until the American factory could be enlarged sufficiently to meet the demand. The company now has a completely equipped plant being steadily enlarged and increased in capacity.

S. A. Machine Co. Formed

DETROIT, MICH., Oct. 9—The S. A. Machine Co. has been formed by A. W. Sorensen, formerly president and general manager of the Trio Mfg. Co. and J. B. Allen, formerly of the Olds Motor Works, to make automobile parts and specialties. The plant is located at 518 E. Woodbridge Street.

New Overland Office Building

Will Be Seven Stories, 373 by 63 Ft.—Dodge Office Building Completed

TOLEDO, OHIO, Oct. 8—The old Overland administration building, formerly the Pope plant, is to be torn down to make room for a new factory structure. This latest addition to the production end of the business will compel the Willys-Overland Co., to vacate its present quarters and the entire office staff will be moved into a larger building as soon as it is completed.

The new office quarters will be located on Willys Park Boulevard. The building will be seven-stories high, 373 ft. long and 63 ft. wide. It will contain 165,000 sq. ft. of floorspace and will be made fireproof throughout.

McGraw Rubber to Open Factory Branches on Coast

EAST PALESTINE, OHIO, Oct. 11—The McGraw Tire & Rubber Co. will open direct factory branches on the Pacific Coast in San Francisco, Los Angeles and Portland, these to be under the district management of S. L. Warner, formerly superintendent of branches; C. K. Whittaker, formerly Kansas City manager, will be sales manager. C. H. Connelly, formerly Buffalo manager, will be in charge of the Kansas City branch; G. J. Marshall, formerly assistant branch manager in Buffalo, will take charge of the Kansas City branch; R. G. Nelson has been made superintendent of branches. At the annual meeting of the stockholders the officers and directors were re-elected.

To Build Cars in Pittsburgh

PITTSBURGH, PA., Oct. 9—A company formed by prominent local men and headed by E. E. Gregg, will build popular priced touring cars and roadsters in this city. Options have been secured on two plants said to have a yearly capacity of 10,000 cars. Production is scheduled to begin Jan. 1.

Dodge Administration Bldg. Completed

DETROIT, MICH., Oct. 7—The enlarged and rearranged administration building of Dodge Bros. was completed a few days ago. It is now one of the largest in the city, being a four-story structure, 80 by 400 ft. The first three floors are practically entirely taken up by offices, either for executives or for departments, such as the sales and advertising departments, which occupy most of the main floor. The fourth floor has the various dining rooms and rest and lounging rooms, there being one private din-

ing room for the Dodge brothers, a cafe for the executives and heads of departments, a cafeteria with room for 500 for the office employees, a smoking room and a large rest room for women.

—

Detroit Commercial Car Co. in Pontiac Chassis Plant

PONTIAC, MICH., Oct. 7—The Detroit Commercial Car Co., which was recently organized in Detroit, to make the Detroit package delivery wagon, which is selling at $690 and $745, according to the style of body, will occupy part of the factory building of the Pontiac Chassis Co., which concern is making the chassis for the truck company.

According to President W. D. Paine, of the latter company, schedules have been laid out for an output of 5000 trucks the first year.

—

Bowser Suit Against Wayne Oil Tank Withdrawn

FORT WAYNE, IND., Oct. 11—S. F. Bowser & Co., this city, has withdrawn its suit in the U. S. district court of Chicago, brought against the Wayne Oil Tank & Pump Co., also of this city, for alleged infringement on two patents on fill pipe caps. Both companies are manufacturers of gasoline and oil storage systems and fuel and oil dispensers. One patent in question involved the Red Sentry outfit, a sidewalk type of fuel dispenser. The other patent covered important features in wheeled pumps for serving gasoline to automobilists and for handling other volatile oils.

Judge Carpenter gave the Bowser company the option of answering some thirty interrogatories propounded by the defendant or withdrawing its suit.

—

Wells Adds New Products

FOND DU LAC, Wis., Oct. 8—The R. C. Wells Mfg. Co., Fond du Lac, Wis., manufacturing the Wells starter-generator and other electrical devices for the motor car industry, is ready to market numerous new inventions, including a three-step dimmer switch which will be made in large quantities. The company also has contracts for 15,000 to 20,000 automatic fuel economizers to be delivered each month for the next six months. R. H. Mansfield, for many years with Cutler-Hammer Mfg. Co., Milwaukee, recently purchased the Wells company.

—

Eight-Hour Day for Stewart-Warner

CHICAGO, ILL., Oct. 11—All the plants of the Stewart-Warner Speedometer Corp. were placed upon an 8-hr. basis, beginning last week, and rates were increased so that the men receive the same per day that they received under the previous 54-hr. schedule.

Carriage Factories May Build Cars

—

$2,000,000 Canadian Co. May Enter Moderate-Priced Car Field in Spring

MONTREAL, QUE., Oct. 8—Carriage Factories may enter the automobile field. It is understood that very shortly Brockville will be selected for the manufacture of a light, moderate priced car, which will be ready for the trade next spring. The concern which is entirely a Canadian one, represents a consolidation of the principal Canadian companies manufacturing carriages and sleighs, including the Canadian Carriage Co., Brockville; Munroe & McIntosh of Alexandra; Tudhope Carriage Co. of Orillia and the Heney Carriage and Harness Co. of Montreal. These four companies are understood to produce about 75 per cent of the carriages, sleighs and light vehicles used in the Dominion of Canada. The company has an authorized capital of $2,000,000 common stock; $2,000,000, 7 per cent accumulative preferred stock and $1,000,000 first mortgage 6 per cent bonds. There is now outstanding $1,200,000 of preferred, $1,200,000 of the common, and $500,000 of the bonds. Directors of the company include, J. P. Tudhope, W. F. Brock, of the Royal Bank of Canada; W. F. Heney, W. J. Sheppard, director of the Royal Bank of Canada; J. A. MacKay, Hugo Munroe and T. J. Storey, president of the Atlas Motor Co., Brockville, Ont.

Blowout at 86 M.P.H. Kills Tester on Indianapolis Speedway

INDIANAPOLIS, IND., Oct. 8—Albert Johnson, twenty-five, of Detroit, Mich., driver of a Packard test car, was fatally injured and his mechanician, Ross Robinson, twenty, was seriously hurt when the car traveling 86 m.p.h. turned turtle on the Indianapolis Motor Speedway, Monday afternoon, Oct. 4. Johnson died on the operating table at the Methodist Hospital Monday evening. Robinson may recover.

The accident occurred when the car blew a tire on the south turn into the back stretch of the track.

Robinson, Johnson and two other Packard experts have been at the speedway two weeks testing the Packard Twin Six which developed a high speed and they were making the last lap of a twenty-five mile spin when the car overturned. Coroner Poole investigated the accident and found Johnson's death was caused by shock following the accident.

The Packard experts had driven the car thousands of miles at the speedway and it was the object to give the car as much testing in a few weeks as an owner would give it in several years. Special attention had been given to the tires and the drivers were instructed to change tires whenever one showed any signs of wear. The tire that blew was on the right front wheel, the car turning over several times.

—

Farmers See Cars at Western Washington Fair

PUYALLUP, WASH., Oct. 6—The Western Washington Fair held this year Sept. 28 to Oct 3 proved an excellent advertising medium for the Tacoma and Seattle automobile dealers, who occupied upward of twenty booths in the new automobile building on the grounds. While but few actual sales were made during the exhibition, considerable interest was manifested in the new models and the dealers were placed in touch with many of the small truck farmers, who will purchase cars this year in greater numbers than ever before.

—

Two Killed in Columbus Race

COLUMBUS, OHIO, Oct. 11—Two fatal accidents occurred at the Columbus Driving Park, Oct. 10, when a 100-mile automobile race was run with a good field of cars entered. The accidents did not occur in the race but were the result of trial heats made to test a Stutz racing car. The car had been acting badly and driver Douglas Gray, 23, of Lima, and his mechanician, Clarence Robinson, colored, of Columbus, were both almost instantly killed when a tire blew on the front wheel and the car was overturned. The car was making about 50 m.p.h. when the tire burst and it was turned over twice.

Dr. Harry E. McCord, a practicing physician of Cincinnati, driving a Cino was declared a winner in 1 hr. 42 min. and 12 sec., but this was protested by Harry McNay, also in a Cino, who was said to have finished 9 sec. later. McNay protested that a mistake had been made in the signal system and that he was the winner. Until the dispute is settled the $1,000 prize money is withheld from any of the drivers.

In third place was Charles Mowery, of Loudenville in a Stutz, and fourth place went to W. G. Lake, of Mt. Vernon, in an Everitt.

—

Marshall with Remington Arms

NEW YORK CITY, Oct. 13—W. C. Marshall, treasurer of the Metropolitan Section of the Society of Automobile Engineers, has taken a position in the production department of the Remington Arms Co., Bridgeport, Conn., and will resign from the governing committee of the section.

Service Assn. Scope Broadened

Indiana Managers to Include Repair and Distributing Heads—Plan National

INDIANAPOLIS, IND., Oct. 10—Members of the Indiana Automobile Service Managers' Assn. at their regular meeting at the Hotel Severin, Saturday afternoon, voted to include in the organization the service managers of repair and distributing agencies in addition to those of manufacturers and accessory houses. They heard a series of addresses on the purposes of the organization and discussed the probability of an early national organization into which the sectional agencies similar to Indiana organization will be incorporated.

To Meet Regularly

The Indiana organization will meet regularly on the second Saturday of October, January and April of each year, and each summer will have an outing. H. W. Drew of the Nordyke & Marmon Co., president of the Service Managers' Assn., in his opening address outlined the purpose of the organization.

A well-adjusted system of co-operation among all service agencies must be obtained, and in the furtherance of this the Indiana organization expects to do pioneer work, he said.

Four other papers were read, each of which was a report on some phase of the National Automobile Chamber of Commerce Service Managers' Convention in Detroit, Mich., last June. The papers were presented by O. W. Williams of the Inter-States Motor Co., Muncie, Ind., G. E. Drawe of the Pathfinder Motor Car Manufacturing Co., Indianapolis, J. O. Myers of the National Motor Vehicle Co., and E. W. Cotton of the McFarlan Motor Car Co., Connersville, Ind. Among the members from outside of Indianapolis who attended were: E. W. Cotton of the McFarlan Motor Car Co., and F. R. Leeds of the Lexington Howard Co., Connersville, G. B. Braithwaite of the Apperson Automobile Co., and H. R. Perry of the Haynes Automobile Co., Kokomo, R. J. Ellston of the Westcott Co., Richmond and J. H. Hopper of the Remy Electric Co., Anderson.

All local factories were represented at the meeting. The association will assist in a movement to standardize service policies.

—

Safety Men Meet in Detroit

DETROIT, MICH., Oct. 12—The Safety First Federation of America will meet here in convention Oct. 19 and 20. More than 100 delegates from many states are expected, and many matters of direct interest to the automobilist will be considered. Among the men who are to address the convention are Henry B. Joy, president of the Packard Motor Car Co.; William McAdoo, chief magistrate of New York City; Job H. Lippincott, former commissioner of motor vehicles of New Jersey; Charles M. Talbot, director of streets, St. Louis; Harry P. Coffin, chairman of Public Safety Commission of Portland, Ore.; Alonzo P. Erwing, president of the Greater Detroit Safety First Organization; Ralph Folks, public welfare commissioner, New York; Charles C. Healy, superintendent of police, Chicago; John Gillespie, police commissioner, Detroit.

—

Los Angeles Garagemen Busy Making Cars Into Speedsters

LOS ANGELES, CAL., Oct. 7—A new field has been opened up to the garagemen of Los Angeles by the craze for rebuilt cars which has taken southern California. The Ward Motor Car Co., which has opened a large garage at 1788-98 West Washington Street, is making a specialty of rebuilding. Used cars are cut down and transformed into speedster types. This garage handles a stock of accessories and supplies and does some general repairing, but the rebuilding is the main work of the corps of mechanics.

—

U. S. L. Convention Oct. 12-15

NIAGARA FALLS, N. Y., Oct. 11—The annual convention of the United States Light and Heat Corp., this city, will fall on Oct. 12 to 15. The branch managers and salesmen from all sections of the country will be in attendance. Business sessions will be held and daily addresses by President J. Allen Smith, vice-president and general manager Harry Ackerman and sales manager, C. C. Bradford will be made. New sales and advertising policies will be explained to the visiting salesmen.

—

Must Prove Chauffeur Negligent

LANSING, MICH., Oct. 9—The Supreme Court of Michigan has ruled that in cases of accidents to children, which occur on the streets, it must be plainly shown or proven that the chauffeur or automobile driver is negligent, before damages can be allowed the injured.

In the opinion written by Judge Steere, the latter says: "Drivers upon highways are not held as insurers against accidents arising from negligence of children or their parents, and though in law such negligence in a particular case may not be a defense as contributory negligence, for a driver also guilty of negligence, the fact of an accident does not establish liability or raise a presumption that the driver is negligent."

The ruling was made in the case of six-year old Orilla Barger, Detroit. She was struck by an automobile owned by Edward R. Russell on Gratiot Avenue, in 1911. In the Wayne County Court, a jury allowed the child, through her mother, $975 damages. An appeal was taken to the Supreme Court which now has sent the case back for a new trial, with the above mentioned ruling.

—

National Safety Council to Meet in Philadelphia

PHILADELPHIA, PA., Oct. 13—The fourth annual safety congress of the National Safety Council will be held at the Bellevue-Stratford Hotel in this city on Oct. 19, 20 and 21. There is to be an elaborate exhibition of safety devices of all sorts, and special lectures will be delivered on the use of safety appliances in the various industries.

—

Good Market for Light Cars in India

NEW YORK CITY, Oct. 9—There is a good market for light cars in India, according to a report given out by a local man. A reply, given him by a friend in India who had been asked for information in regard to the sale of automobiles in that country, stated that there are already many light cars in that country and that it is probable that a good market could be made there for the right car at the right place. It would be used daily for journeys between the bungalow, club and office.

—

20,555 Cars in Virginia

RICHMOND, VA., Oct. 9—From 4020 automobile licenses issued by the Secretary of the Commonwealth for the year 1911, netting a revenue of $40,000, the number of license taxes sold has increased to 20,555 for the nine months of 1915, with a revenue of $170,000, all of which goes to the State Highway Commission for road improvement. Including the revenue from 1911 to date the State has received more than $479,000 from the sale of license tags to automobiles.

—

Wisconsin Association Improves Laws

MILWAUKEE, WIS., Oct. 9—The Wisconsin State Automobile Association spent $465 at the 1915 session of the Wisconsin Legislature. The association succeeded in retaining the former excellent automobile code on the statute books, besides adding several amendments to increase the safety of motoring.

—

Highway Engineering in U. of M.

ANN ARBOR, MICH., Oct. 9—A graduate fellowship to be known as the R. D. Chapin Fellowship in Highway Engineering has been given to the University of Michigan by Roy D. Chapin, president of the Hudson Motor Car Co. The fund donated provides an annual payment of $500.

Tulsa Co. to Make Oils—Cosden & Co., Tulsa, Okla., J. S. Cosden, president, will build a plant costing $200,000 for manufacturing wax, automobile oils and cylinder oils.

Miles Co. Making Trailers—The Miles Mfg. Co., 306 East Franklin Street, Jackson, Mich., which has been making concrete machinery is now also making the Miles automobile trailer.

Beardsley's New Plant—The Beardsley Electric Co. will build a plant at Culver City, Cal., near Los Angeles, to make electric passenger cars.

Motor Specialties Adds—A new boiler room, 50 by 60 ft., and a machine shop are being erected for the Motor Specialties Co., Muskegon, Mich., the expenditure on the buildings being estimated at $10,000.

Sterling Truck to Aid—The Sterling Motor Truck Co. Forty-sixth Avenue and Rogers Street, West Allis, Milwaukee, has awarded contracts for a factory addition which will practically double its capacity.

Carriage Co. to Make Automobiles—The Cortland Cart & Carriage Co., Sidney, N. Y., increased its capitalization from $75,000 to $225,000 to take up the manufacture of automobiles. It expects to continue its carriage business as usual.

To Make Sight Feed Oilers—Harvey Strong and L. C. Perkins of the Des Moines Fuel & Lime Co., has organized the Perkins Mfg. Co., for the manufacture of a sight feed oiler for Ford cars. They have established a plant at 51 Mulberry Street, Des Moines. The initial order is for 50,000 oilers to Zinke & Co., Chicago, Ill.

Detroit Welding Opens New Shop—The Detroit Welding Co., which started in business eighteen months ago at Leib and Larned Streets, Detroit, Mich., has opened a new shop at 814 West Jefferson Avenue. The shop is fitted out to take care of welding of cast iron, aluminum steel, brass, brake rods, steel tanks, and do general welding work.

Allen Dedicates New Plant—The new plant of the Allen Motor Co., Fostoria, Ohio, has been completed. The new structure, composed of concrete and steel, covers a floorspace of 150 by 100 ft. It will be used for the testing of Allen-Sommer motors. With the completion of this plant the annual output of motors is expected to be tripled.

Aluminum Castings New Building—The new machine shop of the Aluminum Castings Co., Detroit, Mich., is now complete and in use. It is 176 by 105 ft. The company is now making a specialty of the machining of bronze bushings from any one of its forty to fifty Lynux alloys, and also to handle a large quantity of bronze back babbitt lined bearing work.

Hancock Co. Rushed—The Hancock Mfg. Co., which makes parts and now has 130 men on its payroll, is working nights three days a week till 9 o'clock, being unable to turn out orders on schedule by working by day only. Orders on the books now will keep the plant busy all winter. Although a large addition was put up this summer a further extension may be necessary.

To Make Tires in San Jose—A tire plant employing 800 to 1000 men will be established in San Jose, Cal., by the Aero-Cushion Tire Co. The plant will be established on a site near the corner of First and Maple Streets. It is expected that the company will be turning out tires within ninety days. The tire itself is made up of 65 per cent porous rubber, 30 per cent air and 5 per cent of chemicals. It is placed inside the casings, and, it is claimed, practically indestructible.

Auto Wheel Triples Production—Since last April the Auto Wheel Co., Lansing, Mich., has almost tripled its production capacity through the erection of an addition, 60 by 180 ft., partly two stories high, a new boiler room, ten new dry kilns, a large hydraulic hub press, new boilers and other additions. At that time about fifty men were employed, while now more than 150 are on the pay roll. The daily output is now forty sets of truck wheels and 225 sets of other automobile wheels. Orders on hand are said to enable the company to keep the plant busy for the next twelve months.

The Week in the Industry

Langworthy Resigns—M. B. Langworthy has resigned as president of the King Motor Sales Co. of New York, Buffalo, N. Y.

Grady Succeeds Bush—J. E. Grady has succeeded W. T. Bush as general sales manager of the Studebaker Corp. of Canada. He will devote all his time to the retail trade.

McKenny Resigns—J. A. McKenny has resigned his position with the Dayton Buick Co., Dayton, Ohio, to become sales manager of the Standard Motor Car Co., Dayton, agent for the Chalmers.

Swinehart Tire Moves—The Swinehart Tire & Rubber Co. branch at Boston, Mass., has moved into its new quarters at 62 Brookline Avenue.

Robinson Makes Change—Percy Robinson, formerly manager of the Moline Knight branch in Boston, Mass., has resigned to join the sales force of the Premier and Westcott cars in that city.

Sowers Reno Mgr.—Cuyler Lee, distributer of the Maxwell and Packard lines in California, has opened a branch establishment in Reno, Nev., and has appointed George Sowers as manager.

Royce Louisville Tire Mgr.—The American Tire Co., distributor for the American tire, has opened a salesroom at 525 South Third Street, Louisville, Ky. J. W. Royce is manager of the concern.

Promotion for Flinn—C. W. Flinn, for the past year identified with the Chevrolet Motor Co. of New England at the Boston, Mass., branch, has been promoted to be manager of the company's branch at Stamford, Conn.

White Joins Curtiss—H. C. White has accepted a position with the Curtiss Aeroplane Co. as production engineer. He was formerly connected with the Pierce-Arrow Motor Car Co. as superintendent of the assembling departments.

Dealer

New Baltimore Tire Co.—The Gilson Sales Co., 213-215 Guilford Avenue, Baltimore, has become the Maryland distributor for the tires of the Canvas Tread Tire Co., Utica, N. Y.

Free Tire Service in Dayton—The Free Tire Service Co. is the name of a new concern, opened at 208 West Third Street, Dayton, Ohio. C. R. Connor, formerly of Huntington, W. Va., and O. R. Rowe compose the firm. Free tire service will be given to owners within a radius of 5 miles from Dayton.

Motor Men in New Roles

Mathews Mohawk Tire Sales Mgr.—C. C. Mathews, formerly with the United States Tire Co., has taken on the representation of the Mohawk tire, and will handle the sales in the southern part of Indiana, with headquarters at Evansville.

Boland Is Expanding—H. M. Boland, Worcester, Mass., agent for the Hupmobile and proprietor of the Kelly-Springfield Tire Co., has bought out also the Forer & Danziger Co., that had the Johns-Manville service station at 703 Main Street.

Herron Joins Springfield Body—Murray Herron has joined the Springfield Metal Body Co., Springfield, Mass., in the capacity of comptroller. He was formerly a branch and service manager in Detroit for the Stewart-Warner Speedometer Corp.

Allan Burd District Branch Mgr.—Robert Allan has been appointed district branch manager for northern California by the Burd High Compression Ring Co., Rockford, Ill. His headquarters will be at San Francisco, at 847 Phelan Building.

Avery Packard Service Head—L. C. Avery has been appointed technical manager of the Packard-Cleveland Motor Co., Cleveland, Ohio, succeeding A. P. Welburn, who has returned to Boston. J. J. McCauley, former assistant to Mr. Welburn, has been promoted to the Packard truck sales department.

Schaefer with Goodyear—W. H. Schaefer, who was a member of the truck specification department of the Packard Motor Car Co. for the past three years, is now with the sales department of the Goodyear Tire & Rubber Co., Akron, Ohio, where he will give special attention to the foreign business of that concern.

Andress Heads Cleveland Truck Agency—H. D. Andress, formerly division sales manager of the Chase Motor Truck Co., Syracuse, N. Y., has been appointed general manager of the Safe Motor Sales Co., 6504-06 Euclid Avenue, Cleveland. This company handles the Vim light delivery car, the Chase truck and the Simplex trailer.

Bolland Made Pres.—J. B. Bolland of St. Louis has been made president and general manager of the Bittel-Leftwich Service Co., Springfield, Ill. He succeeds A. Turner, who has been transferred to St. Louis to take up a new berth with the same firm in that city. The company will handle automobile supplies and accessories of all kinds.

Boston Dodge Enlarges Organization—The Henshaw Motor Co., Boston Dodge distributor, has materially enlarged its organization. The additions include W. L. Shepard, formerly treasurer Shepard Mfg. Co., Melrose; W. A. Maynard, formerly Chalmers dealer in New Haven, Conn.; T. A. Guild, I. W. Sibley, F. W. Bailey, F. H. Lewis and E. A. Walker.

Duffy Heads N. Y. Standard—S. G. Duffy is president and L. J. Goldman vice-president of the Duffy Motors Corp., 1895 Broadway, New York City, to handle the Standard Eight in that city.

Schiller on Pacific Coast—J. P. Schiller, Jr., has been sent to the Pacific Northwest as special service representative of the Willard Storage Battery Co., Cleveland, Ohio. He will make his headquarters in Seattle.

Wicks Heads Milwaukee Westinghouse—The Westinghouse Lamp Co., New York, on Oct. 15 started operation in its new Western lamp works at Milwaukee, where a maximum output of 500,000 globes per month is ultimately planned. The company has previously operated large works at Bloomfield, N. J., and New York City, but has long felt the need of a large plant in the Middle West. Accordingly, the company purchased the former Milwaukee plant of the Kissel Motor Car Co., Hartford, Wis., at Thirty-first and Center Streets, and since then has been equipping it for the production of lamps of all voltages and sizes. Five hundred girls are employed at Milwaukee. F. W. Wicks, formerly of the New York plant, is general manager at Milwaukee.

Dealer

Holtzer-Cabot Offices Moved—The executive offices and factory of the Holtzer-Cabot Electric Co., Boston, formerly located in Brookline, together with the Boston factories of the company, have just been removed into the company's new plant in Roxbury, Mass.

Cleveland Overland Leases—The Overland-Cleveland Co., 6604 Euclid Avenue, Cleveland, Ohio, branch distributor for the Overland company, has purchased the 99-year lease on an extensive piece of land in the immediate rear of the sales and service station. The property has 95 ft. frontage on Carnegie Avenue, extending 584 ft. deep.

VOL. XXXIII. NEW YORK—THURSDAY, OCTOBER 21, 1915—CHICAGO No. 17

THE AUTOMOBILE

French Plants Make V Motors

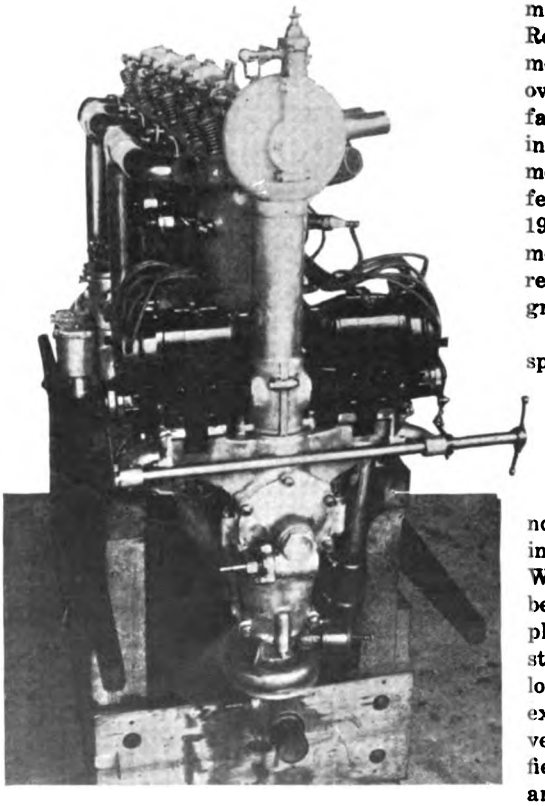
War Proves Star Type Aero Engines Useless—Eights and Twelves of Automobile Design Replace Freaks—May Affect European Car Practice

By W. F. Bradley
Special Representative of THE AUTOMOBILE *with the Allied Armies in France*

ONE of the many unexpected results of the war has been that automobile manufacturers have become aeroplane engine makers. One of the after-results will be the greater development of the six-, eight- and twelve-cylinder automobile. This is explained by the fact that all the new motors for aeroplanes are of the fixed cylinder, water-cooled type, and although specially made for service in the air, are of the same general design as the motors used in a car. The end of the war will see the French manufacturers with much of experience on multi-cylinder engines directly applicable to their car work.

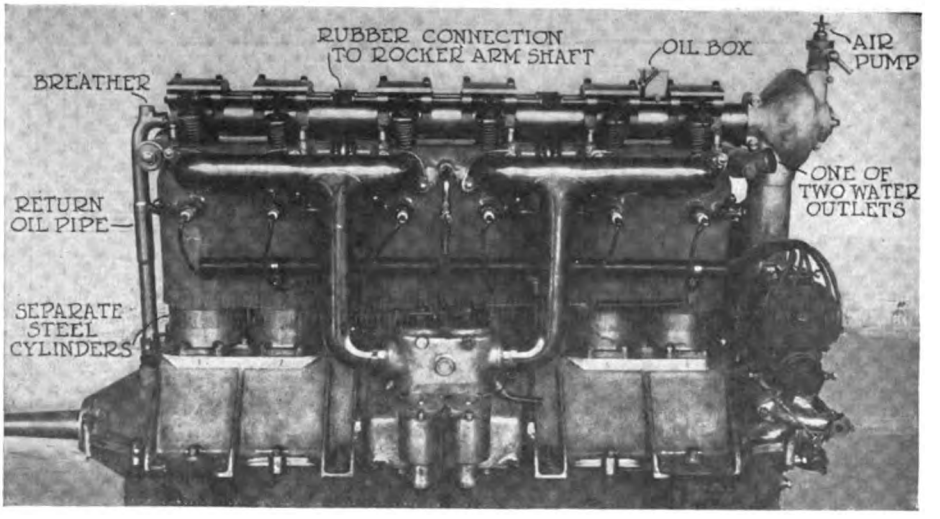
Renault is building sixes, eights and twelves; Lorraine-Dietrich is producing sixes and twelves; Hispano-Suiza has an all-aluminum eight-cylinder motor; Darracq is supplying a successful piston valve six, and an overhead-valve six; Peugeot is interested in an overhead-valve eight; Engineer Henry, late of Peugeot racing department, is supplying the army with a twin four of the same general design as his famous racing motors; Panhard is interested in sixes and eights; De Dion Bouton specializes in eights; Sunbeam is delivering twelves to both the British and the French armies.

There has been a revolution in the French aeroplane motor world since August, 1914. When the armies went forth to war, France had staked her reputation on rotary, air-cooled motors, or motors of the star type, most of them air-cooled. The only largely used motor which at all approximated the automobile type was the Renault eight-cylinder air-cooled model. When France was delirious over flying every automobile manufacturer in the Republic set his drawing office staff to work on aeroplane motors, and every factory produced a few engines for air service. But in 1909 the Gnome rotary air-cooled motor came into the field, and by reason of its low weight, secured a great advantage over all rivals.



End view Mercedes aviation motor, showing vertical shaft operating water pump, revolution counter, two magnetos, camshaft and gasoline pressure pump located on top of housing

At that time flying was merely a sporting proposition, and flights were of comparatively short duration. Under these conditions the Gnome, despite its inherent defects, gave better results than any fixed cylinder water-cooled motor, and was not long in obtaining a predominating position in the aeronautical world. When interest in the sport of flying began to wane, and when the aeroplane became a purely military instrument, the French manufacturers lost interest in their aeroplane motor experiments, and individual inventors turned their energies to other fields. In France alone between 100 and 150 different makes of aeroplane motors were designed and built between 1908 and 1912. It would be quicker to give the names of the fac-



Carbureter side Mercedes six-cylinder aviation motor, showing features of design

tories which have not dabbled in aviation than to quote those having produced and abandoned a special aero engine.

For several years aeroplane and automobile engine development has been on entirely different lines. The men who built for the air took no interest in engines for the road; and, with the single exception of Renault, no automobile manufacturer had any interest in the aerial business. In consequence, the automobile high-efficiency development of the last four years has had no counterpart in the aerial field.

Testing Aero Types

This was evident to close observers before the war, and has been made apparent to the entire world since the outbreak of hostilities. In 1913 the Automobile Club of France decided on an aeroplane motor competition, the essential condition of which was that the motors should run for 100 hr.—twelve days of 8 hr. each, and one day of 4 hr.—half an hour being allowed each day for starting and minor adjustments, consumption above a certain maximum being penalized by a reduction of the theoretical number of hours run, and consumption below that maximum being compensated by an increase in the calculated hours of operation. Thus of two motors having operated 100 hr., one might have its time increased by reason of gasoline economy, and a second might have its time decreased because of excessive consumption.

No automobile manufacturer entered this competition. The interested parties were aeroplane motor specialists. The eight motors entered comprised Gnome types, fixed cylinder air-cooled, star type motors, and one nine-cylinder water-cooled engine of the star type. Not a single engine actually ran 100 hr. without mechanical trouble. The best was the water-cooled engine, which was in operation for 98 hr., 58 min., 30 sec., the balance of time being lost in changing a magneto distributer. This motor was the only one consuming less than the official allowance of 350 grams gasoline and oil per horsepower-hour, and in consequence was credited with 123 hr. running. No. 1 Gnome type had six stops for mechanical failures, during which pistons, balance weights, and valves were changed and the motor entirely overhauled. It ran 98 hr., but as its fuel consumption was 494 grams per horsepower-hour, its theoretical running time was reduced to a little less than 56 hr. Two other motors from this factory had to be withdrawn owing to mechanical defects. A similar rotary type had five stops on the first day and went out with a cracked cylinder. A second and similar motor averaged four stops for each of the four days it was running.

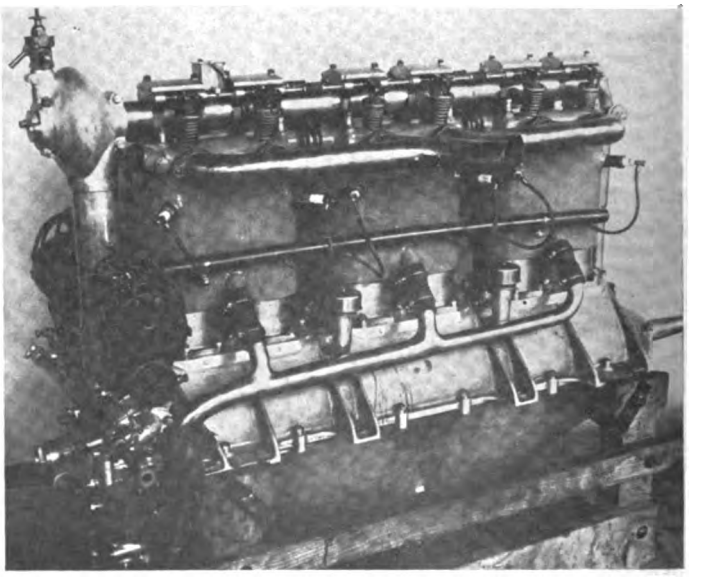
The excessive gasoline and oil consumption of the air-cooled rotaries was really alarming. The Gnome which ran for 98 hr. had an oil consumption practically 30 per cent of its gasoline consumption, while some of the more recent automobile type aviation engines have an oil consumption only 0.057 of the gasoline supply. Ignoring fuel, the Gnome type is undoubtedly the lightest motor in existence. Also on a basis of 5 hr. operation, and with units up to 100 hp. this motor is lighter than any other type. But for higher powers, and for longer non-stop runs the fixed cylinder automobile type is superior.

Considering the Gnome and the nine-cylinder water-cooled motor taking part in this competition, estimating on 60 hp. for one hour, the weight of the Gnome is 249 lb., and of the water-cooled engine 480 lb. With fuel and supplies for 10 hr. running the Gnome weighed 807 lb. and the water-cooled engine 777 lbs. For 100 hr. operation the weights are 6387 for the Gnome and 3747 lb. for the water-cooled rival.

Another comparison, in which the Gnome, the nine-cylinder water-cooled motor and one of the latest eight-cylinder water-cooled engines are compared on the basis of 100 hr. running and the same horsepower developed, works out as follows:

Motor	Lb.
Gnome type	2,841
Nine-cylinder water-cooled aviation motor	2,203
Eight-cylinder water-cooled automobile type	1,366

Up to 100 hp., and for flights not exceeding 4 hr., the Gnome type motor is equal to any other, when considered on a weight basis. Thus it is satisfactory for single-seaters used for observing the effects of artillery fire. The development of long range heavily armored aeroplanes has called for motors of 150 to 250 hp. For this class of aeroplane the rotary is useless. Its high gasoline and particularly its high oil consumption make it one of the heaviest motors in existence. It fails also on the score of reliability, for military statistics, prepared during the first year of war, show that one make of rotary motor averaged 4 hr. useful flying and another 12 hr. effective service, before going to the scrap heap. Inaccessibility is another defect of the rotary, and is largely responsible for the short average life. Under peace conditions skilled mechanics were always in attendance. On war service unskilled hands have to be trusted with these very delicate pieces of mechanism, and succeed in considerably shortening their lives. It is difficult to silence the rotary air-cooled motor, while the fixed-cylinder water-cooled motor

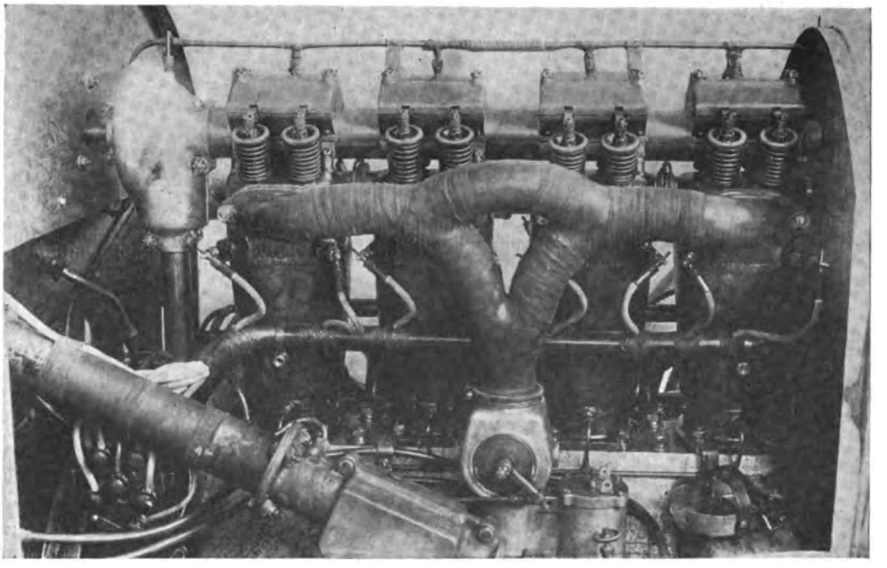


Exhaust side Mercedes aviation six which uses separate steel cylinders but a common waterjacket for each pair

can be silenced as effectively as the engine between the frame members of a car. Now that aeroplanes are built with engines totalling from 500 to 1000 hp., silence is an important feature.

Car Makers Take Responsibility

Very early in the war it was recognized that the rotary type in which France had specialized was not the best kind of engine for active service conditions. Gradually the contracts for this type of engine were reduced until they are now approaching the vanishing point, and at the same time automobile manufacturers were encouraged to build for aviation purposes. At the present time all the automobile factories are busy and the aero-motor specialists are transferring their attention to fixed cylinder types. The elimination of the nine-cylinder water-cooled star-type motor, which was mentioned in connection with the automobile club competition, has been due to the tendency to catch fire in the air. This is a defect almost inherent to this class of design, and is not found in the automobile-type engine. When seven machines were burned in seven days owing to this motor defect, the manufacturer found himself cut off the army lists.



Mercedes racing motor. Compare this with aviation type on opposite page

Effect on Automobile Uncertain

It is not safe to predict a wholesale reversal to sixes, eights and twelves for car purposes, as the result of the experience French automobile manufacturers have acquired in the aviation field. When, after examining his twelve-cylinder water-cooled aviation motor, the remark was made to Louis Renault: "I suppose you will use this type of motor in your cars." Renault replied, "It would be anti-commercial." Despite this reply, there is reason to believe that after the war many of the high-grade cars built in France, and also some in England, will have eight and twelve-cylinders.

Germany's aeroplane motor experience is in striking contrast to that of France. It was not until 1911 or 1912 that Germany began to doubt the efficiency of her Zeppelins and to turn her attention to the creation of an aeroplane fleet. At that time she was dependent on France for her aeroplane motors, and the rotary-type Gnome figured largely in German sporting events. The change was rapid. Under military direction the automobile factories of Germany devoted themselves to the task of producing a strong, reliable, water-cooled fixed-cylinder motor of the automobile type. The government regulations put out of consideration anything in the nature of a copy of the French Gnome, and the automobile factories left to their own resources naturally adapted their automobile experience to aviation work and built engines which had much in common with their standard, or racing design.

The past year has shown that the German military authorities were more far-seeing than those of France, for they adopted a type of motor which has proved satisfactory under war conditions, while, since the war began, France has made a transformation which would have been considered miraculous under ordinary conditions. The war has also shown the thoroughness with which Germany has tackled the aviation motor problem. Benz and Mercedes were the two most interested German factories. Benz produced six-cylinder overhead valve motors, with push rods and rockers, and Mercedes developed a six-cylinder type with overhead valves and overhead camshaft.

Germany Showed Most Forethought

It is now evident that Mercedes' sudden interest in French automobile racing was due to her anxiety to perfect the aviation type of motor the German army wanted in big quantities. After winning the Grand Prix race in 1908, Mercedes took no interest in French automobile races for a period of five years. In 1913 she refused to be drawn into the French Grand Prix run under limited fuel rules. But in the autumn of that year she suddenly appeared at an open race at Le Mans with a fleet of five cars the existence of which nobody had suspected. The cars arrived late on the course and they went back to Germany the morning after the race. But for the driver of one of the cars shedding his hood while traveling at speed, no foreigner would have obtained a glimpse of the power plants of these cars. It was difficult to find a reason for Mercedes suddenly deciding to participate in a secondary French road race, the winning of which could not have brought much credit, and which was certainly costly. It was finally concluded that the Belgian agent, Pilette was instrumental in getting the cars together, and the matter was forgotten.

It is now clear that the factory itself was decidedly interested in those cars, for they carried the new Mercedes aviation motor, and the race was taken advantage of to subject them to a more searching test than it was possible to give them in the air. Only one of these cars was allowed to leave the German factory. It was purchased by E. C. Patterson of Chicago, and was driven in the 1914 elimination

trials at Indianapolis by Ralph De Palma. The car did not start in the race. This motor had been designed for a maximum of 1400 r.p.m. in the air, and when made to approach 2000 on the track periodic vibration developed. This was known to the Mercedes factory before the French race was run, and the necessity of studying balance at high engine speeds was the important lesson learned by the Mercedes engineers.

Last Grand Prix Was Final Test

At the last French Grand Prix at Lyons, run a couple of weeks before the declaration of war, Mercedes again put in a full team of cars. Complete mystery surrounded the motors of these cars. The Mercedes engineers and officials allowed members of the technical press to walk around, crawl under, or crawl over their racing cars, but they allowed nobody to peep under the hood. Precautions against peeping Toms comprised a 10-ft. wall, a watch dog and a night and day watchman, an oak door to the garage, a couple of mechanics sleeping by the side of the cars, and a chain and padlock around each bonnet. Persuasion and cajolery were alike powerless to extract information regarding the motors, and the meager facts finally obtained were mainly secured by strategy. French offers to buy these cars were refused. Only one machine was sold, this being the car with which Ralph De Palma won the Indianapolis race this year.

While these Mercedes motors were specially built for the French Grand Prix, their design was that of the Mercedes aviation engine. It is rather a bitter reflection for the French that only a few days before war was declared, a German firm was making use of French road races to test and perfect military aeroplane motors. It was declared at the time of the race that the German Emperor sent a personal telegram of congratulations to the Mercedes team at Lyons. This is not surprising, now that it is realized the winning of the race was a matter of military importance.

Mercedes motors, which are found on about 80 per cent of German aeroplanes, are considered the best from across the Rhine. Other makes, even when captured in good condition, are not used on French machines. At the suggestion of the French military authorities the Renault and Lorraine-Dietrich factories now build duplicates of the German Mercedes motor and fit them to their own biplanes. Parts built in these French factories are interchangeable with the German motors, so that every machine captured in a reasonably good condition means not only a loss to the enemy, but a gain to the Allies.

Details of Mercedes Motor

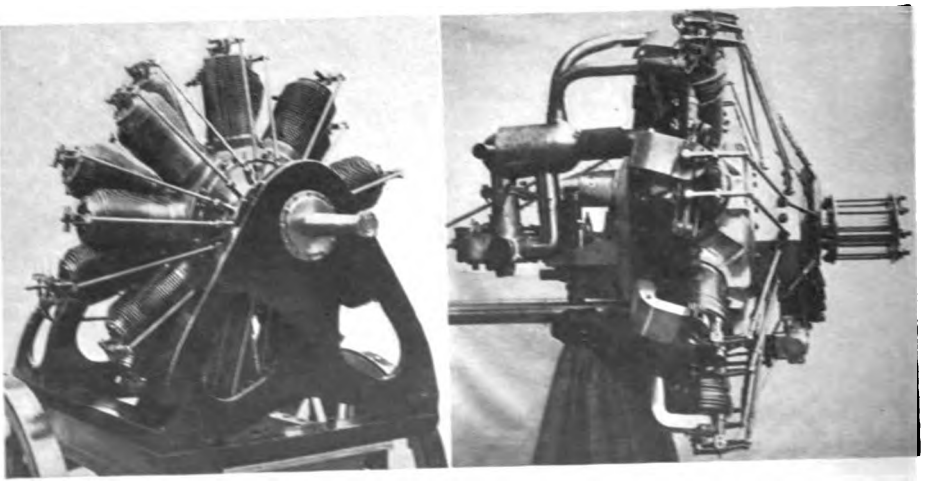
Germany's leading aviation motor is a six-cylinder Mercedes measuring 4.7 by 5.5-in. bore and stroke. As is fairly well known, the cylinders are separate and machined from steel forgings, with inclined valves mounted in the head. The same general design is found throughout the aerial engines and those used for speed work on the road and track. The illustrations of the aeroplane motor give the impression of cylinders cast in pairs. This, however, is not so, the cylinders being separate, as in the case of the four-cylinder racing model, but with a common waterjacket for each pair on the six.

In the last French Grand Prix race at Lyons, Mercedes was alone in the use of separate steel cylinders, every other competitor—French, English, Italian and Swiss—seeking rigidity by means of a compact block casting. The radical difference between the two types of motors led to some discussion at the time as to which school held the balance of advantages; the German partisans maintained that the more careful machining, both inside and out, rendered possible with separate steel cylinders, outweighed whatever rigidity advantages there might be with a block casting as developed by the French and Italian schools.

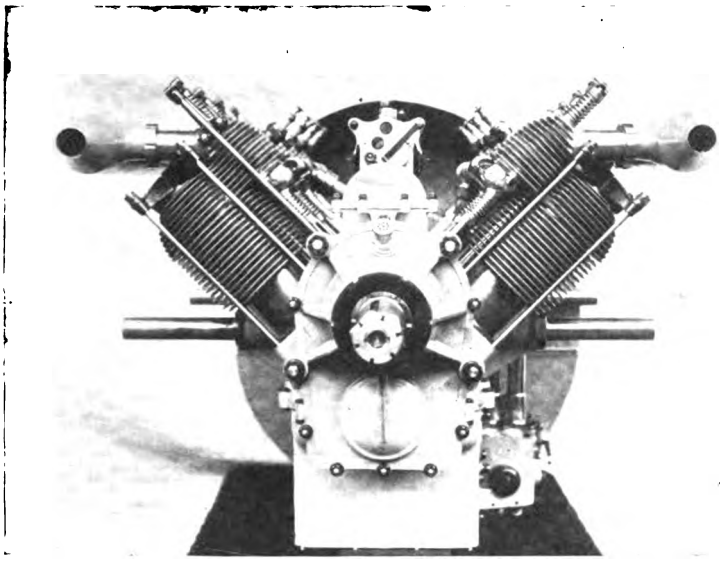
It is now seen that Mercedes had another reason for adopting separate steel cylinders. Her motor had primarily been designed for aeroplane work, in which weight was an important consideration, and road racing was only indulged in to test the design and construction of the aeroplane engine. Her engineers were thus bound to the use of separate steel cylinders.

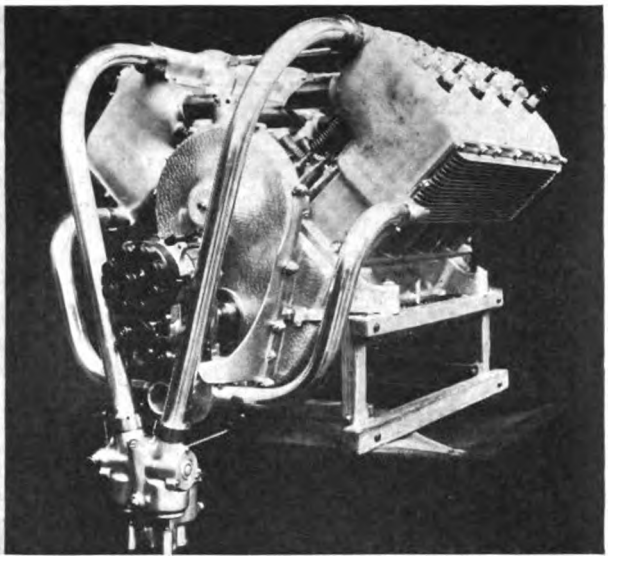
Cylinders Are Complicated

With a view to weight reduction, cylinder walls are made as thin as possible, but the necessary rigidity is obtained by a series of four circular ribs around the barrel of each cylinder. Valve seats and guides are screwed into the head of the cylinder and then acetylene welded in position. A steel waterjacket is welded to the cylinder or cylinders, there



Left—Eighteen cylinder rotary, Gnome type motor. The war has proved the death knell of this design. Right—Nine-cylinder water-cooled Salmson motor which has a tendency to catch fire





Left—Renault eight-cylinder air-cooled aviation motor with housing removed. Note propeller is mounted on end of camshaft. This is the only successful air-cooled motor in France. Right—Panhard eight-cylinder water-cooled type

being a jacket per cylinder in the racing type and a jacket for two adjacent cylinders in the aeroplane engine. Each cylinder is held to the aluminum crankcase by eight bolts. Despite the apparent external dissimilarity, the cylinder design and construction is identical in the two types of motors.

The aeroplane motor has but two valves per cylinder, whereas on the racing four pair intakes and exhaust are employed. Valve diameter on the six is 2⅛ in., with a valve lift of 5/16 in. It will be observed that the valve area is small compared with the area on this and other makes of racing motors, but it is not desirable that the number of revolutions in the air should exceed 1400.

The crankshaft is a very fine piece of work, entirely hollow, and not merely bored for oil leads, attached to the upper half of the crankcase in four white metal bearings. The diameter of the shaft is 2⅛ in. and the four bearings have a uniform length of 2¾ in. I-section connecting-rods, machined all over and drilled in the webs were used on the original Mercedes motors, but it has been possible to save weight without any loss of strength by the use of hollow circular section connecting-rods. Four bolts are used for each connecting-rod end. Wristpins are hollow, with a diameter of 1 5/16 in. The upper end of the rod carries a cast-iron bushing drilled with a large number of lubrication holes of about 3/16 in. diameter.

At one end of the crankshaft is a bevel pinion driving an inclosed vertical shaft by means of which power is transmitted to all the accessory organs. At the upper end of the shaft a bevel pinion engages with a gear on the end of the overhead camshaft; at the extreme lower end is the water pump; the revolution counter is mounted just below the crankshaft. Just above the crankshaft, and to left and right of the vertical housing, two Bosch high-tension magnetos are mounted and driven by bevel gearing. The current is led to two plugs in each cylinder, mounted horizontally just below the valves. The magnetos are synchronized, the advance and retard mechanism being common to the two units. Mounted on the top of the vertical housing containing the camshaft drive pinion is a gasoline air pump driven by eccentric off the end of the camshaft.

Overhead Camshaft Very Light

The overhead valve mechanism is a very fine example of careful designing and skilled construction. A light steel housing attached to the cylinder heads by means of twelve vertical studs, carries the hollow camshaft, the rocker arms, and their hollow shafts. It has not been possible to get the exact weight, but judging by the feel the entire structure cannot weigh more than 4 or 5 lb. Detailed structure can easily be gathered from the illustrations.

It will be seen that the inner end of each rocker is forked and receives a roller in contact with the face of the cam. The outer end is split and also threaded to receive a stud, the hardened end of which is in contact with the extremity of the valve stem. The stud allows of tappet adjustment and can be locked in its correct position by tightening up the bolt going through the two split ends of the rocker. Very elaborate oiling arrangements are provided. Lubricant is carried up the vertical shaft housing, through the hollow camshaft to the main camshaft bearings and also through the hollow rocker arm shafts to the rocker arm bearings. At the end of the camshaft housing opposite the drive, there is a steel return oil pipe leading into the base chamber, and a breather is mounted on the top of this pipe.

Provision for Splash

Although the rockers are lubricated internally, provision is also made for a supply by splash. On the inner face of the cast aluminum cover mounted on the top of each pair of rockers are two thin aluminum splash guards which cause the oil splashed up by the cams to be thrown into an oil duct in the body of each rocker and from here it flows to the bearings. The rocker arm shafts are common to two rockers, but are joined up by means of oil-resisting rubber connections. This gives two continuous hollow shafts fed with oil flowing by gravity from an oil box on the top of the housing. On the racing model the rocker arm shafts are not hollow, the delivery being entirely by splash, with level maintained by means of hand pump and overhead pipe.

The supply of oil is contained in the base chamber, which has its greatest depth in the center. There are aluminum baffle plates placed horizontally at both front and rear end of the crank chamber to prevent the tilting of the engine in either direction throwing the oil into the end cylinders. The oil pump is in the bottom of the central well and can be withdrawn independently of the crank chamber. Power is transmitted to the oil pump off the vertical shaft by means of a horizontal shaft in the base chamber, and worm gearing.

A duplex Mercedes carbureter is fitted, supplying respectively the three forward and the three rear cylinders. Although the pair are cast together, each carbureter has its own float chamber and its own main and pilot jets; the two throttles are connected and operated together. The carbureter, which is of cast aluminum, is bolted close up to the base chamber and obtains a jacket of water from the central pair of cylinders.

British Duty Threatens French Exports

$11,000,000 Trade with England Before War May Be Rendered Impossible After Peace Is Declared by 33⅓ Per Cent Tariff

PARIS, Sept. 24—When Chancellor of the Exchequer McKenna announced a British import duty of 33 1/3 per cent on all foreign automobiles, the first instinct of the French manufacturer was to utter a cry of despair. In the last year for which complete figures are available, France exported automobiles to the value of $43,500,000; of this amount $11,000,000 represented trade with England. A 33 1/3 per cent duty is prohibitive. There is not a French manufacturer who could stand up under it. The best equipped firms would seek to minimize the duty by shipping bare chassis without tires, wheels, magnetos, carbureters, etc., finishing the machines in England, and would make arrangements for the establishment of erecting and body shops. For the bulk of the French trade the British market would be completely closed. There are at least fifteen factories in France sending from 40 to 65 per cent of their output into England. For these the conditions looked hopeless.

Since the announcement the situation has been examined more calmly, and the dominant feeling is that the tariff is a war measure to be repealed as soon as peace has been declared. It ought to be explained that it is more a hope than a belief that England will abolish the tax after the war. No official announcement has been made by the English authorities, and until the newspaper publication of the budget proposals the leaders of the French automobile industry had no idea of a British tax on foreign cars.

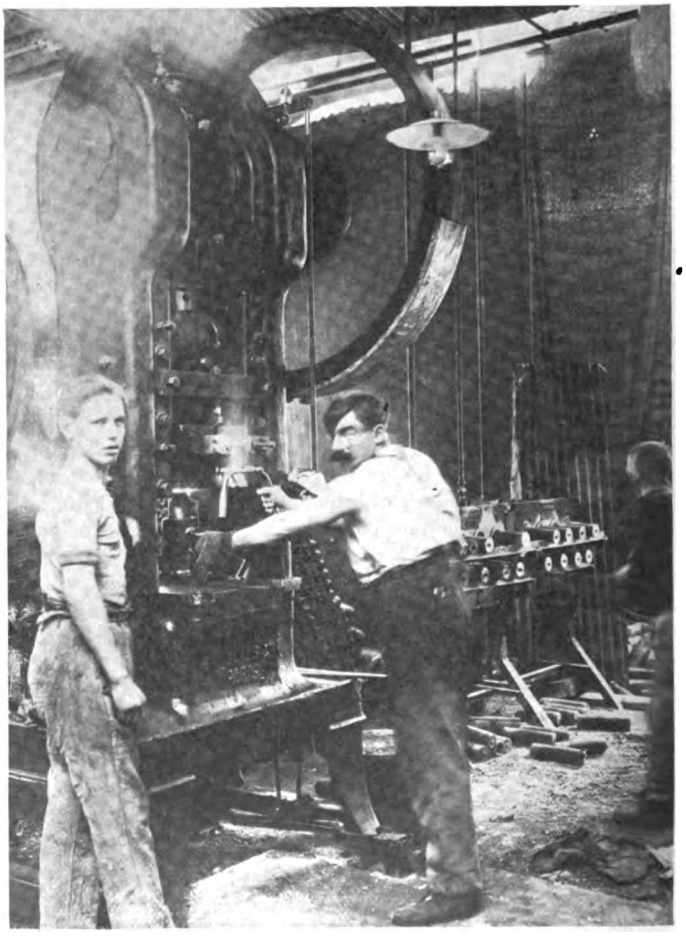
The belief is expressed that the import duties have been adopted as a protection against America, and that later preferential treatment will be given to France and her Allies. As the French automobile factories are able to export but a minute number of cars, the tax does not at present seriously touch this country. With wonderful unanimity the French manufacturers declare that it is inconceivable for England to maintain a tariff barrier against French goods, and particularly against such an important industry as the automobile. Nevertheless, those firms having important interests in England, and particularly those French factories registered under the English limited liability law, will continue to feel very nervous until they have obtained definite assurance that England's action is directed against neutral countries and not against the Allied nations. When ideas have taken concrete form, it is more than likely there will be an understanding between France and England on the matter of tariffs, and that joint action will be taken to prevent America getting hold of the European automobile market in the interval immediately after the war.

Factories Deal Direct

Up to the present France has been apparently indifferent to the danger of American competition, for it is practically impossible to sell any automobiles in that country except to the government. This business, too, must be done direct. The most skilled and persistent intermediaries have been forced out, and all business is now being done direct between the French Government and the American factories, or between the factories and the official banking representatives of the French State. A few enterprising dealers have made arrangements to put American cars on the French market as soon as ever there was a possibility of selling, which means as soon as ever the war was over, but they have not imported or sold any cars up to the present. Among the American firms having entered into arrangements with French dealers are Buick, Overland, Studebaker, Chalmers and Saxon. These dealers recognize that when the war comes to a close it will be impossible to find a new French automobile anywhere in the country, and that no factory will be in a position to produce in any quantities in less than six months. Thus, the man who can deliver at once will certain do business. As the end of the war is not immediately in view, it was not surprising that public attention was not drawn to these preparations for capturing a slice of the French trade. Nevertheless, the authorities have kept a close watch on the situation, and there is every reason to believe that they are prepared to take drastic measures to protect their industry against invasion from any source immediately following the war.

Conditions Different in England

In England conditions are different, for during practically the whole fourteen months of the war there has been a certain private market for foreign cars. It is no exaggeration to say that the British manufacturers are enraged at the possibility of their market being seized by an outsider while they are busy working for the army. Certain manufacturers have led a serious campaign against foreign cars, although the word foreign might best be translated by "American,"



How the French automobile factories are occupied in making war munitions. Stamping a 75-mm. shell. Note the gas furnace heating sixteen shells at the right of the illustration and also pile behind the machine

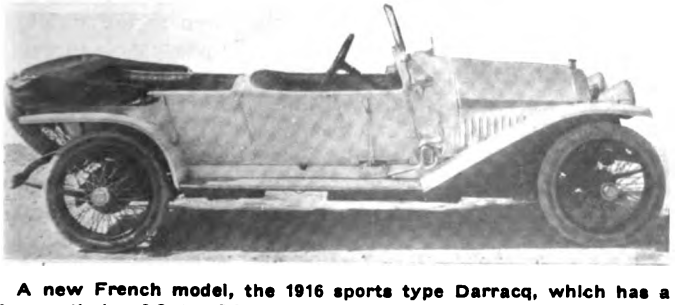
for the only automobiles entering England are those from across the Atlantic. Until only a few days ago, the great majority of the British automobile factories had been requisitioned as a whole by the government and were not in a position to furnish a cent's worth of goods to the private client. Quite recently there has been a slight relaxation and a small portion of the output can go to approved private firms having government contracts and needing automobiles. This applies particularly to trucks. The complaint is not that the factories are losing money, for they are all making as much, if not more than in the most prosperous peace times, but that when the war finished they would find their own market in the hands of the American.

Resentment Against French Factories

The realization that their position was as bad as it possibly could be, tended to raise a little resentment against the French factories, which have never been absolutely forbidden to supply private orders. Dealing with this point, the English manager of a French company declared it was the fault of the Englishmen themselves if their whole business organizations had been seized by the army. "When the threatened march on Paris was averted last September, the entire automobile industry of France was called to a joint meeting with the military authorities. When we were asked if we could make shells, we decided to place the whole of the automobile factories of France at the disposal of the war department. At that time not a single factory was running; most of us did not possess more than 2 per cent of our staffs. Some of our men had already been killed or made prisoners. Nevertheless, within fifteen days we were producing shells. Within a month most of us had as big a payroll as before the war, and since then there has been a steadily progressing output. Where it was possible to do so without interfering with army contracts, we were allowed to fulfill private orders. As we all had a few men not under military obligations, and we all had some raw material in stock, it has been possible throughout the war to produce a small number of private cars. The output is really insignificant compared with peace times, but our initial action saved us from being taken over lock, stock and barrel by the military authorities.

"England unfortunately made the mistake of supposing that the war would be over in six months, or a year at the most, and that the best policy was to 'carry on as usual,' so as to be ready to take advantage of the after-the-war boom. Many British manufacturers declined to accept army contracts, or accepted contracts of an insignificant nature not likely to interfere with their general organization. In consequence there was serious delay in getting the British factories to work on the production of munitions. In several cases it was necessary for the authorities to interfere, militarizing the entire factory, and refusing to allow any private work to be done. The trade realized its mistake at a rather late hour, and is now completely and efficiently organized for helping on the war."

French army automobile drivers carrying out a wayside repair on car damaged by the enemy's guns



A new French model, the 1916 sports type Darracq, which has a four-cylinder 3.3 by 5.5 motor, giving 50 hp. and capable of 65 m.p.h. with four passengers and full equipment

Duty Useless as Protection for British Automobile Manufacturer

LONDON, ENGLAND, Oct. 3—The import duty on American cars has caused no little upheaval in the trade and no doubt will take some little time before it gets back into its normal condition. It is not expected to have a very severe effect on the sale of American cars; the Cadillac being likely to feel it most of all. The Overland people have advanced their price by $250, the Oakland four, $350, the small Oakland six, $225, the Oldsmobile four, $350. I expect the Studebaker four will go up about $325 and the Studebaker six $400.

The American trade have had a large number of meetings and a deputation has waited upon the Chancellor of the Exchequer just to prove to him how ruinous such a tax would be upon the dealers dotted all over the country. There is a distinct feeling that the tax will never be made law, as the amount of money to be collected from it, and also the amount of money that it would prevent going out of the country, is not worth much attention by the government. As a tax to assist British manufacturers, of course it is useless; to do any good it wants to be something like 100 per cent. Probably it will hit the American tire manufacturers very much more than the car people.

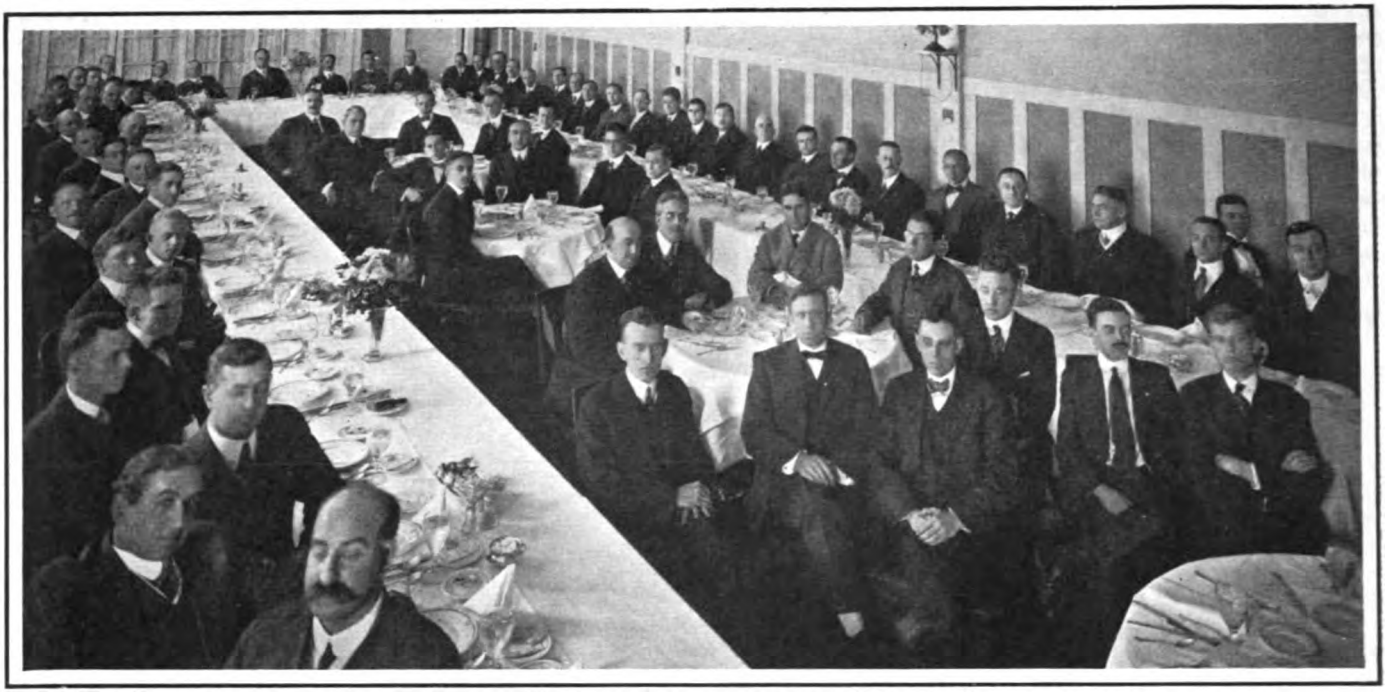
From current advertisements appearing in the English journals it is seen that the government has given some of the commercial vehicle manufacturers a limited release which will enable them to supply vehicles to firms employed upon government work, and it is likely that it will assist the car manufacturers in a similar way.

May Reduce Our Trade with England One-Third

DETROIT, MICH., Oct. 13—George Hutton, representative for Dodge Bros. at Dublin, Ireland, who is at the Dodge plant, in commenting on the new automobile import tax of 33 1/3 per cent just decided upon by Great Britain, said that it will probably cause a reduction of one-third in the importation of American cars, and possibly a greater percentage.

"The new import tax has stirred up a great deal of discussion in England and Ireland and there has been some feeling that it has been directed against the United States. My opinion is that the real purpose was to keep as much money as possible in England. The people generally are living more economically.

"If there was any real passenger car buying in Great Britain now, the reduction in sales would be still greater, but for the past six months we have been selling practically no cars for pleasure only. The people still buying cars are doctors, salesmen, farmers and similar persons.



Banquet of the S. A. E. Standards Committee and Mid-West section held at the Chicago Automobile Club, Thursday evening, Oct. 14

Mid-West S. A. E. Section in Chicago

Many Members from Wisconsin and Indiana—License Brackets and Pump Bases Among a Number of New Standards Ready for Approval of Society—Committee Reports

CHICAGO, ILL., Oct. 15—A Chicago section was added to the family of the Society of Automobile Engineers at the time of the quarterly meeting of the standards committee held here yesterday. In fact, the formation of this section was one of the reasons that the committee held its meeting at Chicago rather than at its Detroit headquarters. The temporary organization took place at a dinner held at the Chicago Automobile Club following the business session of the committee.

For some time, it has been felt that the engineers on the west side of Lake Michigan should get together more often, and a Chicago section has been talked of for more than a year. The name Mid-Western section was adopted, however, as it fits the territory better, than would the name of the city, for it developed at the dinner that the section could draw upon over fifty S. A. E. members in Milwaukee alone to say nothing of those in the other adjacent Wisconsin and Indiana automobile cities.

The work of the temporary organization will be carried through by William H. VanDervoort, president of the S. A. E., as chairman; Mark A. Smith, Standard Oil Co., vice-chairman; Daniel Roesch, Armour Institute, treasurer, and Darwin S. Hatch, *Motor Age*, secretary. As soon as a charter has been granted by the council, the Mid-West section will complete its permanent organization. Indicating the decided interest which is being manifested in the new body was the attendance of seventy-five members at the organization dinner.

Among those who spoke in favor of the Mid-Western section and who gave valuable suggestions to this newest member of the S. A. E. family were David Beecroft of THE AUTOMOBILE, K. W. Zimmerschied, General Motors Co., Herbert L. Connell, Milwaukee Central Continuation School, George W. Dunham and G. H. Conant, chairman and secretary respectively of the Detroit Section S. A. E., W. P. Kennedy, New York City, Prof. P. B. Woodworth, Stevens Institute and Russell Huff.

Iron and Steel Division Reports

On the preceding day several of the divisions of the standards committee held meetings which resulted in reports presented to the committee as a whole yesterday. The first report at the morning session was given by Mr. Zimmerschied and dealt with the work of the iron and steel division. This division has been one of the mainstays of the standards committee and, in the past year, has been engaged in reconciling its early recommendations with the changes which have come about in the industry. At last summer's meeting an extremely complete and comprehensive report was given to the society, and the work now in hand is a still further ironing out of the specifications and recommendations already enforced.

Among the suggestions which will be given to the society next winter is the raising of the limits for phosphor and sulphur content of steel to 0.045 and 0.054 respectively, in order to meet present commercial conditions in the steel industry. Mr. Zimmerschied pointed out that the S. A. E. specifications now cover steels for practically all parts of the car except the very special cases such as ball-race material, etc.

The data relative to test pieces also are being refined and sheets will be issued in the near future covering a modified 2-in. test piece, the flat strip and gray iron test pieces which have been adopted by the American Society for the Testing of Materials and also a standard method of conducting the hardness test. The division also is working to adapt all the

test specifications of the S. A. T. M. to the needs of the automobile industry. The recommendations in these various matters will be ready for presentation to the society in June. There was no discussion.

Among the points of greatest general interest that were made at the meeting of the standards committee was the statement that a properly-designed license plate with figures 3 in. high could be read as distinctly at the usual legal distance as the one with figures 6 in. high. Another was the recommendation by the same division that tail lights be placed centrally over the rear license number.

No Dimmers Recommended

A startling announcement was that by the electrical equipment division that there were no dimming devices on the market that could be recommended by the S. A. E. The committee adopted a uniform location and size for distinguishing marks on the chassis of motors which will be a benefit in the prevention and apprehension of theft of cars. As to the strictly technical work effected by the committee meeting there was a great deal of value in it to the engineers of motor car plants and part makers which also is indirectly valuable to owners as well, such as the standardization of wire sizes, tire pump basis, clutch housings and other features of design which make for uniformity and accessibility of the product.

A very detailed report was given by John G. Utz as chairman of the hard-working miscellaneous division. Considerable progress has been made toward recommending standards for license plate and holders, which subject is now in a very chaotic condition, since the legislature of each State has followed its separate whim in the matter of the size and shape of licenses.

The committee is not attempting to fix a standard for the size of the plate, but believes it is possible to reach a standard on the location of the four holes for attaching which will be acceptable to all the States. Fig. 3 shows the location of these holes in both license pads and in the holders for attaching them to the front and rear of the cars. For the rear bracket, the committee believes that a central light placed at the top of the pad is the most feasible and most efficient.

In relation to this subject, the division has made a study not only of the license plate in use throughout the country but also of legibility. In this regard the report goes quite fully into the standard tests of opticians and gives some interesting data showing that characters 3 in. high with ½-in. strokes can be used for car numbers with the best results:

Miscellaneous Division

At a meeting held in Detroit on Oct. 8 the work of the July meeting of the miscellaneous division was reviewed, and some slight changes made under each head. The following minutes therefore summarize the entire work of the division since the June meeting of the society:

License Plates

It is proposed to standardize the location of four holes for attaching license plates to their supporting brackets. These holes to be located symmetrically with respect to the vertical center line of the plate, and preferably also with the horizontal center line. The horizontal distance between hole centers is to be 7 in. and the vertical distance from 3½ to 5 in. Holes are to be ¼ in. in diameter, and located on centers preferably ½, not over ⅝ in. from the upper and lower edges of the plate. The horizontal distance was changed from 8 to 7 in., because wide brackets often cause interference with radiator studs, and to accommodate the few extra short tags.

Discussion of the size and number of characters required brought out the suggestion that one prefix letter with four digits provided characters for 200,000 cars, without using letters like I, O, C. G and Q, which might cause confusion. This will probably be a sufficient number for any state for some time yet, and it is more easily read, as well as shorter, than a number with six digits.

Figures 4 in. in height are used by many states, the height being often specified by law. In order to get the long numbers on a plate of reasonable length it has been found necessary in many instances to crowd the digits both as to width and spacing. It is thought that characters 3 in. in height, with strokes of ½ in. and at least the same amount of opening between strokes and space between letters, will make numbers which can be read at fully as great a distance.

A careful statement of the reasons for adopting the standard as suggested has been prepared for the purpose of influencing state officials and legislatures, probably through the various automobile clubs, to adopt license plates in accordance with the proposed standard. Another statement has been prepared concerning brackets for supporting these tags, for circulation among motor car manufacturers.

Makers' Number Location Recommended

At present the finding of the makers' identification number is very liable to be a wild-goose chase as there now is no uniformity as to its location. The National Automobile Chamber of Commerce, Inc., has brought this matter to the society's attention and the miscellaneous division recommends that the number for the car shall be placed on the outside flap of the right frame member as far forward as possible and stamped in in letters ¼ in. high.

The division wishes to discourage the use of plates instead of letters stamped into the frame because of the ease with which these plates may be lost on old cars. Of equal importance to owners, dealers and police department is the location of the motor number, and the division recommends that this mark be stamped on the top of the crankcase as far forward and as near the middle as possible. The recommendation was made as follows:

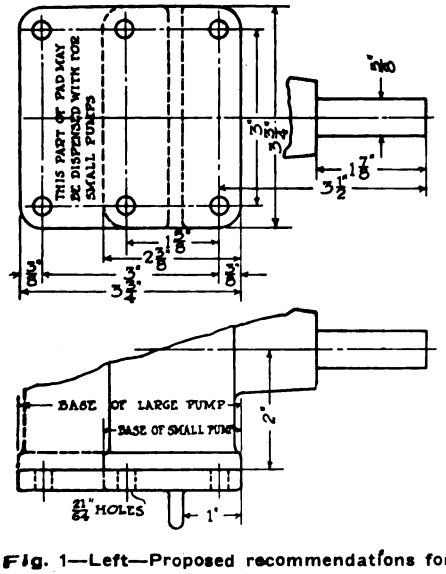
Location of Makers' Identification Number

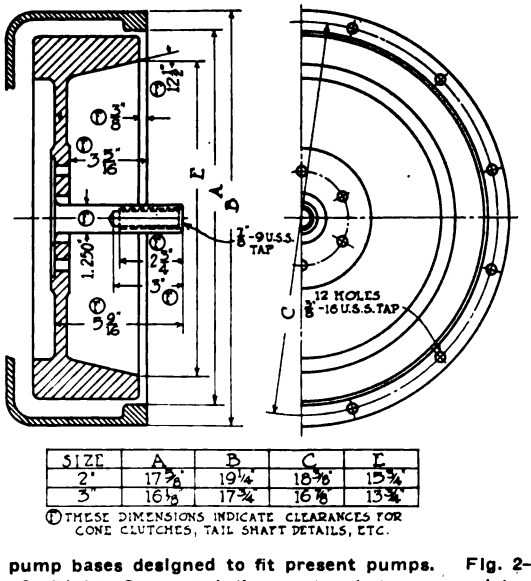
It is recommended that the standard location for the car, chassis, or frame number (whichever is used for identification) shall be on the outside flat of the right hand frame member as far forward as possible; and that such number shall be heavily indented in the frame side member in characters not less than ¼ in. high Where this location is inaccessible, it should be approximated.

The use of attached plates in lieu of numbers stamped as specified is discouraged by the division, because of the ease with which a plate can be removed.

Location of Motor Number

It is recommended that the standard location for the motor num-





SIZE	A	B	C	E
2"	17⅞"	19¼"	18⅞"	15¾"
3"	16½"	17¾"	16⅞"	13¾"

① THESE DIMENSIONS INDICATE CLEARANCES FOR CONE CLUTCHES, TAIL SHAFT DETAILS, ETC.

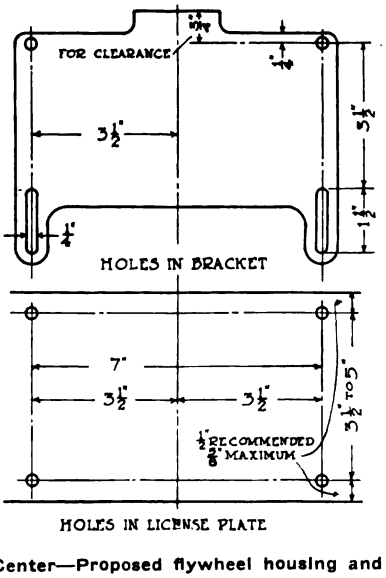


Fig. 1—Left—Proposed recommendations for pump bases designed to fit present pumps. Fig. 2—Center—Proposed flywheel housing and cone clutch details. Fig. 3—Right—Suggested license bracket proposed by miscellaneous division

ber be on the crankcase proper, as far forward, on top, and as near the middle as practical crosswise, preference being given to the right side. Consideration should be given to accessibility in the completely assembled car. The number should be deeply indented in the crankcase in characters at least ¼ in. high.

In stating the weight of the car, the division specifies that this shall mean the actual scale weight of the car complete with catalog equipment less fuel and water.

Standard Weight of Car

It is recommended that the S. A. E. standard weight of a car shall be the actual scale weight of the car with complete catalog equipment, less fuel and water.

Tire Pump Base Recommended

Once before the subject of tire pumps has received the consideration of the committee, but the standards developed at that time became obsolete with the changes made at the time that starting and lighting equipment was added by the manufacturers. Recommendations now made are for standardizing the bases and location of holes in same rather than standard dimensions for the mechanical tire pumps themselves. Fig. 1, shows the proposed recommendations, and it is stated that although this base or pad does not exactly conform to any one pump on the market it has been laid out so that it will carry any design now made. In some cases, however, an adapter plate must be used in fitting a pump to such a base. The recommendation was as follows:

Tire Pump Bases

It is recommended that engines be fitted with pads for tire pumps 3¾ in. square, having six 21/64 in. holes located as shown in the accompanying sketch. If a rib is used at the under side of the pad it should be located as shown.

It is recommended that tire pumps be made to conform to four of the six holes, using two on each side of the location shown for the rib. Shaft height is to be 2 in. and total projection of the shaft is to be 3½ in. from the center line of the nearest pair of holes in the base. The exposed end of the shaft is to be 1⅞ in. in length and ⅝ in. in diameter.

These matters of license plate, car and motor numbers, weights and tire pump basis were all accepted by the committee for presentation and action at the next meeting of the society in January.

Miscellaneous Division Progress

Progress was also reported by the miscellaneous division on the subject of piston rings, hose and hose clamps and speedometer drive connections. Screws for cowl boards were before the section but it appears that all the cowl fastenings are to be out of sight on the new cars and it is probable therefore that this subject will be dropped. The matter of specifications for hydrocarbons will be referred to a special committee having expert knowledge on the subject. Specifications for clutch facing and V-belt and pulleys for fan will probably be referred to the new motor and transmission committee. The matter of thread tolerances is awaiting the action of the American Society of Mechanical Engineers in order to save a possible duplication of work in this regard. There was no discussion.

Progress reports were given for the international standards ball and roller bearing, pleasure car wheels, and research division. The propaganda for an international standard for solid tire sizes is receiving very favorable support, and it is expected that our government, the British consular service and the British trade organizations will all lend aid to the formation of such a standard.

Work on Taper Roller Bearing Eyes

At present the ball and roller bearing division is gathering data looking to the standardization of taper roller bearing sizes and although it will be several years before all parties are able to come to an agreement on the subject, a standard in this direction looks hopeful at this time. Besides the investigation relative to tap drill sizes the research division has recently been assigned work of developing a standard method of carrying out acceleration tests.

In the report of the truck standards committee W. P. Kennedy said that his section had voted against the branding of solid tires with their equivalent millimeter dimensions. The section, however, is developing a table for the S. A. E. hand book which will give a conversion between the American and European sizes of tires. The addition of a 32-in. truck wheel has been suggested to the division for use on small, cheap cars, but as no special demand seems to have arisen for this size the committee men do not believe it is advisable to add it to the standard. In relation to industrial truck sizes, the division feels that due to the unsettled practice in this field, it is only warranted in recommending standards for wheel diameters which are as follows: 10, 16, 20, 22 and 27 in.

Another of the very complete reports submitted was that of the automobile spring division which was presented by W. M. Newkirk in the absence of Chairman McKinley. This report dealt largely with notes on the basis of purchase and the chemical and physical tests to be given by buyers of springs. Sketches were submitted showing the proposed method of making tests upon the different classes of springs which will be presented to the society in January.

The proposed tentative specifications for automobile springs appear below:

Basis of Purchase

1—(a) These specifications cover all leaf springs for automobiles.

(b) Springs shall be made of carbon steel bars, conforming to the requirements of the Standard S. A. E. Specification No. 1095 for Carbon-Steel bars, unless alloy steel bars are specified by the purchaser.

(c) When alloy steel bars are specified, the manufacturer and the purchaser shall agree upon the type and grade of the bars, which shall conform to the Standard S. A. E. Specifications for Silico-Manganese-Steel bars, No. 9250 or 9260, or to the specifications for Chrome-Vanadium-Steel bars No. 6145 or 6150.

(d) Other steels shall be a matter of agreement between purchaser and manufacturer.

SEC. I. CHEMICAL PROPERTIES AND TESTS

Check Analyses

2—(a) A check analysis may be made by the purchaser of each size of spring steel bars involved. This analysis shall conform to the requirements specified in Section 1 (b), (c) or (d).

(b) In case samples for analysis from finished springs are required, such samples shall be taken from the unworked (referring to hot work) portion of the plates and shall represent the full cross-section after rejecting any decarbonized material.

SEC. II. INSPECTION, PHYSICAL TESTS AND REQUIREMENTS OF ELLIPTIC SPRINGS

Workmanship

3—(a) The purchaser or his representative may examine all springs in each lot for workmanship, general dimensions and capacity.

(b) The springs shall be submitted for inspection complete, in the condition required by the drawings and shall conform to such drawings, within the variations allowed by these specifications. Dimensions which affect the contour only and do not affect the interchange or service of the springs need only be approximate.

(c) The springs shall have the leaves uniformly graduated in length, properly bent, and fitted reasonably true to curves given in the drawings.

Test Springs

4—(a) From each lot of springs which has met the requirements of Section 3, the purchaser or his representative may select for physical tests, at least 25 per cent, to be tested preferably in accordance with the "Compression" Method of Section 6.

(b) If any of the springs representing a lot fail to meet the requirements as to physical properties specified in Section 6 or Section 7 as required, but at least half of the springs representing a lot do meet these requirements, each spring shall be tested and those which meet the requirements, shall be accepted. If more than half of the springs representing a lot fail to meet the requirements as to physical properties specified in Section 6 or Section 7 as required, the lot represented may be rejected. The number representing the lot must be at least 25 per cent of the lot.

Method of Support and Measuring

5—(a) Full elliptic springs shall be tested in the upright position, while one-quarter elliptic, half-elliptic, three-quarter elliptic, and cantilever springs are to be tested in the inverted position and must be so supported as to give free lateral movement on compression.

(b) The anvil or pressure block of the testing machine shall be formed to sketch shown.

(c) Unless otherwise specified, all measurements of height are to be made as follows: In half-elliptic springs, between the surface of the pressure block and a line joining the centers of the eyes; in full and three-quarter elliptics, between the surfaces of the upper and lower pressure blocks; in one-quarter elliptics, between the center of the eye, and the supporting pad of the spring, measured at right angles to the surface of the latter.

Compression Method

6—(a) Free Height:—The spring shall be placed in the testing machine, as specified in Section 5 and a test load of 150 per cent of the specified working load shall be applied (provided the deflection corresponding to this load does not exceed the maximum possible on the car, in which case the load corresponding to maximum deflection shall be used), then fully released and the height measured. This shall be known as the "free height."

(b) Loaded Height—The specified working load shall then be gradually applied and the height measured without rapping or

otherwise disturbing the spring. This shall be known as the "loaded height" and in the case of pleasure cars shall not be less but may be ¼ and ⅜ more than that specified for front and rear springs respectively.

Note: Loading Precautions—Should the specified working load be accidentally exceeded in conducting the test for loaded height, the measurement of height should not be made after merely releasing the load to the specified figure but the load should be removed to not over one-half the specified working load, after which it is to be again brought up to the specified figure at which measurements are to be made.

(c) Permanent Set—When the loaded height has been determined the spring shall be fully released and then its height at 75 per cent of the rated load measured as in the previous method. Following this the spring shall be compressed to 200 per cent of its rated load or to limit of possible deflection on the car, fully released and the 75 per cent load again applied and the height of the spring again measured. Any difference between the first and last heights thus found is the permanent set and this shall not exceed 1/16 in. If there is a permanent set which does not exceed 1/16 in., the spring shall be loaded twice to 200 per cent of the specified working load or to limit of possible deflection on the car, released, and the permanent set again measured. There shall be no increase in the permanent set.

Rate per Inch or Flexibility

7—(a) When the rate per inch, or the flexibility is specified, this should be given in pounds per inch. This should be determined by taking the height at 75 per cent of the rated load and at 125 per cent of the rated load and by dividing the difference in load by the difference in height, the resulting figure gives the average rate in pounds per inch, or flexibility.

This figure shall not vary from that specified more than 5 per cent plus or minus.

Reworking

8—Any springs which fail to meet the requirements of these specifications as to dimensions or tests may be again submitted after being remade by the manufacturer, such remaking to consist of insertion of new leaves or of annealing, reforming, and retreating of old leaves. No springs shall contain cold reworked leaves.

SEC. III. MARKING

Marking

9—(a) The name or brand of the manufacturer, the year and month of manufacture, and if specified, the purchaser's class or grade number, shall be legibly stamped on each spring at a place not detrimental to the life or service of the spring.

(b) Any stamping by the inspector shall be so placed as not to be detrimental to the life or service of the spring.

SEC. IV. INSPECTION AND REJECTION

Inspection

10—The inspector representing the purchaser shall have free entry at all times while work on the contract of the purchaser is being performed, to all parts of the manufacturer's works which concern the manufacture of the springs ordered. The manufacturer shall afford the inspector, free of cost, all reasonable facilities to satisfy him that the springs are being furnished in accordance with these specifications. All tests (except check analyses) and inspection shall be made at the place of manufacture prior to shipment, unless otherwise specified, and shall be so conducted as not to interfere unnecessarily with the operation of the works.

Rejection

11—Unless otherwise specified, any rejection based on tests made in accordance with Section II, shall be reported within a reasonable time from the receipt of samples.

Rehearing

12—In case of dissatisfaction with the results of the test, the spring manufacturer may make claim for a rehearing within two weeks. Samples tested in accordance with Section II, which represent rejected springs, shall be preserved for this length of time.

Report of Electrical Equipment Division

The report of the electrical equipment division was made by W. H. Conant, chairman. He stated that at the last meeting the division took up the work of establishing the standard sizes of wire for motor cars in the endeavor to select four sizes for starter motors and three separate sizes for generator and lighting equipment. The division is deferring the make-up of the wire and is not submitting recommendations on that at the present time.

It has appointed a sub-committee on insulation so that it will be possible to specify by number or letter the exact installation size as well as the exact size of the wire and later perhaps the make-up or stranding of the wire. The sub-committee also is reporting on uniform tests for wires to check up the specifications as provided by the Railway Signal Association and the Institute of Electrical Engineers. On the subject of bulbs and bases it was found that most manufacturers booked their favor on the S. A. E. recommended practice.

It was decided by the division to attempt to standardize the application of starting motors; also to proceed with the matter of wire installation.

Glare Remedy Is Improved Design

In presenting the findings of the division on the subject of headlight glare, Chairman Conant touched on a point of wide interest to motorists, accessory men and manufacturers. He stated that the division was convinced that there was no such thing as a successful dimming device, that the only remedy for headlight glare was to improve the focusing of light, to improve the sockets, reflectors and the lenses and properly to standardize the height and tilting angle of the lamp; that is, that the beam of light should strike the ground at a certain distance in front of the car and should be of a certain width.

In dilating on this it was stated that the division did not recommend dimming devices; that the root of the solution was so arranged in the lamp that the rays be projected forward in a parallel beam and not as a cone. This was a progress report only.

Visit Standard Oil Refineries

After a vote of thanks to the Chicago Automobile Club for hospitality to the standards committee meeting the standards committee returned to accept the invitation of Mark A. Smith of the Standard Oil Co., to go through the refineries at Whiting, where they watched the transformation of crude oil into high-test gasoline, lubricating oils, greases, benzol, medicine and even wax candles.

Standards committee of the Society of Automobile Engineers inspecting the refineries of the Standard Oil Co. at Whiting, Ind.

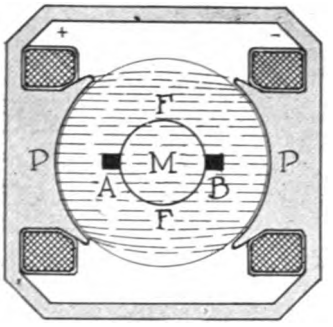

Fig. 1—Position of brushes AB for drawing maximum current from armature M. P are the poles of the generator and F the magnetic field In this position the brushes connect that particular wire in the armature which is cutting or crossing the magnetic field at the maximum speed. The true state of affairs is a little different as field is never parallel.

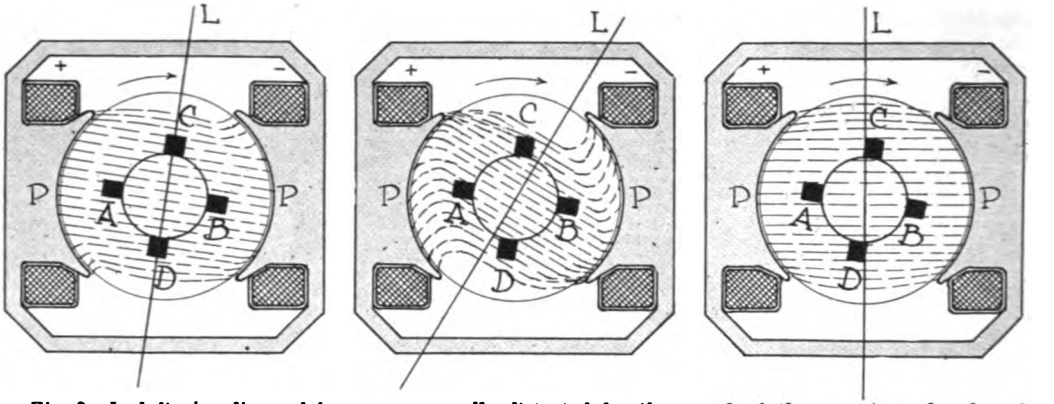

Fig. 2—In left view lines of force are normally distorted by the speed of the armature, brushes A and B are the main brushes and are drawing full current since they are at right angles to the lines of force. C and D being parallel with the lines are at zero potential and no current passes between. Center. Field is more distorted by greater speed of armature so that middle or neutral line of field L is moved so that brushes C and D come to left and right of it. Then current will flow from C to D say, but it will be smaller than the current between A and B because the brushes are closer to the neutral line. Right. Armature has slowed down till distortion has gone from field; which brings neutral line L to left of brush C. Then current will flow from D to C while the direction of flow between A and B remains unchanged, since neither A nor B has passed the neutral line L. This action is just as though the left and right sides of the dynamo were plus and minus, the dividing line being the neutral line of the field. Any brush to the left is plus and any brush to the right is minus say, while on the line is neither plus nor minus but simply zero

Automobile Electricity

The Theory and Practice of Different Lighting, Starting and Ignition Systems Explained and Considered

By A. Ludlow Clayden

IN the early days of motoring it was necessary for a driver to be more than a little of an electrician. Then came a time when, thanks to the perfection of the magneto, electricity seemed a thing of the past and one might forget that there was such a thing as a spark in the makeup of a chassis. Again, times changed and the storage battery erstwhile losing in favor, returned to service, and dynamos, motors, fuses and cutouts returned to worry the engineer and occasionally to perturb the user of a car.

We have been and are still in a period of transition, for the automobile of today is certainly as little like the car of 1920 as it bears resemblance to the car of 1910. What way the coming development will trend no man living can foretell, but it is safe to assume that electricity, which now takes a part in the daily life of every civilized man, is far more likely to strengthen its grip upon the gasoline automobile than it is to loosen the grasp it has already. If this be true, and there is little doubt of it, then it is important that every engineer and every user of a car who aspires to get the best service from it should see to it that his understanding of electrical development is thorough.

The magneto displaced dry cell or battery ignition not because it was simpler—for it is vastly more complicated—but because it was more reliable and *less trouble to look after;* similarly the electric lighting outfit came into favor because it was less trouble than gas lamps. Having the dynamo and the battery for lighting it was natural evolution to add the cranking motor, and then to eliminate the magneto which was no longer essential with an ever-charged storage battery at hand. Furthermore, the lessons taught by the magneto as to the construction of high and low-tension current distributing apparatus were not lost upon the present-day manufacturers of ignition timers, so that the modern equipment combines the mechanical excellence of the magneto with the electrical simplicity of a battery system.

The Return of the Timer

In changing from magneto back to battery and coil—even though these units may be, and are, of a vastly improved character—we lose one thing only, and this is the natural tendency for the magneto spark to intensify as the speed rises. The natural advance of ignition point, the greater heat of the discharge at high speed and the absence of mechanical parts to produce this result are the outstanding advantages of the magneto. Automatic advancing timers, and timers which cause the contact at high speed to be of longer relative duration, can overcome the natural shortcom-

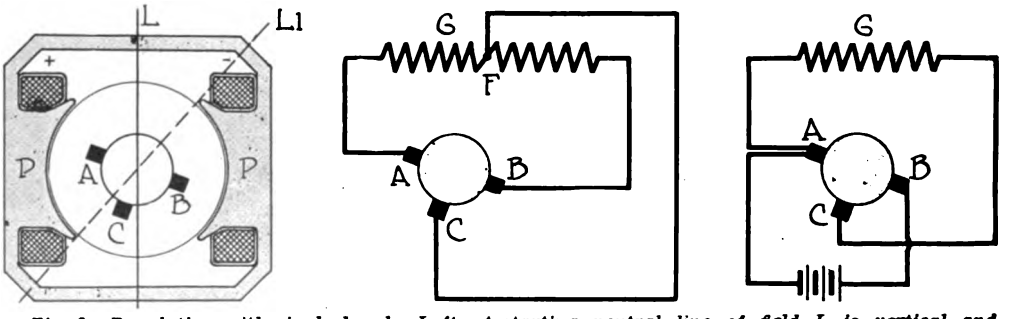

Fig. 3—Regulation with single brush. Left, at starting neutral line of field L is vertical and brushes A and C are to left of it on plus side while brush B is alone on minus side. When speed increases neutral line L first comes into line with C so that the third brush becomes inoperative, and when speed is still higher line L comes into the dotted position. Then C is on minus side and current from it tries to flow back to A instead of to B. Right—Connections for system. As long as C is plus current flows from F to B along with current flowing from A to B. As soon as C is minus its current tries to flow back to A. G is the field coil or shunt winding of the pole pieces

ings of battery ignition, so it is reasonable to suppose that the day is not far off when electrical knowledge will have reached a point which will allow of complete modification of the magneto *as we know it to-day*. It may be some time before everyone is satisfied that the day is here, but come it must sooner or later.

In considering the necessary output for the dynamo we have to remember that it has:

To furnish enough current to serve the ignition.

To provide enough electrical energy to light the lamps for a reasonable average length of time per 100 miles run.

To give the maximum possible output for the minimum possible weight.

To absorb the minimum possible power to drive.

The last two requisites mean that the current must be of a character that best suits the conditions of battery charging, that the dynamo must be operative over the widest possible range of engine speed and that the electrical and mechanical detail must be of the highest class.

There are a variety of things which make the electrician's task especially hard. First, the machine has to be able to withstand a great amount of abuse, it has to be fool proof in the most literal sense of the term.

Secondly, the machine has to be able to bear extremely high rates of revolution, extreme variations of temperature and excessive vibration or shock.

Thirdly, it is necessary to introduce some means of keeping the voltage constant at armature speeds from something like 1,000 to nearly 10,000 r.p.m.

Lastly, these, and a variety of lesser conditions, must be observed and provided for effectually at a minimum of cost.

There is as much difference between designing a dynamo to run in a power station and a generator for an automobile as there is between a gas engine for stationary service and an automobile motor. That the trade has risen so nobly to the demand is positively wonderful, that the generators in common use are so good is little less than a miracle and redounds to the credit of those who have been responsible for the development.

Methods of Control

Descending (for a moment only) into elementary electric theory, a definite voltage will drive different amounts of current through different circuits, according to the resistance thereof. Suppose we have two terminals like the terminals of a dynamo that is running at a constant speed, and suppose we connect two different circuits to those terminals, the circuit with the smaller resistance will take a current greater than that passed through the circuit of greater resistance; the currents will be in inverse proportion to the resistances. This is expressed by the law that the current in amperes flowing through a circuit is always equal to the voltage, divided by the resistance of the circuit measured in ohms.

In an electrical system for automobile lighting we are bound to have a practically constant voltage in the main circuit because the lamps will operate only within narrow limits of voltage. But we need different amounts of *energy* according to the state of affairs at the moment. Electrical energy is the product of the voltage and current. Suppose that we have only the small lamps in use, we need a definite voltage but only a small current, but if we now switch in the large lamps we need more current at the same voltage. Again, if the battery is low we need current to bring it back to the fully charged state, and the nearer it approaches to the fully charged condition the less current do we need. This means that the *energy* demand on a car is always fluctuating while the voltage demand is constant.

If we have a generator with constant voltage regulation and constant current regulation also, it means that however fast we drive it, the energy given out cannot exceed a definite amount. If there is no regulation of current it is possible to increase the output in watts of electrical energy to meet the conditions of the moment. In some systems there is a good deal of energy wasted by conversion into heat—the output is kept down by the absorption of part of the current. In others the power used to drive the generator is more or less directly proportional to the current being used. There are reasons for and against each system, for the power used to drive the generator is so small that a little wastage is worth while if we obtain some other advantage such as simplicity of construction.

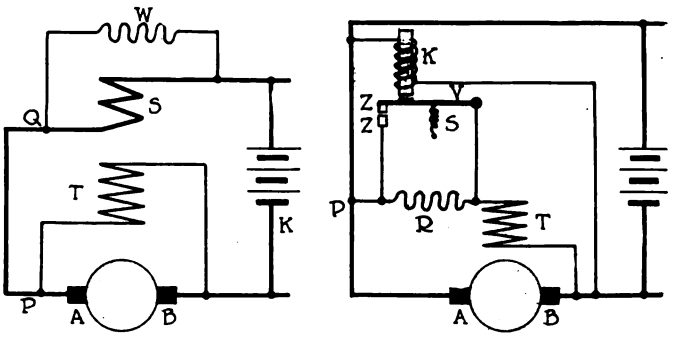

Fig. 4—Left—Bucking Coil Regulation. Current flows from A through the shunt coil T and so back to B all the time. Also some of the current divides at point P and goes through the opposing series coil S and thence to the battery, through the latter and back to B that way. But the current which takes this circuit has also a choice of routes at Q; it can go through the iron wire W as well as the series coil S. The greater the current the hotter does the iron wire get and the less current will it pass, so more and more goes through the series coil S, so acting against the magnetism due to the shunt coil T and preventing the field magnets from becoming too strong

Fig. 5—Right—Vibrator Voltage Control. T is the shunt coil of the field magnets. Current from A flows round the outer circuit through the battery and divides at P, part going through the shunt winding. Also there is a branch across the outer circuit through the little coil K. There is a spring reed V, which is pulled down by a little spring S so that the two contact pieces ZZ come together and then current flows from P to Z and thence through T back to B. When the current through K is strong enough this pulls apart the contacts Z, forcing current to go from P through the resistance R and so to T. This cuts down the current in T by reason of the resistance of R, the voltage drops and K lets go of V. Whereupon voltage rises again and the process is repeated thousands of times every minute

It is necessary to remember that a fixed voltage delivers a current in inverse proportion to the resistance of the circuit. This means that if the regulating resistance is part of the *main* circuit it regulates the current available for battery charging as well as regulating the exciting current in the field coils. If, on the other hand, the regulating resistance is interposed simply in the *shunt* circuit the current flow in the main circuit depends upon the resistance therein, and upon nothing else.

Of course there is no such thing as an absolutely constant current generator or an absolutely constant voltage one either; both vary a little as speed rises and falls, but the best machines approximate closely to fixed values.

However a generator has its field coils wound the voltage will increase as the speed of the armature rises, as long as conditions in the outer circuit remain unchanged. Our ideal for automobile work is a machine which will produce a voltage of unvarying degree and an amount of current to suit the demand of the moment.

The first idea was to do this by means of a mechanical governor which would prevent any current from flowing till the dynamo was running fast enough to give the desired potential, and then to keep it at just that speed whatever the speed of the engine. This scheme seemed to have the merit of simplicity, but it soon showed the demerit of susceptibility to wear, dirt and maladjustment.

Meanwhile a kindred problem that had engaged the attention of electrical engineers was the lighting of railroad trains and a type of dynamo which became popular for this purpose was the third brush regulator. This was soon taken up for automobile purposes and is still largely used.

If we put the brushes in such a position that they are in line with the lines of the magnetic field as in Fig. 1 we shall obtain the maximum current, but if we shift them round, the voltage difference will drop to nothing when they are at right angles to the original position, and in line with the magnetic lines of force. At any intermediate position the difference of potential between the brushes is in proportion to the angle they make with the inoperative position—the angle they make with the magnetic lines of force, that is.

Suppose now that we use four brushes on a two-pole dynamo and set a pair to give us the maximum current, then a pair placed in any other position relative to the armature will give a smaller current. By causing the excitation of the field magnets by a shunt winding between the main brushes we shall have too strong a field at high speeds and too weak a field at low rates of revolution. Just as the current at the main brushes rises and falls, so will the current at the subsidiary brushes; and, if we connect the latter by a magnet winding which *opposes* the main shunt winding, we can cause the excitation of the magnets actually to be reduced as the speed goes up.

There is another thing which helps us in this system of regulation; namely magnetic lag. The armature tends to drag the magnetic field after it, so the lines of force instead of passing straight from pole to pole really lie diagonally. The higher the armature speed the more are the lines of force pulled out of straight. But the maximum current is still to be had when the brushes are at right angles to the lines of force, for which reason the brushes are usually set a little "retarded" and not at right angles to the pole pieces.

This shifting of the magnetic field has a profound effect upon the current in the subsidiary circuit. Suppose we set the auxiliary brushes so that—at normal speed—they are at the position of no difference of potential; see diagrams in Fig. 2. If the speed falls off the lines of magnetic force will come more nearly into line with the pole pieces and a current will flow from, let us say, brush C to brush D. If on the other hand, the speed increases, so that the magnetic field becomes more instead of less distorted, then the lines of force will cross the line joining the two brushes in the opposite direction. It is easy to see that this is equivalent to moving the brushes across the field and so *past* the position of no current. The effect will be to start a fresh current between the brushes but it will now flow from D to C.

In short, we can adjust the position of the subsidiary brushes so that the current between them will reverse its direction at any desired speed of armature revolution.

This means that if the subsidiary brushes feed a coil wound around the field magnets the current will first try to magnetize them so that the left—say—is a north pole and the right a south pole. As speed goes up, the current will decrease till it is nothing at all, and then it will flow backwards, tending to make the left pole piece a south pole and the other a north. But all this time we have the current from the main brushes flowing around the shunt winding in a constant direction, trying all the while to make the left pole of north magnetism and the right of south. Therefore, the current from the auxiliary brushes first helps that from the main brushes, and then, after a certain armature speed is passed, it *opposes* the main shunt winding. Of the two, the latter is always the stronger, so that the polarity of the machine does not change, and the windings are proportioned to keep the excitation at such a pitch that the voltage remains practically constant.

There is an ingenious way in which the fourth brush can be dispensed with, by connecting a third brush in the middle of the main shunt winding. The potential of this brush will decrease, reverse, and then increase again exactly as though the second subsidiary brush was opposite to it. This means that if current flows from A to B when the armature is running slowly, the current from C flows through half the shunt coil to B and helps the main brushes. When the polarity of the brush C is reversed, current from it tries to flow back to A against the current coming from A to B. This weakens the A to B current and so weakens the field; just as in the four brush machine, we can set the neutral speed by adjusting the brush C moving it a little one way or the other around the commutator. This is shown in Fig. 3.

Another method is to wind the magnets with a plain shunt coil between A and C which leaves B unconnected with the field winding. Of course, current between A and C varies with the changing potential of the brush C. This method is usually preferable to the original scheme of a divided field coil described above.

Bucking Coil Regulation

In order to maintain a constant voltage at the main terminals of the dynamo there are two things which must be controlled in proportion, namely the speed of the armature and the density of the field. The determining factor in voltage is the number of magnetic lines cut by the armature coils per unit of time. If the armature speeds up we can prevent voltage rise by reducing the strength of the field, and if the armature slows we can keep up the voltage by increasing the field density.

Now, the mechanical attempts to make the armature speed constant so that the field might be kept constant too were not successful, and the next step was to let the armature speed vary as in the engine speed and to introduce purely electrical means to vary the strength of the field magnets, reducing this steadily as the speed rose. One of the most popular ways of doing this (apart from the extra brush systems just described) is to arrange the shunt coils of the field magnets so that they are supplied with current from the *battery* and not directly from the armature. This gives a practically constant field such as we could get from a permanent magnet.

Having this constant field we need means for reducing its strength as the armature speed goes up, and to provide this a separate coil is wound on the fields of the opposite hand to the shunt coils, so that current flowing through it will oppose the magnetism induced by the shunt circuit. At low speeds we desire very little current in this series coil and at high speeds a good deal thereof. To vary the current in the series coil a short coil of iron wire (without any core) is connected in the circuit so that the current from the brushes has a choice of paths; it can go through the series coil or through the iron wire. When the total amount of current is small the resistance of the iron wire is low, as it is quite cold, but, if the current rises, the iron wire heats up instantly and offers a very high resistance indeed. Since the iron wire and the series coil are alternative circuits, and since the resistance of the series coil does not vary, it follows that any rise in resistance of the iron wire will cause more current to be sent through the series coil. We already know that the greater the current in the series coil the greater the opposition to the magnetizing action of the shunt coil, so by proportioning the iron wire to suit the conditions it is possble to keep the current output of the dynamo practically constant.

The voltage in this system is controlled by the battery, which means that the generator and battery together make up the supply station from which current is taken for the lamps. This point must be grasped because some other systems are different, having constant *voltage* generators instead of constant *current* machines.

Voltage Regulation by Vibrator

The most recent scheme for regulating output is to use a plain shunt winding and no auxiliary coils, but to have an external resistance that can be put into circuit with, or withdrawn from the shunt coils. This causes the excitation to vary. Now, if the current in the shunt coils varies

rapidly, the excitation will be that due to the average current. Thus, if we have a plain shunt winding and constantly put resistance into it and then take it out again, the excitation will be equivalent to the average current flowing in the coils. In the vibrator control there is a spring steel reed carrying contacts that either add the resistance to the shunt coils or take it out again. This reed is controlled by a small magnet that is a separate shunt circuit of its own—merely a bridge across the brushes, the resistance, of course, being high so that the current flow is small. The current in this branch will vary with the voltage at the brushes, so when this rises to a determined value the reed will be pulled down, and the resistance thus put into the shunt winding. The effect is to reduce the current in the shunt, to reduce the excitation and so to reduce the voltage at the brushes. As soon as this has dropped sufficiently, the little magnet lets go of the reed and the resistance is taken out of the shunt, the voltage rises again and in a small fraction of a second the resistance is again switched in. As a matter of fact the vibrator moves very rapidly, but its movement is uneven. If the armature speed is high the reed stays longer in the attracted position, when the resistance is *in* the shunt circuit, than it stays in the free position, when the resistance is out. As armature speed falls the time for which the reed stays in the "resistance in" position gradually decreases until the resistance comes to be more out than in.

This means that the average current in the shunt is controlled so that the voltage at the brushes of the generator remains constant. It will be understood that the vibrating reed moves so fast that it cannot be seen holding onto one contact or the other; the action is very sensitive indeed and extremely rapid.

It is also possible to utilize this vibrator system to control the current rather than the voltage; to limit the possible maximum of ampere output, that is. To do this the little coil which is called K in Fig. 5 is put in the main circuit instead of in parallel with the brushes and battery as shown in Fig. 5. The action is to switch a resistance in and out of the shunt circuit just as before and so limit the magnetization of the generator, but the presence of the coil K in the main circuit limits the amount of *current* that can flow therein.

In succeeding articles it is hoped to deal with the principal systems now in use, describing them in detail. It will be found that each of them, and there are a good many, depend for the regulation of their output upon one or other of the broad principles herein described and explained, although the differences in detail are great.

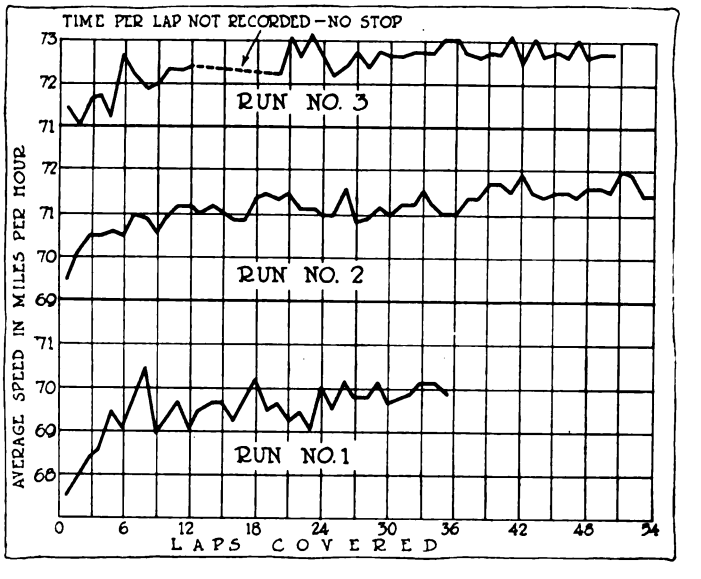
Cadillac 8 Averages 72.49 M. P. H. in A.C.A. Tests

NEW YORK CITY, Oct. 18—The technical committee of the Automobile Club of America has issued its report on the recently completed tests of two type 53 Cadillac eight-cylinder, seven-passenger cars. The object of the test was three-fold. First, to find what speed the car could maintain under varying conditions for a period of 1 hr. Second, what period of time would elapse while the car traveled 100 miles, and third, the gasoline and oil consumption measured for different rates of speed of the car.

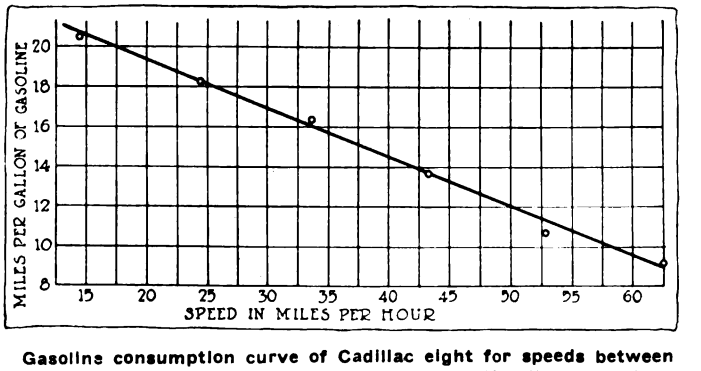
The runs for maximum speed were made on the Chicago Speedway, Sept. 21, and at Indianapolis, Oct. 5. Altogether there were four runs; first with the top and windshield, second, with the top and windshield down in both of which cases the car was driven by Philip Robertson; the third run was with the top and windshield down as in the second, but with W. J. Davidson driving. The fourth run was with the windshield and top up as in the first run with Sidney D. Waldon driving.

In the first run 70 miles were covered in 1 hr. and 25.4 sec. This is an average speed of 69.51 m.p.h. On the second run 72 miles were covered in 1 hr. and 47.4 sec., an average of 71.06 m.p.h. On the third run 100 miles were covered in 1 hr., 22 min., 46 sec., an average speed of 72.49 m.p.h., and on the fourth run to determine the miles per gallon of gasoline, the result shown on the chart herewith was obtained. At the ordinary touring speed of 14.5 m.p.h. the consumption was 20.6 miles per gallon.

Both cars used were equipped with stock motors 3⅛ by 5⅛, eight-cylinder V. The gear ratio was 4 to 1, and the tires used 36 by 4½ Goodrich Silvertown with Rudge Whitworth wheels. Both cars had seven-passenger bodies and carried extra wheels. The fuel gave a Baumè reading of 60 at 60 deg. Fahr. On all the tests the cars averaged but small fuel consumption. At the high speeds of 71 and 69 m.p.h. the oil consumptions were 114 and 173.7 miles per gallon. On the fuel economy test the miles per gallon of oil were 675. Both cars were equipped with Hartford shock absorbers and were standard stock in every way except that the muffler plugs were removed during the Chicago tests for speed, but not during the gasoline consumption tests. The results are shown in the curves herewith.



Speed per lap of Cadillac eight on runs 1, with top and windshield up; 2, with top and windshield down; 3, with top and windshield down on 100-mile run. The average speeds for the three runs were: 69.51, 71.06 and 72.49 m.p.h. for 1, 2 and 3, respectively



Gasoline consumption curve of Cadillac eight for speeds between 15 and 60 m.p.h. At 20 m.p.h. the car traveled 19 miles per gallon. This about equals touring speed

The Engineers' Forum

Aluminum Piston Critics Answered—Fresh Views Advanced on Heat Conduction Argument and Inertia Study

By Joseph Leopold and James E. Diamond

EDITOR THE AUTOMOBILE:—With all due deference to the author of Prefers Iron or Steel, printed in your columns, I would call your attention to the following: In the first paragraph the author states: "The piston proper is heated by convection and radiation; this heat is carried off mainly by convection to the cylinder lubricating oil film and the rate of convection depends upon the maximum temperature within the cylinder and the piston speed. This heat is again carried by convection from the lubricating oil film to the cylinder wall and in turn carried by conduction through the cylinder wall proper and finally by convection to the cooling water. It then results that the conductivity of the material employed for the piston is not of material consequence."

Heat Conducted Through Piston

If heat is transmitted through the cylinder wall by means of conduction why is it not also transmitted through the piston walls by conduction? It is quite true that after the heat has been carried through the piston wall it will be transmitted through the air within the piston by convection into the "crankcase air." But if this operation is to take place rapidly, it stands to reason that the piston material must possess a high ratio of thermal conductivity. Also in the construction of aluminum pistons it is possible to employ ribbing under the head without adding any appreciable weight, which I believe tends to encourage heat radiation, and carry off the heat from the head, distributing same through the walls of the piston, when the operation of convection through the oil film, etc., will take place. I therefore fail to realize why "the conductivity of the material employed for the piston is not of material consequence."

With regard to inertia forces the author states: "I believe that automobile motors are ordinarily designed on the basis of an initial indicated pressure of about 350 lb. If this pressure is taken as the basis of construction, it is clear that the values of the inertia forces are of little moment until they exceed the indicator pressure."

To illustrate a variance of theory in this matter we may start with the piston's movement at the ending of the first half of the stroke. Here it will be seen that exhaustion has occurred and the only force acting on the piston (disregarding gas inlet which is very slight) is the inertia force. Now it is quite within reason to assume that in reversing the piston to operate on the second half of the stroke, it will be necessary to overcome the inertia force stored in the piston. And while no other element enters into the matter, inertia force depends entirely upon the weight of the object and the speed at which it is traveling. No doubt, such energy as may be accumulated in the piston during the upward or final strokes, will be of material benefit in overcoming the resistance of the gases and aiding the operation of compression. However, this advantage is greatly over-balanced by the fact that the inertia energy at the ending of the first half of the stroke is so much in excess of same. Also where a heavy piston is used the energy stored up in the piston is oftentimes so great that it is sufficient to overcome compression, therefore reversing the stresses on the connecting-rod bearings and subjecting the connecting-rod to tension. This theory can best be substantiated by actual practice, as I find that the majority of high speed motor manufacturers using iron pistons, find their crankpins worn principally on the inner side.

Practical Advantages Proved

To deviate from theory entirely and dwell on practice for a period, the advantage of aluminum pistons can best be demonstrated. The author states: "The writer has tried various aluminum alloy pistons in automobile, stationary and aeronautical motors, and in every case where a motor was operated at maximum power for long-continued periods failure resulted." This is surely in contrast to the results we have seen demonstrated. In the case of the speed boat Disturber IV., it will be admitted that the 750 hp. motor installed in this operated at maximum power for quite a period, also the Stutz car which holds the record for the fastest track time ever made by an American car in competition. The mere fact that many of the foremost and highest priced cars in this country are using aluminum alloy for piston construction, should be convincing evidence of their durability and efficiency, for a car which is sold at a price ranging from $5,000 to $8,000 could not afford to install inferior material.—JOSEPH LEOPOLD, Engineer, Walker M. Levett Co.

Considerations Overlooked

EDITOR THE AUTOMOBILE:—Relative to E. H. Sherbondy's contribution published in the Oct. 7 issue of THE AUTOMOBILE concerning the aluminum alloy piston, and in which an endeavor is made to minimize the importance of the properties of lightness and thermal conductivity on which all claims of superiority of advance for the alloy piston must rest, it is quite true that the piston receives, both by convection and radiation, its heat from the gases of combustion, and further that the temperature assumed by the piston will be a measure of the intensity of heat of the aforesaid gases.

It seems to me that one or two important considerations have been overlooked in analyzing the next steps. That the aluminum piston alloy has much greater thermal conductivity than iron seems not to be questioned. It should at once follow that the heat absorbed by the alloy piston head from the hot gases will be diffused throughout the entire piston mass in a much shorter time than would be the case with an iron piston. Consequently the temperature of the piston head will maintain a lower average, while the mean piston temperature will be higher than in an iron piston. As a matter of fact experiment has shown the correctness of this reasoning, disregarding entirely the exact process in the extraction of heat from the piston successively by oil film,

cylinder wall and water in the jacket. Is it not true that the more quickly the heat from the head may be conducted down throughout the skirt, the greater the opportunity the piston has to rid itself of much of its heat, since the further away from the piston head it is possible to conduct the heat, the greater the difference in temperature between the piston, and the surrounding media.

Condition of Heat Ideal

This being the case it seems to me that we have an ideal condition for heat extraction—two masses of widely different temperature in contact. No matter how brief the existence of this condition, there is going to be an approach toward equalization of temperature, which of course will be very much nearer that of the larger mass, the cylinder, etc., than the relatively small piston mass. If the much greater thermal conductivity of the aluminum piston alloy does not explain what follows I would be very glad to be set aright.

More evidence is available in connection with a 5-in. bore motor. The iron pistons with which this motor was originally equipped required a skirt clearance of 0.012 in., but Lynite pistons are now standard equipment on the job, and it has been found necessary to allow but 0.008 in. skirt clearance. In the other case a large number of Lynite pistons were sent out in motors, the clearances being exactly the same as those allowed for the standard iron ones. Absolutely no trouble due to seizure occurred except at very high motor speeds. In considering these cases it must be borne in mind that the expansion of aluminum is nearly twice that for iron, and for the same temperature range twice the expansion should be expected. Must not the greater thermal conductivity of the alloy explain this state of affairs? In this connection, too, I have recently learned of a case where, due to the fact that the head of the alloy piston always runs cooler than the iron one, it has been possible to increase the compression considerably without danger of preignition, whereas, when iron pistons were tried preignition invariably occurred.

Considering now the question of inertia, it is quite true that at low engine speeds this is negligible in comparison with the explosion load, but I do not believe that it is a negligible factor, by any means, at high engine speeds, and I believe the great majority of engineers are with me relative to this. Possibly even with the modern high speed, long stroke motor the inertia force is much less than the explosion load in the power stroke, but we have the power stroke with us for but one stroke, while we have the inertia forces throughout the entire cycle; that is, for the other three strokes. These inertia forces certainly must be productive of bearing pressure if nothing else, and should be comfortably missed. The fact that the Lynite piston has been standardized on, as widely as it has been, would seem to show that engineers do wish to eliminate, or rather reduce to the minimum, these inertia forces. Relative to what has been written concerning restricted valve capacity, what is the explanation for the increase in motor speed of a well known aeronautical motor from 1350 to 1450 r.p.m. by the substitution of Lynite pistons for the iron ones that formerly were standard, if the decrease of the inertia forces is not a factor? Similarly, the determining factor in the conclusion reached, to standardize on Lynite pistons instead of iron ones, by a very prominent manufacturer, was the fact that merely by the substitution of the alloy piston for the iron one, a difference of exactly 5 m.p.h., from 60 to 65 miles, in the speed of a new model was obtained.

One large manufacturer building fours, sixes and eights has standardized on Lynite pistons for his fours and eights, simply to reduce the vibration occasioned by the unbalanced forces attributable to inertia conditions. I certainly hold that this matter of inertia is no minor problem.

Regarding piston friction, Mr. Sherbondy points out the ideal condition, the existence of a perfect oil film. This is, in my own opinion, never attained, and the fact that pistons do show wear would, it seems to me, substantiate my opinion that there is metal to metal contact a goodly portion of the time. I still maintain that the mechanical efficiency of a motor will be higher with the alloy piston than with the iron one. We have done considerable experimenting relative to this matter of friction, and in spite of the fact that we have had every possible opportunity for maintaining a perfect oil film—an impossibility in the motor—there is a marked difference in the coefficient of friction measured by various combinations, iron on steel, aluminum on steel, etc.

Concerning strength is it not, after all, a question of sufficient strength, not maximum strength? Certainly sufficient strength, weight for weight, with the steel piston can be had with the Lynite piston alloy to answer the requirements of even the modern high duty motor, or rather the high duty motor that is forecast by Messrs. Porter and Sherbondy.

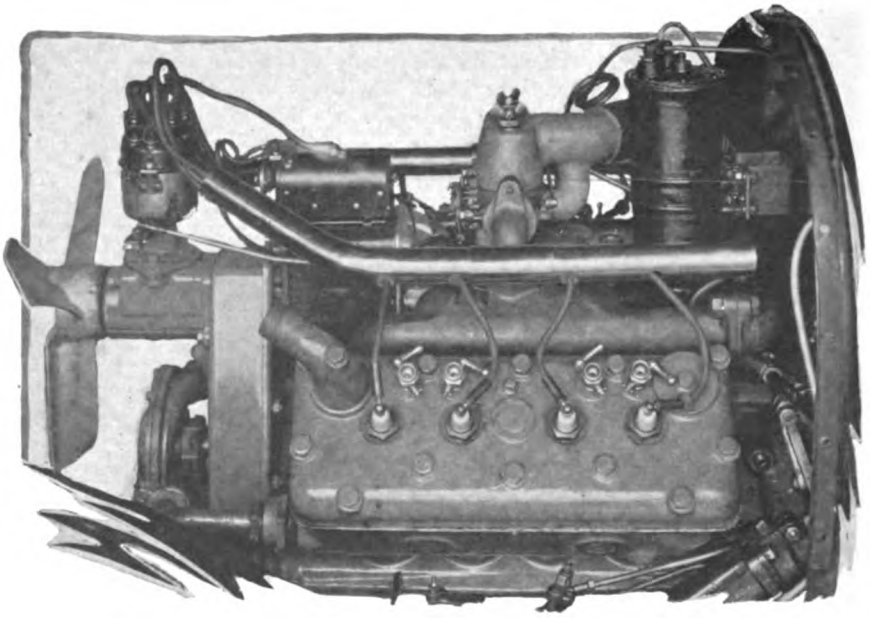
Possibly there are conditions in a two-cycle motor which do not exist in the four; my experience with two-cycle piston applications is exceedingly limited. In another contribution of mine published some few weeks since I stated that my company had in hand orders for a half million Lynite pistons. I take pleasure in advising that this number has increased to three quarters of a million.—JAMES E. DIAMOND, Engineer, Aluminum Castings Co.

The new Ward electric coupé exhibited at the electrical show in Grand Central Palace, New York City. This car sells for $1,295 and is fitted with a 4-5-passenger body with all the seats facing forward

Two-ton worm drive Wilson truck climbing Pike's Peak. It performed this feat four times within 6 days, and on three occasions with full capacity load

Oldsmobile Light 8 Is Ready

New Northway Motor Has Many Ingenious Features

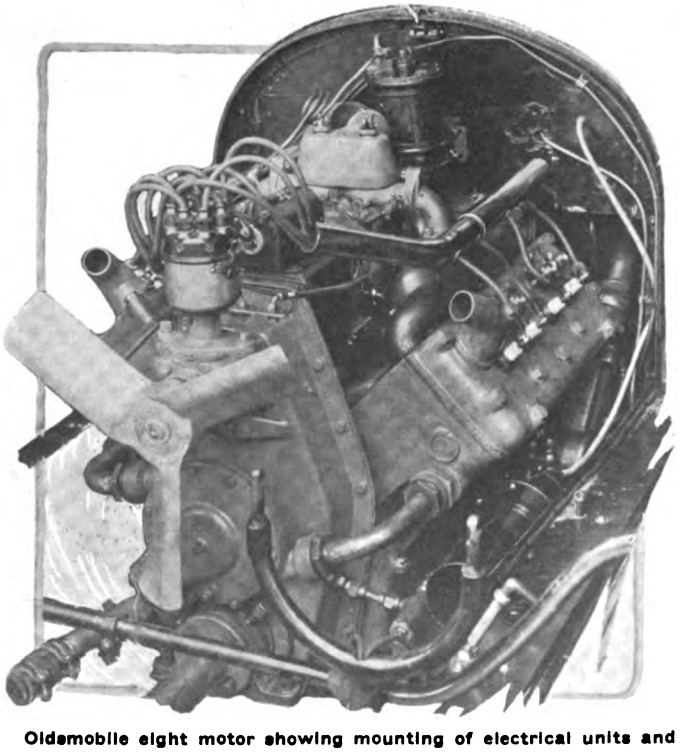


Left side of new Northway motor used in Oldsmobile light eight showing compactness of design. This motor is 2⅞ by 4¾ and although rated at 26.7 hp. it is claimed to develop 40 hp. on the brake at 1800 r.p.m.

AS has been announced briefly some months ago, the Olds Motor Works, Lansing, Mich., is now building an eight-cylinder model as a running mate for its four-cylinder car, a new type with much the same general body lines, and pronounced similarity in the mechanical construction to the four, but with its front end entirely different.

The price is $1,295, which in itself cannot but impress one as being extremely low for a car of the type. It is another instance of how the manufacturer is cutting the cost of production. Two or three years ago a car of the type at the price would have been regarded as nothing short of sensational, but to-day with all values appreciably on the up grade, the low price is less conspicuous, although the experienced man has only to examine the finish and general completeness of the job to realize that it has meant much careful planning and voluminous buying to make it possible.

Model 44, the new design, incorporates a V-type eight with cylinders 2⅞ by 4¾ in. 120 in., wheelbase, leather-faced cone clutch, floating axle, three-quarter elliptic springs, open drive shaft fitted with two universals and three-speed gearset. Thoughtful engineering has been applied in developing its ensemble. Rated at 26.7 hp. the engine is claimed to develop 40 hp. on the brake at 1800 r.p.m. It is a high-speed type with the maximum power at about 3300 r.p.m.



Oldsmobile eight motor showing mounting of electrical units and carbureter in the V. Note mounting of ignition distributer on timing gear case and Stewart vacuum fuel tank on dash

Materials entering into the construction of the power plant indicate a method to obtain maximum wearing qualities and utmost lightness. The aluminum pistons, having three cast-iron rings and one scraper ring, are relieved at the wrist-pin ends to prevent unevenness of piston expansion in the direction of the wrist-pin.

Externally the engine is very compact. Each cylinder group is integral with one-half of the crankcase, which is divided, not horizontally but vertically. The halves bolt together to give the complete engine, entirely inclosing the crankshaft with the exception of a bottom opening covered by a pan which forms the oil reservoir. The detachable cylinder heads carry the spark plugs, priming cocks and water-outlet connections.

The motor has a comparatively heavy crankshaft, supported on two bearings, a construction quite possible and feasible with a short motor where the balance is so well worked out. The main bearings are 2⅛ in. diameter and 3¼ in. long, and connecting-rod bearings are 2⅛ by 2 1.8 in. The forked-rod system is employed.

Inclined Valves Reduce Combustion Space

A single camshaft is used, it having sixteen cams, one for each valve, and to bring the ends of the tappets in direct contact with the cams, the valves are inclined at a greater angle than the cylinders, thus bringing them to the camshaft at their lower ends and swinging them in closer to the combustion chambers at the top.

The camshaft is driven by gears from the crankshaft, but outside of the camshaft gear, and on the same shaft, is a sprocket over which a silent chain runs to a sprocket on the generator, fan and distributer shaft directly above. The gears and chains are neatly inclosed by a stamping at the front and a compact appearance is the result.

One notable feature is the location of the ignition distributer, mounted on top of the support of the fan end of the upper shaft. The distributer is an entirely separate unit from the generator, and it is driven by spiral-gear connection with the fan and generator shaft. The position places it conveniently, from the standpoint of assembly and also of accessibility for adjustment.

The fan, by a nice bit of designing, is arranged for practi-

cally positive drive without noise and at a moderately high speed. Its drive is through a friction clutch, the tension in a coil spring on the end of the shaft serving to make the driving connection while the center portion of the fan acts as a housing for the spring as well as the friction part of the little clutch. The tension in this clutch is such that while the fan can be turned by hand when the motor is not running, still there is no slip when the motor is operative. This makes a flexible drive similar in action to a belt, though a more mechanical job.

Electrical System Has Three Units

Through the use of the Delco three-unit electrical system, it has been possible to dispose the electric apparatus without undue congestion of the V between the cylinder blocks, or the fitting of any unit into too small a space. By locating the generator at the rear end of the shaft that drives the distributer and fan, it has an accessible and logical position with provision for efficient drive. The starting motor is placed on the right side of the gearcase within easy reach through the front floor boards and gears to the flywheel through the Bendix drive with the shift forward. By this placing of the electrical apparatus, there is nothing in the valve-alley except the carbureter and the manifolds, besides the generator at the front end.

A good position is given the water pump which is of a double outlet type. It is mounted on the front end of the camshaft, outside the housing of the gears and chain, and this makes for the minimum of water piping, and at the same time gives a very simple direct drive for the cooling unit. A water connection runs from either side of it around the gear housing and chain to the front end of the adjacent cylinder block, while from the right side there runs the pipe connection to the radiator. This symmetrical arrangement of the pump with piping equidistant from either block of cylinders should make for very uniform cooling.

The force-feed engine lubrication uses a gear pump at the front of the motor under the timing gear cover plate. This pump oils the two main bearings under a moderately high pressure which reaches a maximum of 30 lb. to 40 lb. per square inch at maximum crankshaft speed. A check valve regulating the pressure, opens when the prescribed maximum is reached, the surplus then by-passing to the camshaft bearings and the front gears and chain. Through the drilled crankshaft the connecting-rod lower bearings are oiled and the overflow from these is sprayed up into the cylinders and the other bearing surfaces. There is an adjustment provided for regulating the tension of the spring of the check valve, this governing the pressure of the oil. The system is practically the same in principle as is working successfully on several other eights.

The Stewart vacuum fuel feed has the tank placed in the center of the back of the dash in the rear end of the engine V, which brings it close to the carbureter, making the fuel pipe very short. The gasoline tank is suspended at the rear of the chassis, as on the four-cylinder car.

Wherever possible, for the sake of standardization, the chassis of the new eight is the same as the four, but there are parts which must necessarily be heavier. There is really very little difference in the total weight of the two models, so parts that have only a weight-sustaining function did not need enlarging, whereas those taking the drive are necessarily stronger. For instance: while the two cars have the same frame and front axle, the eight possesses a heavier rear axle; the housing is a larger and heavier stamping and the driving shafts are increased, although of exactly the same general design. The gears are of nickel steel and are the spiral-bevel type to promote silence. The ratio is 4 5/12 to 1, so that the engine really has plenty of chance to handle the car well. Ball bearings are employed in the axle.

Hotchkiss Drive with Underhung Springs

Transmission of the power from the motor is through a cone clutch and three-speed gearset in unit with the engine, and a tubular drive shaft of open type, fitted with two universals. The clutch form offers nothing radical, having engagement springs which admit of ready adjustment. It has a diameter of 12½ in. Compactness is notable in the gearset which is fitted with hardened steel gears with the transmission shaft mounted on ball and roller bearings.

In using the tubular drive shaft, the car has a stronger driving member than if it were solid, and whipping is reduced to the minimum. As in this year's four, the eight uses the Hotchkiss type of drive with the propulsion and torque taken through the rear springs, the master leaf of each being made to care for these added duties. This form of drive makes for lightness.

Rear springs are underhung, and like the fronts are mounted so as to be nearly flat under normal load, the idea being to promote easy riding along with good treatment of the springs. When normally flat, it is obvious that the spring action will be above and below the horizontal, making for uniformity of bending in either direction.

Every Inch an Olds

One could immediately tell the new eight as an Oldsmobile if familiar with the appearance of previous Olds' cars. The body and cowl are characteristic, although radiator and hood are more rounded than heretofore. The paneled doors, cast-aluminum running boards, Circassian walnut dash and steering wheel are all features possessed by the new model as well as the four. To afford some idea of the roominess of the body, a few of the dimensions will suffice: Doors are quite wide—23 in., and admit to a rear seat of 46-in. width; the distance from the back of the rear seat to back of front is 48 in.; the length from the back of the front seat to the clutch pedal is 41 in., and the clutch and brake pedals are adjustable.

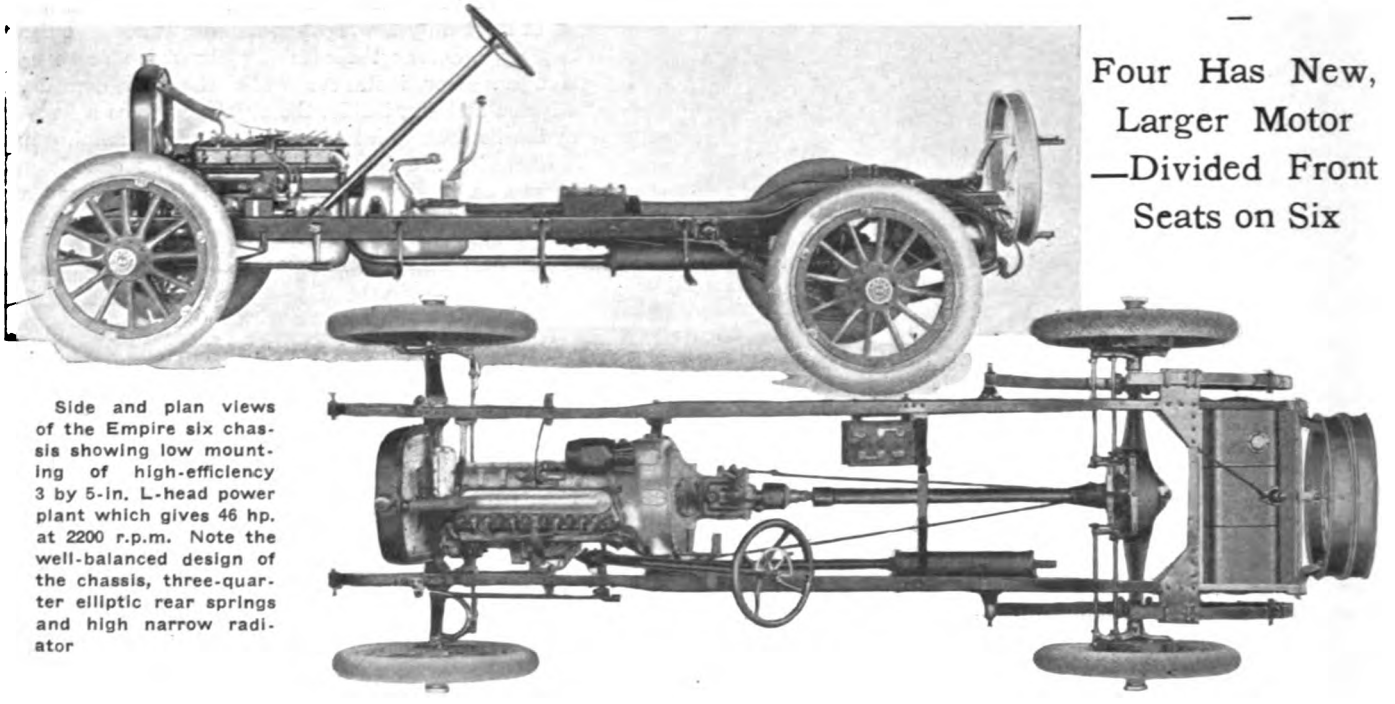
Empire Six in Production

Four Has New, Larger Motor —Divided Front Seats on Six



Side and plan views of the Empire six chassis showing low mounting of high-efficiency 3 by 5-in. L-head power plant which gives 46 hp. at 2200 r.p.m. Note the well-balanced design of the chassis, three-quarter elliptic rear springs and high narrow radiator

IN the production of a six-cylinder touring car at $1,095, the Empire Automobile Co., Indianapolis, Ind., takes its first departure from the building of a four-cylinder car, all previous models having been of the latter type. The former four has been discontinued and a new model takes its place. Last year's four listed at $975, while its successor will sell for $895. As to wheelbase, frame, drive, axles and equipment the new four, which is a five-passenger, closely resembles its predecessor, but the power plant and body have come in for some changes.

Of the two models the six is the more attractive in point of appearance, giving the idea of massiveness with its long wheelbase of 120 in., its body with extreme roominess and a long, high hood. The body is of the curved cowl, convex-side design. There is a noticeable departure from this concern's seating arrangement in its four, the six having individual, parlor-car seats in front. The rear seat is 49 in. wide and accommodates three passengers. In the chassis of the six there is a close adherence to the previous Empire design, although it is longer and heavier than previous models put out by this company. Springs are attached the same as on the previous four, with bridge construction gusset plate at the rear, but an innovation is that the rear springs are underslung.

Another feature that has been adopted for the first time in Empire cars is the vacuum gravity fuel feed. Tires are larger than heretofore, 34 by 4 being standard equipment for the new six, with non-skid rear. The rear axle is new, being of the floating type with pressed steel housing and removable inspection cap.

Six Is High-Speed Motor

The power plant of the six is of the high-efficiency type with cylinders measuring 3 by 5 in., giving 46 hp. at 2200 r.p.m. The cylinders are of the L-head type with valves overhead measuring 1⅝ in. and having a 5/16 in. lift. A three-bearing crankshaft is used, the main bearings being split into upper and lower halves. All bearings are babbitt-lined with bronze shell. Connecting rods are 9 in. in length and the lower bearing has a diameter of 1¾ in. and a length of 2 in. Splash and plunger pump lubrication is incorporated in the Empire power plant. The camshaft is submerged in an oil reservoir, which is designed to give greater silence. Cooling is by a centrifugal pump and a Fedders high, racing-type cellular radiator.

Connecticut ignition and Schebler carbureter are standard equipment on the new six. Current is provided by an Auto-lite generator placed on the left side of the motor and is stored in an oversize, six-volt Willard storage battery. The motor is started by the Auto-lite equipment, operated on the flywheel through a Bendix drive, which marks the first time the Empire has used this type of starter on its cars.

Heavy Shafts Feature Gearset

In the power transmission all gears and nickel steel shafts are made extra heavy, while the main driving shaft is mounted on New Departure ball bearings. The universal is the Hartford, heavy car type, inclosed in a pressed steel housing to make it oil-tight and dust-proof.

The rear axle is a Weston-Mott, single-bearing, full-floating, with large housing and a 12-in. inspection cap. This has been designed to relieve the shaft of carrying weight, the housing taking care of the weight. Hyatt roller bearings are found in the axles, except behind the driving pinions where double rows of New Departure bearings are used. The front axle is dropped to give a lower center of gravity, but the standard 11-in. clearance is maintained.

Left drive with center control is found in the new six. Two sets of brakes are used, both on the rear wheel drum and the equalizer system is particularly well laid out. The hand-brake lever is connected to the equalizer by a steel cable.

Fenders are of the crown type, pressed steel, with close fitting shields. All fender edges are reinforced and the baked enamel process gives them a lasting luster. The running-boards are linoleum covered and aluminum bound. The body is among the cruiser types of the 1916 season, made in alumi-

noid steel with convex sides and rolled cowl. Semi-elliptic, 36-in. springs are found in front and three-quarter elliptic, 53-in., in the rear, while the upper main leaf of each rear spring is scrolled to do duty as a bumper plate. The frame is dropped, to lower the center of gravity, and narrowed in front to shorten the turning radius.

New T-Head Engine on Four

In the new four-cylinder model Empire the motor used in the previous model has been replaced by a Teetor, T-head power plant, 3⅞ by 5 in., which is considerably larger than the previous plant used, which was 3¾ by 4½ in. In this model the disk clutch has been discarded in favor of a cone. The gearset is a regular three-speed, made by the Detroit Gear and Machine Co. The new four uses Connecticut ignition system in place of the Remy found on last year's four, while the starting and lighting is by Auto-lite, two-unit, like the six. The steering post is a new one also, made by the Foster Gear Co., Columbus, Ohio. Tires are 33 by 4, instead of 32 by 3½.

The foregoing paragraph tells the principal changes to be found in the new four. Going back to the motor, the crankcase incorporates features of the barrel-type construction, giving rigidity to the bearings, of which there are three. The T-head construction allows unusually large valves with a 2-in. clear diameter. All valves are interchangeable and have cast-iron heads, electrically welded to nickel steel stems. The intake manifold passes through the cylinder block, which completely jackets it with hot water.

The lubrication system consists of two overflow oil basins located in the lower part of the crankcase. In the bottom of these basins holes are bored to admit a given quantity of oil. The lower ends of the connecting-rods pass through this oil, keeping a certain amount in circulation and directing excess oil to the reservoir; directly over each main bearing is an oil pocket, cast integral with the crankcase.

Cooling is by thermo-syphon in connection with a Fedders cellular-type radiator. Wheelbase is 112 in. and the body is of the conventional streamline design. Exceptional leg room is given by the wide, low-set seats. Upholstery is of leather throughout. The gravity system of fuel feed is employed in the four, from a 14-gal. tank under the front seat. Semi-elliptic springs in front and three-quarter elliptic in the rear are used, the latter being also underhung.

Equipment for both the four and six is practically the same, and includes combination head lamps with powerful searchlights for country driving, tail and tonneau lights, one-man top with curtains operated from inside the car, rain vision, ventilating windshield, Stewart speedometer, Stanweld demountable rims with one extra, dash carbureter adjustment, twin spare tire carrier, rubber shock absorbers for front and rear springs, robe and foot rails, motor-driven horn on the six and an electric horn on the four, extension inspection lamp, tool kit, jack, etc. The six is finished in Brewster green, or royal blue body, with black running gear, striped with white, and vermillion wheels, the four in Brewster green or French grey, with black running gear and wheels.

Cotton Advance Booms Sales In South

ATLANTA, GA., Oct. 16—The rapid advance in cotton prices has boomed the sales of automobiles in the South. Dealers in this city are at present getting more orders than they can fill. At present there is a large shortage of cars here. Some of the agents are offering bonuses to agents in other sections if they will divide the machines allotted to them.

Business conditions throughout the South are picking up with a consequent demand for cars. Several of the automobile manufacturers are taking advantage of the recent boom and are establishing headquarters in this city.

Automobile agencies in this city report large increases in business over that of 1914. The Buick agency shows an increase of 350 per cent. Reports from the various Buick agencies throughout the South state that they are nearly 1000 cars short on their orders.

Some of the Southern people are preparing to buy pleasure cars who had never thought of such a thing before. Instances are known where people have saved exactly enough money to buy an automobile.

The agency for the Maxwell, Mitchell and National has more orders than it can hope to fill on time. The manager of the concern states that the southern companies are going to have the best automobile year ever known in the history of the South. It is claimed that the action taken by the banks all over the country to remedy the depression of several months ago has had a wonderful effect.

The Cadillac agency is thirty cars behind in orders. Many sales are being made to farmers.

The Haynes company has established headquarters in this city at 239 Peachtree Street as a result of better business conditions.

Maine Spends $6,516,000 for Cars

PORTLAND, ME., Oct. 16—Maine people have spent $6,516,000 for automobiles during the past year, according to Secretary of State J. E. Bunker's estimate. This estimate includes 360 trucks, costing $226,000. Automobile taxes have yielded to the State treasury $258,665, and 24,326 operator licenses have been granted. The receipts for the entire year of 1914 were only $192,000, or $66,665 less than for 1915.

The Rostrum

Loose Connecting-Rod Causes Knock

EDITOR THE AUTOMOBILE:—I have an elusive knock in my Buick six model D-45 which seems to baffle local experts and, as usual, I turn to THE AUTOMOBILE for assistance. The knock has always been present in this car, which has been run 1200 miles, but seems to increase the farther I run it. This noise is not heard at speeds under 25 m.p.h., and is of a metallic nature. Have been over the tappets several times and am satisfied the trouble is not in them. Have not investigated the bearings, but it seems hardly possible to have a loose bearing in a brand new car, although the knock is of that nature.

The noise is not heard with the spark retarded, being present only when fully advanced. I have been told that it is a spark pound and that I must run with a later spark, but this results in reduced efficiency and heating up of the engine, besides being contrary to the instruction book which says to run with spark lever fully advanced on the sector. I have also been told that this noise is characteristic of this car, being caused by the automatic spark advance mechanism, but I fail to see why this centrifugal governor should cause a knock.

I might add in conclusion that there is no difference in the intensity of the knock whether running on the level or ascending a grade, it being present at all speeds above 25 m.p.h. regardless of the position of the throttle.

This knock is very annoying and has resulted in much ridicule being cast upon the car and the driver, and anyone who can locate the trouble and suggest a remedy will earn my everlasting gratitude. D. C. C.

East Canaan, Conn.

—From your description of the symptoms, it seems quite certain that this knock is due to a loose connecting-rod. This can be corrected by removing the lower half of the crankcase, loosening the connecting-rod cap and removing one of the thin metal shims on one side.

New Coil Would Improve Ignition

Editor THE AUTOMOBILE:—I have a 1913 Ford car which jerks a little whenever I run it at the rate of 9 or 10 m.p.h. I was told that such a jerk came from the differential gears because they have too much play. I really do not believe this could be the cause, as the motor pulls well. I do not think the differential should have any effect on the car even if it has much play. I installed a master vibrator because I thought the coils were too weak and once in a while the motor would miss fire. The man who told me about the differential said that there is no use in using the master vibrator, because if the coils are too weak, I should replace them with a new set. Would like your opinion on this. J. T.

Houston, Tex.

—Misfiring of the Ford motor at low engine speeds may be the result of a number of conditions. The most probable causes of the trouble are: Poor compression on account of leaky valves; improperly adjusted carbureter, causing too rich or too lean a mixture; dirty spark plugs; coil vibrators improperly adjusted or points dirty or burned; air leak in intake manifold; weak exhaust valve springs; too great clearance between valve stems and push rods; too small gaps between spark plug points; or, possibly imperfect contact in the commutator.

It is certain that the condition of the rear axle assembly has no effect upon the irregularity of the motor. There is a Ford service station in Houston at which any repairs can be made. The Ford company does not approve of the use of master vibrators, though various ignition companies recommend them. It is certain, however, that if your coils are weak the replacement of your present coil with a new Ford coil would improve your ignition.

Missing Due to Sticking Valves

Editor THE AUTOMOBILE:—The two front cylinders in my car will run for days and weeks without causing any trouble and then, without apparent cause, will cease firing, the cylinders flood with gasoline and the motor will heat up. On these occasions, the plugs give good fat sparks every revolution—I have tried them with a screwdriver—but there is no explosion in the cylinders. What do you think is the trouble, its cause and its remedy? N. R. F.

Mauch Chunk, Pa.

—The trouble with your two front cylinders seems to be sticking valves. The fact that you state that the motor overheats at the same time would lead to the belief that this is a cause and not an effect. The probabilities are that the motor starts to become overheated, causing the valves to stick, which in turn gives rise to misfire. You should look carefully to see that the valve stems have proper clearance, that they are not bent and that the cooling system is clean and in good order. The latter can be aided by flushing out with a saturated solution of common soda.

To Time Four and Magneto

Editor THE AUTOMOBILE:—Kindly let me know the quickest way to time a four-cylinder motor and also the magneto.

Red Bank, N. J. J. P.

—The quickest way to time a four-cylinder motor is to take advantage of the markings on the flywheel. You will note that the point of intake opening and exhaust opening for each cylinder is marked on the flywheel, the mark, for instance, of intake opening No. 1 cylinder being 1.0. No. 1 indicating intake opens for No. 1 cylinder when this mark registers with the mark attached to the engine frame. The camshaft gear and the magneto gear should be taken out of mesh and the flywheel brought around so that this mark registers with the mark on the engine frame or indicator as is sometimes used. The camshaft should then be turned, and when it is in such a position that the function indicated by the flywheel mark is taking place, the camshaft gear should then be slipped into mesh.

In timing the magneto the mark on the flywheel is carried around to upper dead center at which position the spark for that cylinder should be taking place with the magneto set at full retard. The timing of the magneto itself will depend upon the make and model. The armature shaft of the magneto is always arranged so that a spark of maximum intensity is provided at the moment of breaking the circuit in the breaker box. The means for attaining this end varies with

the different makes of magnetos and should be learned from the manufacturer's instructions or will be furnished through the Rostrum if you will give the name and model of the magneto.

Glycerine for Anti-Freeze Solution

Editor THE AUTOMOBILE:—Will you kindly tell me of some practical way to filter cylinder oil to remove the carbon after it has been used in the engine?

2—Are there different grades of glycerine and what grade is best to use in the radiator to form an anti-freezing solution?

Winchester, N. H. H. B. H.

—THE AUTOMOBILE has no record of any practical way to filter cylinder oil to remove the impurities after it has been used in the motor. Some people use this old oil for gears and state that it has proved quite satisfactory.

2—There are several grades of glycerine, depending upon the purity. The C. P. or chemically pure grade should be used in the radiator.

Maximum R.P.M. of Long Stroke

Editor THE AUTOMOBILE:—Is a long-stroke motor capable of turning over faster than a short-stroke?

2—Would a 4½ by 6-in. six-cylinder motor turn faster than a 4½ by 5½ motor of the same design?

3—How fast will the highest speed motor turn? What are the dimensions of one of these?

Beaver Falls, Pa. E. S.

—No, not so fast, limiting speed is piston speed in feet per minute, not revolutions per minute.

2—No, not quite so fast, if of equivalent engineering standard of design.

3—The highest speed motors in commercial use will turn at about 3000 r.p.m. The dimensions would be about 3 in. by 5 in.

Installing Ammeter on 1912 Buick

Editor THE AUTOMOBILE:—Will you please give me instructions through the Rostrum department of THE AUTOMOBILE regarding the proper way of installing an ammeter on a Buick car B-25, 1914 model?

Williamsport, Ohio. C. E. H.

—In order to properly install an ammeter on a B-25, 1914 Buick car it will be necessary to remove the motor generator from the car and take it apart. When the motor generator is taken apart it will be noted that there is a brass strip connecting the larger and smaller terminals on the side of the motor generator frame. This strip of brass must be removed and the motor generator reassembled. Then by attaching one terminal of the ammeter to the larger terminal on the side of the generator frame, and the other terminal of the ammeter to the smaller terminal on the side of the generator frame, the ammeter will be correctly connected except as to its polarity. This can readily be determined and the leads to the ammeter reversed if necessary.

The Delco company recommends that where installations are made, that an ammeter having a zero center and a range of 30 charge and 30 discharge be used. The installation is shown in Fig. 2 as regards the strap connection between the terminals and a wiring diagram is also given in Fig. 1.

Rebuilding 1909 Cadillac for Speed

Editor THE AUTOMOBILE:—I have an 1909 model Cadillac which I am going to convert into a two-passenger raceabout and I would like to have you answer the following questions through the Rostrum columns of THE AUTOMOBILE.

1—Is there any method by which the steering column can be lowered?

2—It has a Bosch magneto and would like to know how often it should be overhauled, and what should be done?

3—Kindly show by drawings, etc., a body with bucket seats, gasoline tank in rear seats, tire carrier, tool box, etc., under rear deck.

4—Offer any suggestions that would tend to increase the speed and what should the speed be with a gear ratio of 3.5 to 1 and 33 by 4 tires? A. T.

Wenatchee, Wash.

—There is no method of lowering the steering column used on the 1909 Cadillac. It is possible, however, that the steering gear used in the 1909 roadster could be placed in this car, and as the roadster steering gear makes a smaller angle with the horizontal than the touring car steering gear, the desired result might be obtained in this manner. This, however, would be considerable work, as it would be necessary to secure an entirely new roadster steering gear as well as making it necessary to secure parts in order to fit the steering post to the front of the car at the point where it passes through the dash. Special brackets are necessary for this purpose, and besides this considerable fitting would probably be necessary.

2—There is no rule by which you can go in the number of times a Bosch magneto has to be overhauled. THE AUTOMOBILE has record of a certain Franklin car which has traveled 150,000 miles without having the magneto touched other than occasionally cleaned. There are a great number of cars

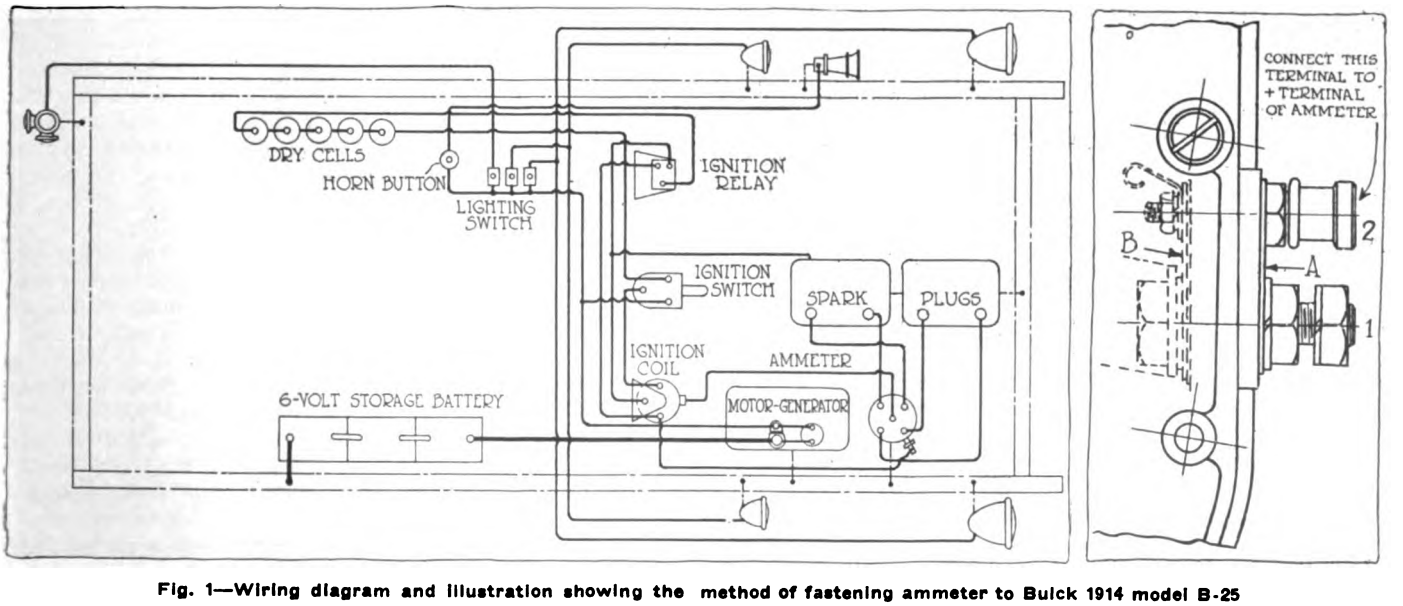

Fig. 1—Wiring diagram and illustration showing the method of fastening ammeter to Buick 1914 model B-25

which have gone five or six seasons without even having the magnets charged.

3—By referring to your file of back copies of THE AUTOMOBILE, you will find a large number of bodies which coincide with the outline you give.

4—As to what speed this car should make with 3.5 to 1 ratio, and 33 to 4 tires, this of course would depend upon the possible r.p.m. of the engine. This is a matter which is rather indefinite and difficult to ascertain on a car of this model. The standard 1909 gear ratio for the touring car was 3½ to 1, and for the roadster 3 to 1. If one is looking entirely for speed, the higher gear ratio should of course be used. The standard tire on this car is 32 by 3½, the effect of putting on 33 by 4 tires is the same as would be obtained by putting on a higher gear ratio; that is, while the ultimate speed is higher, the acceleration is decreased.

Calculating Horsepower of Gears

Editor THE AUTOMOBILE:—Would you kindly supply me with a formula for calculating the horsepower of cast iron and steel gears?

Brooklyn, N. Y. L. H.

—The method for calculating the horsepower which can be safely transmitted by cast iron and steel gears is the same. The following formulae are based upon cast iron and for steel it is only necessary to multiply the result by 2.5:

F = Breadth, or face of tooth in inches.
T = Thickness of tooth at pitch line, inches.
V = Velocity at pitch line in feet per minute.
L = Length of tooth, from root to point, in inches.
C = Co-efficient.
Hp. = Horsepower transmitted with a factor of safety of eight; ultimate tensile strength 30,000 lb. per square inch.

FORMULAE

(1) Horsepower of Spur Gears = $\frac{F \times T2 \times V}{L \times 53}$

(2) Horsepower of Bevel Gears = $\frac{F \times T2 \times V}{L \times 77}$

(3) Horsepower of Miter Gears = $\frac{F \times T2 \times V}{L \times 82}$

(In formulae for bevel and miter gears, the factors T and L express the pitch at large end of tooth.)

For bevel and miters, thickness and length of teeth have been computed at center of face. With a view, however, of facilitating calculation, the proportions of factors T and L in formulae (2) and (3) have been taken at large end of tooth, thus giving same dimensions as for spur gears; hence the spur gear formula has been utilized, with the exception of co-efficient, which has been determined by averaging the proportions of teeth of bevel and miter gears having the largest and smallest number of teeth in general use. The resultant horsepower is consequently less than in the case of spur gears of like pitch.

For mortise wheels and pinions use thickness of pinion tooth. If different margin of safety is desired, multiply above result by 8 and divide by factor of safety desired; 2200 ft. per minute at pitch line for iron gearing and 3000 ft. for wood and iron, are excessive velocities, and should be avoided if possible.

Farm Tractor Field Widens

13,000 in Operation in States West of the Mississippi— 7,000 Is Estimate for East

FARM power, exceeding in extent and cost that for any other purpose, even manufacturing in all branches, is to-day the only great field of power consumption which depends upon animal power in the main. Phillip S. Rose, editor *The American Thresherman* and the *Gas Review*, Madison, Wis., in an address delivered before the International Engineering Congress at San Francisco last September, made the prediction that this giant among power-consuming industries would also adopt mechanical power for the greater part, and that soon.

Mr. Rose points out that the preferred use of horse and mule power by American farmers, in spite of its greater cost per unit of energy, is due to the greater "activity" or versatility of the animal as against the engine. He further states that the 24,042,882 horses on farms in 1910, have grown to 25,411,000 up to Jan. 1, 1915, by estimates of the Department of Agriculture, of which 20,328,800 are mature work animals. Each horse develops 7/10 hp. so that the animal power on farms is estimated by Mr. Rose to aggregate 14,230,000 hp. The value of these horses is $2,842,655,000 and their harness, $203,200,000, a total of $3,045,855,000, or $214.05 per horsepower. He quotes Professor Gebhart of Armour Institute, Chicago, to show that steam power plants cost $200 to $175, the cost varying inversely as the power of the plant.

The number of farm horses has increased from about 7,000,000 in 1870 to about 21,000,000 in 1914, and the acreage worked has increased from 185,000,000 in 1870 to 500,000,000 in 1914, so that though the increase in power available and work to be done has kept approximate step, the actual acreage worked per horse has decreased from 20.3 in 1870 to about 19.2 since 1900. This greater power expended per acre is explained by two things; namely, deeper plowing and scarcity and rising cost of farm labor. The draft on a plow in ordinary soil increases about in proportion with the depth of the furrow in inches, so that deeper plowing, which all authorities indorse, requires more power. The scarcity and dearness of farm labor has given rise to heavier machines, such as gang plows, combined harrows and grain drills, larger harvesters, etc., so that each unit of labor is able to compass a greater amount of work per day or so that each farm requires a smaller number of hands.

This has led to the breeding of heavier and heavier draft animals for the farm until the limit has about been reached. Further development along the above lines requires that the horse with his limitations be discarded and the limitless power of the internal combustion engine employed in his stead. Concerning this, Mr. Rose says:

Mechanical Farm Power

"Available mechanical farm power consists of steam engines, internal combustion engines, wind mills and water power. Electric power, generated either by steam plants or hydro-electric stations, is used to a limited extent in some favored localities, as along the Pacific seaboard, in Montana and in some of the Central States, but, as yet, it has not come into serious competition with any of the other powers.

"Small water-power plants are available in only a few favored localities, and then the cost of the dam and power equipment is exceedingly high, so this kind of power may be left out of general consideration.

"The use of windmills has been on the decline for a number of years. The principal objection to their use is the

smallness of the power units and the uncertainty of obtaining power when needed.

"This, then, leaves only two sources of power for serious consideration, namely the steam, gas or oil engine. The former has been in use in this country since about the year 1830. Steam did not come into very extensive use until after the Civil War, and then only for operating threshing machines, running small saw-mills and for grinding feed. Experiments were made in this country, along in the seventies and eighties of the last century, with steam plowing outfits but not with much success, either because the engines were not designed rigidly enough, or because the country was too poor to invest in such costly machines. Probably both causes had an influence on the situation.

"About the year 1898, however, when the Western prairies were being opened up so rapidly, a demand arose for heavy power outfits to break up the virgin sod and within the next five years a number of excellent steam rigs were put on the market. Practically every threshing outfit sold throughout the West in the early nineties was sold not only for threshing but for plowing also. Thousands of acres were broken by these rigs, but their great weight and the difficulty of getting water to them on the dry Western plains created a demand for something different and better.

The Gas Tractor Appears

"It was these conditions, together with the rising price of horses, that paved the way for the gas tractor. The first of these machines came out about the year 1900, but it was not until six years later that they became practical machines. Two companies divide the honor of being the pioneers in this new industry, the Hart-Parr Co. of Charles City, Iowa and the Kinnard-Haines Co., Minneapolis, Minn. The success of these machines brought into the field a host of competitors among the old threshing machine manufacturers, and by 1912 the tractor industry had grown to considerable proportions. That was the banner year. It was freely predicted by many enthusiasts that the horse was doomed and that in a very short time all farm work would be done with tractors. They practically crowded the steam plowing outfits off the market and thousands of farmers bought them.

"A considerable number succeeded with the tractor, but a larger number failed. In some cases, the cause of failure was due to the failure of the machine, but in the majority of cases it was due either to the ignorance of the operator or to the fact that his style of farming was not adapted to power machinery. It was also found that the heavy outfits that were used to break up the prairies were not adapted to general field work, and so the industry has suffered a partial collapse during the last two years. Another factor that contributed to the general slump in business was the faulty methods employed by most of the companies in doing business. The market was not well sold. Farmers were induced to buy, who could not possibly make a success with a tractor, and there was not enough care given to the instruction of the operators. The tractor has suffered in comparison with the automobile because the latter has had the help of countless garages to help keep them in good working order. The tractor, on the other hand, has had to get along generally without any expert attention. Invariably, those who have made a success have been good mechanics. In fact, failures among mechanics or those of fair mechanical ability have been rare.

Demand for Light Type

"At the present time there is a decided revival in the use of the light-weight tractor that sells for a few hundred dollars and will take the place of a half dozen horses. There are perhaps fifty companies that will bring out a light-weight tractor this spring in response to a demand by the farmers of the corn belt and wheat belts. This demand is not one that has been worked up by ingenious and persistent advertising but comes from the farmers themselves, who realize the limitations of animal power and who desire to do a better grade of farming than they have done in the past. Just how the light-weight tractor will develop is difficult to forecast at this time, but where such a genuine need exists there seems little doubt that the manufacturers who have had a number of years' experience will be able to produce a machine that will be able to supplement the horse and the mule, even if it does not displace them. The present tendency toward very light machines, weighing only 3000 or 4000 lb., probably marks the extreme swing of the pendulum toward light weight. The tractor that appears, to the writer, to have the best chance for ultimate success will weigh from 6000 to 8000 lb., and have about a 30-hp motor.

"A careful canvass of the States west of the Mississippi made last winter by A. P. Yerkes, a government agent connected with the Bureau of Farm Management of the United States Department of Agriculture, shows that there are something like 13,000 tractors in operation. There are probably not to exceed one-quarter as many east of the river, making something less than 20,000 tractors in use in the entire country. These tractors vary greatly in size, but will doubtless average close to 40 brake horsepower each.

"The possibilities for the use of tractors are, however, almost unlimited when the number of farms of large size containing 175 acres or more, is considered. Each one of these farms would appear to be large enough to make profitable use of some form of mechanical power for general farm use, provided one can be built and sold for a price at which the farmer can afford to make the investment.

"Steam traction engines are still used as the principal source of power for threshing, and it does not seem likely that they will be displaced entirely for a great many years. From the best information available, which, by the way, the writer has checked over in several ways, it is estimated that there are a total of close to 100,000 steam tractors in this country used for threshing and other agricultural work. The average brake horsepower of these machines is probably about 40. Quite a large number are used for plowing, for filling silos, grading roads, grinding feed, shredding and husking corn and for operating small portable saw-mills.

Automobiles Fill a Mission

"There is still left the automobile and the farm truck to consider. The latter is used very little, but of the former the number is very large, running into hundreds of thousands. In the State of Iowa alone it is estimated that there are 65,000 automobiles owned by farmers, and a number of other States are not much behind. Since these are primarily passenger machines rather than farm power machines, I shall not spend much time with their consideration. Suffice it merely to say that they are finding a rapidly increasing use in marketing light farm produce and paving the way for better roads and for the use of trucks.

"I said in the beginning that farm power exceeds in value and amount that is used in all manufacturing industries. The proof has been submitted, but to make it more apparent let us tabulate the results:

Kind of Power	Number	Average Value	Total Value	Total Power
Horses and mules	25,411,000	$111.85	$2,842,655,000	14,230,000
Harnesses	20,382,000	10.00	203,820,000	.....
Windmills	750,000	100.00	75,000,000	75,000
Steam tractors	100,000	.....	.....	4,000,000
Gas tractors	20,000	2,000.00	40,000,000	600,000
Gas engines	1,000,000	150.00	150,000,000	5,000,000
			$3,311,475,000	23,905,000

"The total power used in all manufacturing enterprises, according to the 1910 census, was 18,755,286 hp. Even allowing a large margin for possible error, it is thus seen that the farmer's power problem is a big one and involves millions of dollars. Mechanical power, as yet, is much smaller in amount than animal power, but it is rapidly increasing and within a few years will doubtless assume first place."

ACCESSORIES

New-Speed Carbureter

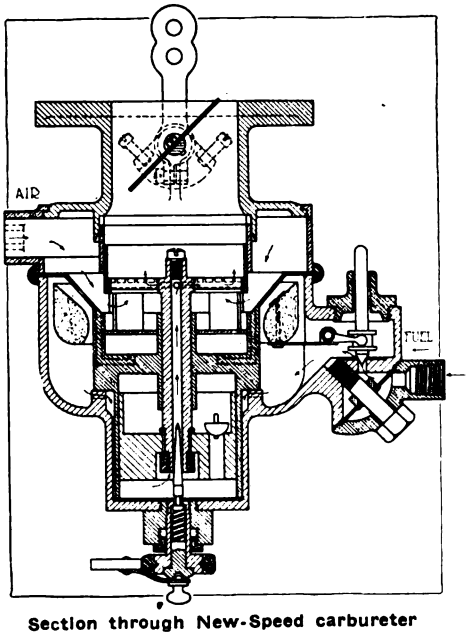
ALTHOUGH named the New-Speed carbureter this instrument is intended for all speeds, but takes its appellation from James Speed, its inventor. This is an automatic design and, as will be seen from the section, is controlled by a floating air valve which is raised by the suction of the motor. This valve, which the makers have called the elevator, is located in the neck of the carbureter and has ports cut in the sides, which correspond with ports in the passage in which the elevator travels.

Under normal conditions when the motor is idling the elevator is in its lowest position which closes all ports and only allows fuel to enter through a simple passage. Cross-wise in the top of the elevator is placed a row of jets which are designed to take care of the diffusion of the fuel.

There is also a piston placed in a separate compartment in the center of the float chamber directly beneath the fuel elevator, and attached thereto by a fuel stem. The piston being attached to the fuel elevator travels at the same distance as the latter and is of sufficient weight to insure proper balance and proper closing of the fuel elevator. It is through this fuel stem that the gasoline travels to the row of jets in the top of the elevator.

The amount of fuel flow is governed by a metering pin mounted vertically upward beneath the fuel stem. As the elevator rises, carrying with it the stem, the taper in the pin governs the amount of fuel admitted. The greater the suction the higher the floating valve lift, and therefore, the greater the amount of fuel and air. Since the meters are all straight tapers, it is only necessary to put the right taper pin for a given motor and to adjust it properly for idling. After this it will be automatically correct for every other speed.

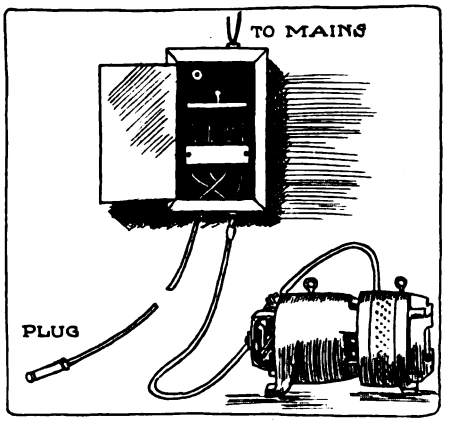
The combination dirt and water strainer is placed in the gasoline intake adjustment. There is no float adjustment as this is correctly placed at the factory. Prices vary from $20 for the ¾-in. size to $45 for the 2-in.—New-Speed Carbureter Co., San Francisco, Cal.



Section through New-Speed carbureter

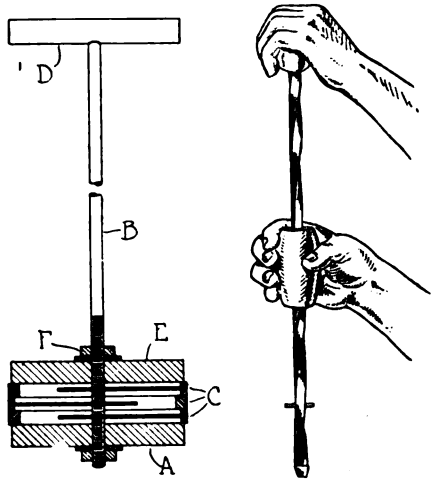
Milburn Light Electric Charger

A charging apparatus which any owner can use to charge the battery of his electric passenger car is now out under the name of the Milburn Light Electric Charger. It is designed especially to meet the needs of persons who desire to take care of their own batteries. With it the electric car owner need only turn the main switch in the car to charge position, insert the charging plug in its receptacle and close the switch in the wall panel provided with the apparatus.



Milburn light electric charger showing connections

The machine consists of a compound-wound-direct-current generator direct connected to a standard single-phase squirrel cage induction motor. The squirrel cage motor is non-self-starting and the outfit depends upon starting from the direct-current end. This is accomplished by a four-pole switch, the two middle prongs of which stick up higher than the others. After the switch is thrown in slowly, the shunt field is excited and then the armature of the direct current is thrown directly across the battery. The set then begins to revolve, the generator acting as a shunt motor, the series field being cut out by means of the clip. As the switch is thrown into the last step the alternating current is thrown onto the motor and the outfit starts to charge the battery. Being compound-wound, the outfit approaches a constant potential method of charging, the charge starting at a high rate and slowly tapering to a low finishing rate. This gives a charge which is non-gassing and will very materially increase the life of the battery. The outfit is made two-bearing, ball bearing so that all difficulties from bearing trouble are eliminated. The price varies from 110 or 220 volts, 60 cycle, $130, to 25 cycle, $140.—Lincoln Electric Co., Cleveland, Ohio.



Left—Peerless piston ring lapping tool for fitting new rings to worn or oval cylinders. Right—Michener valve grinding tool

Stevens Countersinks

This set of countersinks for fitting brake and clutch linings consists of 9/16, ½ and 13/32 in. countersinks for Nos. 7 to 11, inclusive, flat head rivets having countersunk heads as well as for all sizes of similar rivets. As the shank of the countersinks is 5/16 in. in diameter, they can be used in a hand drill or power press. These tools are said to cut a clean and accurate hole very rapidly. The set sells for $1, but single sizes can be obtained.

For garage and repair shop stocking the Stevens company is producing boxed assortments of iron and brass wood screws, machine screws with nuts, iron bolts and copper rivets with burrs. No. 10 assortment consists of the above named packed in a strong cardboard box. —Stevens & Co., New York City.

Peerless Lapping Tool

For fitting new piston rings to worn or oval cylinders the Peerless piston ring lapping tool has been brought out, to avoid running the car 100 to 1000 miles in order to lap in the rings with inferior results. The lapping tool comprises a handle, connecting-rod and disks

and nuts for holding the piston rings in position while lapping.

To lap in the piston rings, referring to the illustration, place the lower disk *A* with rod *B* in the cylinder. The rings *C* are slipped over the handle *D* on to the disk in the same position in the cylinder as they are to be used in the piston. The pins are then inserted and the upper slotted disk *E* is placed in position and held firmly by the clamping nut *F* which is lightly turned into position. The cylinder is then charged with piston ring lapping compound and about twenty-five strokes are made with the handle *D* or until the rings are lapped to fit the cylinders. The Peerless lapping tool for any size costs 50 cents. The extra disks per pair are 25 cents and the piston ring lapping compound is 25 cents.—Peerless Piston Ring Co., Newark, N. J.

Michener Valve Grinder

This tool consists of a steel shank with a spiral twist on which works an aluminum handle; moving the handle up and down causes the shank to turn first in one direction and then the other. At the top is a ball handle, of wood, with an anti-friction bearing, and at the other end a blade like that of a screwdriver to enter the slot in the valve head. Price, $1.50—E. S. Michener, New Castle, Pa.

Q. D. Tank Body

For quick oil transportation and for use with gasoline delivery wagons there has been put on the market a device known as the Q. D. or quick-delivery gasoline tank body for Ford cars. Oil companies whose service requires rapid delivery must provide a method of transportation of gasoline and oil which will quickly carry a supply to customers in emergency. This outfit is particularly designed to meet that requirement. A 100-gal. tank with extra cans of lubricating oil when required, as illustrated, provide a suitable load for the Ford car.

The tank complete can be attached the first time in about 2 hr., after that it requires not more than 5 min. to attach or detach it, thus providing a double-purpose car. The outfit is supplied with faucets, air vent, etc., and is used with or without box for measures, funnels, etc.—Ohio Welding & Mfg. Co., Cincinnati, Ohio.

Automatic Radiator Machine

Two automatic machines which have recently been shipped to the Coventry Motor Fittings Co. of Coventry, England, which are suitable for radiator manufacture, are illustrated herewith. The tube drawing machine will form tubing or molding in any desired shape from flat ribbon material. It will draw the tubing with plain or lock seam and is capable of drawing enough tube to make 200 automobile radiators a day.

The other machine is an automatic self-feeding punch press, taking the place of an ordinary press with roll feed, and, according to the manufacturer, is faster and more accurate than the latter. The machine is adapted to the manufacture of radiator fins, folding over the edge, perforating and cutting off, all in one operation. The self-feeding press will make enough fins or plates for fifty radiators a day.—F. H. Stolp, Geneva, N. Y.

Stolp radiator fin punch press

No-Glare Nitrogen Bulbs

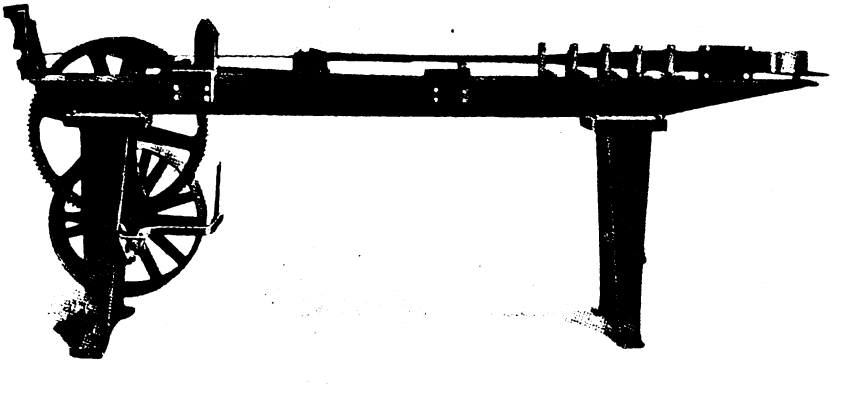
Opalescent nitrogen-filled bulbs are manufactured in 32-cp. and voltages to suit the various standard systems in use. The makers state that the lamp has been adopted by the States of New Jersey and Maryland and that it conforms with the anti-glare regulations of other States. Long life and high efficiency are claimed. Price, $1.—Vosburg Miniature Lamp Co., West Orange, N. J.

Maluminum for Parts

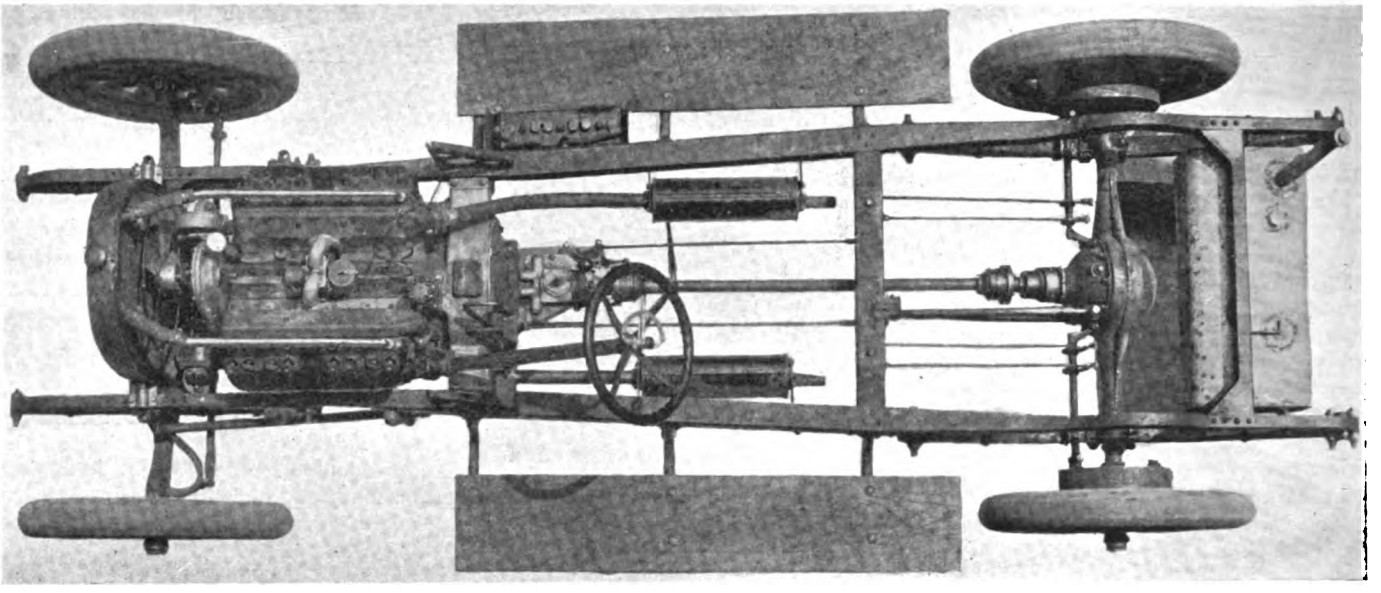
A malleable form of aluminum, called Maluminum has been developed for making car parts which must be light and strong. It is used for body molding, gearboxes, radiator frames, etc., and, according to the manufacturer, shows a tensile strength of 17,500 to 20,000 lb. per sq. in., and an elastic limit of about 16,000 lb. The metal is slightly heavier than some aluminum alloys now in use, but has the advantage that it is malleable, can be die cast and can be riveted in machine operations. It is also claimed that the metal is capable of taking a high polish.—Pioneer Brass Works, Indianapolis, Ind.

Grobet Spark Plug File

This file is designed especially to smooth the contact points of magnetos, coils and other ignition apparatus. It is claimed to cut smoothly without ripping or roughening the metal and without wasting platinum. The end of the file has a screwdriver point, the handle being round. The total length is 6 in., while the file surface is 3 in. long. The files sell for 15 cents each.—Montgomery & Co., New York City.



Stolp tube drawing machine for use in the manufacture of tubing for automobile radiators



Daniels eight chassis, showing mounting of unit power plant. Note twin exhaust manifolds and separate muffler for each cylinder block

Daniels Eight of Strong Construction

Uses Herschell-Spillman 3 1-4 by 5-In. Motor—Distinctive Body

AMPLE power is a characteristic of the Daniels eight, made by the Daniels Motor Car Co., Reading, Pa., which uses a 3¼ by 5-in. L-head Herschell-Spillman motor with Brown-Lipe gearbox in a unit power plant. The cylinders are cast in two blocks of four each with the inlet pipes integral and the exhaust pipes bolted on, the crankcase being an aluminum casting with the oil reservoir in the lower half; separate for easy accessibility. The valves are operated from a single camshaft with sixteen integral cams, or one for each valve. By staggering the cylinder blocks a distance equal to the width of the connecting-rod crankshaft bearing, the use of forked connecting-rod ends and of double concentric crankpin bearings is rendered unnecessary. The connecting-rods work side by side on crankpins and are interchangeable, being I-section drop forgings of two-bolt cap construction. The flywheel is of semi-steel with a machined steel starting gear ring bolted on. The formula rating of the motor is 37 hp. Twin exhaust lines and mufflers are employed.

Force-Feed Oiling

Lubrication is by force-feed, with regulation by a safety valve which discharges excess pressure of oil on the spiral gears in front that drive the camshaft and fan. Within the crankcase sump is located a geared oil pump which is driven by a vertical inclosed shaft and spiral gears. The crankshaft is drilled with oil passages and the connecting-rods are provided with oil pipes which permit the oil to be forced to the crankshaft, connecting-rod and piston-pin bearings. A Mayo cellular radiator is used for cooling in conjunction with duplex centrifugal pumps.

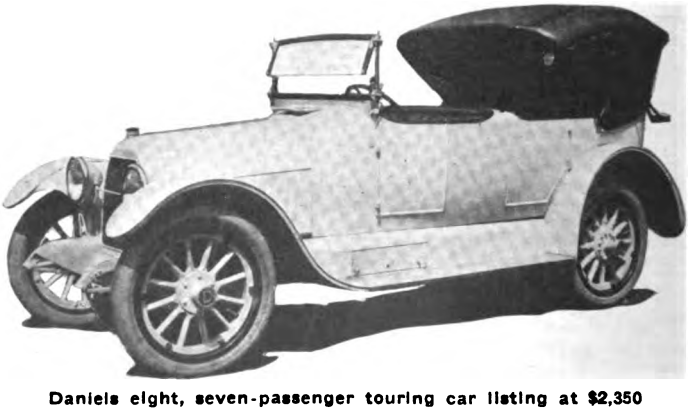
A 1¼-in. duplex Zenith carbureter is used with hot air intake and dash control for the strangler valve. Ignition is by the Westinghouse system in connection with a Willard 6-volt, 100 amp.-hr. battery, the interrupter being so constructed that the period of contact is practically the same at all speeds. The Westinghouse starter is also a feature in conjunction with a Bendix gear. The Westinghouse 6-volt generator for lighting and battery charging is driven by a cross shaft and spiral gears at the front of the motor. A vacuum fuel feed system is employed, the main tank having a capacity of 20 gal.

The three-speed Brown-Lipe gearset is secured to the motor by a bell housing, a multiple-disk, dry-plate clutch operating on ball bearings being used. The propeller shaft is equipped with a double universal designed to eliminate whip at highest speed. Drive is taken through the rear springs and torque through a torsion arm. Alloy steel, semi-elliptic springs are used, the rear ones being 2½-in. wide and slung under the axle.

Three-Quarter Floating Axle

A three-quarter floating rear axle is used, the shaft itself being of large diameter and the housing of pressed steel, other features of its construction being tapered roller bearings and spiral bevel gears. Brakes are of the conventional internal-expanding and external-contracting type, the drums being 15 in. in diameter.

Streamline design characterizes the body which has a double cowl finished with a heavy mahogany garnish around the top. Battery and tool boxes are set in the sides of the splash shields. With complete equipment the car sells for $2,350.



Daniels eight, seven-passenger touring car listing at $2,350

The Mid-West Section

BY organizing a Mid-West section of the Society of Automobile Engineers, which will embrace not only Chicago but such Mid-West cities as Milwaukee with more than fifty-seven members of the society, Moline, Davenport, Rock Island, Kenosha, Racine, Peoria, Aurora, Rockford, Whiting, Ind., the great gasoline center, and Gary, Indiana Harbor, South Chicago and Waukegan, the great steel centers, a broader scope has been given to the society, which will unquestionably prove of peculiar value within the next year or so. By christening it the Mid-West section this latest baby has set a new example in section organization, and has demonstrated how it will be possible to extend the influence of the society and make it more of a living organism in places too small to support a section, than it has been heretofore.

The big, broad gage conceptions of Chicago and the Middle West are ideally set forth in this new thought, and instead of holding all of the meetings in Chicago, by holding some in Milwaukee and perhaps others in Racine or Kenosha, it will be possible to open new vistas of opportunity. Essentially the Mid-West section is going to make practical meetings and demonstrations a major part of its program. It will be disappointing if the "I Will" spirit of the Middle West does not achieve marked success in this new phase of section policy.

The Front Fender Fallacy

NEW YORK CITY is being introduced to a front-wheel fender campaign for motor trucks and automobiles in which it is apparently pre-supposed by many of the city officials that the front-wheel fender on trucks and passenger cars is going to eliminate accidents, whereas statistics show that the front-wheel fender is not so great a necessity as the rear-wheel guard or fender. More pedestrians are run over with the rear wheels than by front ones, many of these accidents being due to pedestrians walking into the side of vehicles, the fault resting with the pedestrian rather than the truck.

It is doubtful if the front-wheel fender would be of any value to prevent pedestrians being run over by the front wheels because coroner reports from some of our largest cities show that where pedestrians are struck by the front end of a truck or passenger car that death generally results from concussion of the brain due to the force of striking the pavement, and that quite frequently the wheels do not pass over the victim.

Exports 5 Per Cent

AUTOMOBILE securities should not be classed as war stocks. The remarkable increases in value of some of them are not due to any great war business, but to general prosperity at home. Whereas, Bethlehem steel is strictly a war stock, General Motors, which has had nearly as sensational a rise, is not a war stock, for the company has not sold a single dollar's worth of war material from any of its plants in this country; according to an authoritative statement.

The enormous automobile business now being enjoyed is not due to the war. For the fiscal year ending with June of this year, the country had produced automobiles and trucks to the value of $525,000,000. During that time the records show that some $60,000,000 of automobiles and trucks were exported. This means that only about 10 per cent of the total business done in automobiles in this country was on an export basis. More than half these exports of gasoline vehicles were trucks, so that the quantity of passenger cars sent out of the country was not over 5 per cent.

Electric Progress

THE convention of electrical men interested in all angles of electric vehicle usage again shows, if indeed such demonstration were needed, that the electric field has much room for development. The electric taxicab has many points of advantage and Detroit's example may reasonably be followed by other cities. That electric vehicles have never been popular in European towns is due mainly to lack of interest on the part of central station men. In America better storage batteries, better vehicles and improved charging facilities are consolidating the electric's position and guaranteeing its permanence as a factor in national life.

Huff Chief Engineer for Dodge

Next President of S.A.E. Had Been With Packard Since Early Days

DETROIT, MICH., Oct. 19—Beginning Nov. 1, Russell Huff, consulting engineer of the Packard Motor Car Co. becomes chief engineer of Dodge Brothers. Almost from the time the first Packard car was brought out, Huff has been connected with Packard development. He was the right-hand man, from the engineering end, of S. J. W. Packard, when the latter was making his first cars in Warren, Ohio, about 1900. Ever since he has been one of the big engineers, not only of the Packard organization, but of the country. He is to be the next President of the Society of Automobile Engineers.

Biddle Co. Enters Field

PHILADELPHIA, PA., Oct. 18—The Biddle Motor Car Co., which has been newly formed, is preparing to place on the market a line of four cars, two of which are now ready. These are a touring car to sell for $1,880 and a roadster at $1,700. The third will be a town car, to sell at $3,000, and the fourth a car of the same type and equipped with a Duesenberg motor. The present chassis is designated series D and is equipped with a three-point suspended Buda unit power plant, with four cylinders, 3¾ by 5⅛. Ignition, lighting and starting are Westinghouse and fuel is fed from a Stewart vacuum tank. The wheelbase is 120 in. and tires are 32 by 4.

Phelps Dodge Advertising Director

DETROIT, MICH., Oct. 19—George H. Phelps who has been assistant to George C. Hubbs, assistant general sales manager of Dodge Bros. has been appointed director of advertising. He will have charge of all matters concerning the advertising department and also of sales promotion work.

Davenport Off for Europe

DETROIT, MICH., Oct. 16—E. W. Davenport, export manager of the Maxwell Motor Co. is en route for Europe to look after Maxwell business in Great Britain and on the continent.

Lee Counselman Re-enters Field

DETROIT, MICH., Oct. 18—After nearly one year of retirement from activities, Lee Counselman, who in November, 1914, retired from the Chalmers Motor Co. as first vice-president and general manager of the company, has now re-entered the active world and has become associated with J. T. H. Mitchell, Inc., advertising agents, with offices in New York and Chicago. He will be with the Eastern headquarters, which are at 8 West Fortieth Street, New York.

Mr. Counselman, is well known in the industrial world, and more particularly in the automobile industry, having been connected for seven years with the Chalmers Motor Co.

Paul Smith Chalmers V.-P.

DETROIT, MICH., Oct. 15—The board of directors of the Chalmers Motor Co. to-day elected Paul Smith one of the vice-presidents of the company, to fill the vacancy left through the retirement from the concern of Lee E. Olwell.

Mr. Smith has been with the Chalmers company since last June, when he joined in the capacity of sales manager and was also given charge of the service department. He was formerly sales manager of the old E-M-F and Lozier companies, and last year started in business for himself on the Pacific Coast.

Harrison Resigns from Chalmers

DETROIT, MICH., Oct. 14—H. R. Harrison has resigned as advertising manager of the Chalmers Motor Co. and has been succeeded by Gail Murphy, formerly with the Art Metal Construction Co., Jamestown, N. Y.

$2,200,972 in Cars and Trucks Shipped First Week of October

NEW YORK CITY, Oct. 20—Heavy increases in the shipments of automobiles and trucks to European ports are shown in a detailed comparative statement showing the values of the respective commodities shipped out of the port of New York for the week ending Oct. 9, 1915, issued yesterday by the foreign trade department of the National City Bank. The statement shows that the total shipment of cars and trucks was over thirteen times that made in the same week of 1914, the respective figures being $2,200,972 against $161,174. The 1915 figure consists of $1,017,647 in passenger cars and $1,183,325 in trucks.

The greater part of these shipments were destined to English ports, with France second in order and Italy third.

Scripps-Booth Price Unchanged

DETROIT, MICH., Oct. 18—In an announcement just made by the Scripps-Booth Co., manufacturers of the Scripps-Booth roadster, it is stated that there will be no reduction in price for 1916.

Car Factory for Rochester

CINCINNATI, OHIO, Oct. 16—A new automobile company, being formed by Harry C. Ebert, formerly with the Cincinnati Car Co., and a group of local capitalists. will build a factory at Rochester, N. Y.

Importers' Salon Jan. 3-9

Number of Exhibitors at Hotel Astor Expected To Be as Large as Last Year

NEW YORK CITY, Oct. 20—The Automobile Salon in which several makes of foreign-made cars will be put on exhibition, will be held Jan. 3-9 in the Grand Ball Room of the Hotel Astor as heretofore.

The 1916 Salon will be conducted as usual by the Automobile Importers' Alliance, of which E. Lascaris is president; T. E. Adams, vice-president, and S. J. Kjeldsen, secretary. Mr. Kjeldsen will again manage this exhibition.

It is expected that the number of exhibitors will be on a par with last year's event which had nine foreign car manufacturers, three body builders, three tire makers and two American car makers. Allotment of space will be made in about ten days.

To Build Gersix Truck

PORTLAND, ORE., Oct. 18—The Gersix Co. which is headed by Edward E. Gerlinger, and which will produce an assembled truck rated at 2½ tons capacity and selling for $2,500, has secured a lease on the building formerly occupied by the Pierce-Arrow dealer, a two-story brick structure at East Third and Oregon Streets. A feature of the truck will be a six-cylinder Buda motor. It is stated that during the past week, orders for equipment totalling $175,000 and including 100 sets of Westinghouse starting and lighting apparatus, 100 Buda motors and a quantity of Sheldon worm gears and axles have been placed. In addition to assembling trucks, the company will also rebuild and sell used trucks.

Larrabee-Deyo to Build Two-Ton Trucks

BINGHAMTON, N. Y., Oct. 15—A new concern known as the Larrabee-Deyo Motor Truck Co., has been incorporated in this city with a capital of $80,000 for the manufacture of 2-ton trucks. This company is practically a re-incorporation of the Sturtevant-Larrabee Co., which has made wagons and sleighs in this city for the past forty years. The manufacture of the trucks will start at once.

Brown Joins Perfection Spring

DETROIT, MICH., Oct. 15—Ralph Brown, who was chief engineer of the Keeton Motor Car Co., and also the American Voiturette Co., later joining the engineering force of the Hupp Motor Car Co., is now a member of the engineering force of the Perfection Spring Co.

Page New Departure President

Elected by Directors to Succeed A. F. Rockwell, Founder of Company

BRISTOL, CONN., Oct. 19—*Special Telegram*—DeWitt Page was elected president of the New Departure Mfg. Co. of this city as successor to Albert F. Rockwell, founder of the concern, at a meeting of the board of directors held here late this afternoon. Mr. Rockwell retains his interest in the company but retires from its active management.

Houghton Enters Truck Field

MARION, OHIO, Oct. 16—The Houghton Sulky Co., this city, announces that it will start building 1-ton trucks, which will be designed principally for delivery purposes. It is to be known as the Houghton truck and the first of the trucks will be on the market about the first of the year. L. R. Wottering is the engineer in charge of the designing department.

The truck will be equipped with a four-cylinder motor developing 22 hp. It will have three speeds forward and a floating rear axle especially constructed to take care of overloads. The wheelbase will be longer than on most light trucks.

Republic Rubber Makes Changes

YOUNGSTOWN, OHIO, Oct. 15—As a result of certain changes recently effective in the working organization of the Republic Rubber Co., L. T. Peterson, first vice-president of the company, takes charge of all factory operation; A. H. Harris will occupy the position of manager of works and W. D. Morris takes charge of all tire departments.

During the month of September the company's output of tires exceeded by more than three times its similar output during September of last year. The output of this department during each of the three preceding months was more than double what it was during the same months of 1914. The production during October, up to this date, has exceeded anything in the history of the company.

Adult Must Accompany Child Driver

MADISON, WIS., Oct. 16—Accompanied by an adult person, whether or not such adult is competent to run an automobile, a sixteen-year-old boy or girl, or one younger, may run an automobile on the public highways of this State, according to an opinion recently given by Attorney General Owen to District Attorney G. H. Putman of Waupaca county.

The question arose over interpretation of the law which provides that no person under sixteen years of age, unaccompanied by guardian or other adult person, shall be permitted to ride or drive an automobile upon the public highways.

Attorney General Owen says there can be no other construction than that intended by the Legislature. The presence of an adult person, he states, would act as a deterrent of reckless driving or speeding and that it makes no difference who the adult person is or what his or her ability to drive an automobile.

Klingensmith Succeeds Couzens Nov. 1

DETROIT, MICH., Oct. 14—Frank L. Klingensmith, will, beginning Nov. 1, occupy the chair left vacant by the withdrawal from the Ford Motor Co. of James Couzens, who, as was reported briefly in last week's issue of THE AUTOMOBILE was vice-president, treasurer and general manager of the Ford Motor Co.

Mr. Klingensmith is at present secretary of the company. This position he will relinquish and Henry Ford's son, Edsel B, a young man of less than 24, will become secretary of one of the biggest and most prosperous industrial organizations in the world.

It might be added that about twelve or fourteen years ago Mr. Klingensmith was receiving $10 or $12 a week.

Couzens Out of Canadian Ford

FORD, ONT., Oct. 15—The resignation of James Couzens as vice-president of the Ford Motor Co., Detroit, also means his retirement from the Ford Motor Co. of Canada, Ltd., of which he was also vice-president. He has been succeeded by Gordon M. McGregor, who has been secretary, treasurer and general manager of the company and who will continue to act as treasurer and general manager, while assistant manager W. R. Campbell has been promoted secretary.

To Abolish Wheel Tax

LINCOLN, ILL., Oct. 16—Lincoln will shortly abolish the offensive wheel tax which requires all automobile owners to pay a city tax as well as one to the State. The city council this week received a petition with 1000 names, asking that the ordinance be repealed and as the sentiment is so strong in this direction, the council will act in accordance.

Sterling Auto Mfg. Co. to Exhibit

NEW YORK CITY, Oct. 18—In the list of exhibitors for the New York and Chicago shows appearing in THE AUTOMOBILE last week appears the name of the Sterling Motor Car Co., Brockton, Mass. This should have been the Sterling Auto Mfg. Co., New York City.

Stutz Quits Racing Indefinitely

Retires After 5 Years of Successful Competition on Road and Track

INDIANAPOLIS, IND., Oct. 17—After five years in road and track races, the Stutz Motor Car Co. has announced through its President Harry C. Stutz that it will quit the racing game indefinitely. In an interview Mr. Stutz stated that the company may quit for six months and then again it may be out of the game six years, or forever, depending on future developments.

Burman in Blitzen Benz to Try for Records at Sheepshead

NEW YORK CITY, Oct. 15—Harry S. Harkness has bought the Blitzen Benz from S. A. Fletcher of Indianapolis. Bob Burman, its driver in the Ormond Beach record trials, will pilot it at the Sheepshead Bay Speedway on Election Day, where he will attempt to set up new records for a circular course.

Ward Special Averages 70 Miles Daily

CLEVELAND, OHIO, Oct. 15—The Ward Special which left the New York Electrical Show at its opening bound for this city, arrived here to-night. The distance traveled between New York and Dunkirk was 554.6 miles, a daily average of almost 70 miles. Erie was reached Thursday night and the noon stop yesterday was made at Ashtabula, where the battery was given an hour's boost.

Atlas Forge to Add

LANSING, MICH., Oct. 16—The plant of the Atlas Drop Forge Co. is to be considerably enlarged, the stockholders having approved a contemplated expenditure of $40,000 to $50,000 to that effect. The present force of 140 men is to be doubled. At a recent meeting of the stockholders a 10 per cent cash dividend on the company's capital stock of $200,000 was declared.

Puritan Machine Gets Owen

DETROIT, MICH., Oct. 18—The Puritan Machine Co., which recently purchased the stock and parts of the Havers Motor Car Co., Port Huron, has just taken over the stock, and parts of the Owen Motor Car Co.

Splitdorf Gets Foreign Contracts

NEWARK, N. J., Oct. 16—The Splitdorf Electrical Co., this city, has received contracts for equipment for its Dixie magneto for the English Daimler, the Italian Fiat and Isotta, and the Renault.

E. V. A. A. Holds Successful Convention

Many Subjects Discussed—Get-Together Between Electric Vehicle Makers and Central Station Interests Advocated—Over 200 Present

CLEVELAND, OHIO, Oct. 18—Two hundred electric vehicle manufacturers, central station men and others representing allied branches of the Electric Vehicle Industry, are here to-day at the opening of the sixth annual convention of the Electric Vehicle Association of America, at which the keynote was the marked improvement in the co-operation between the vehicle makers and the central station people, with a view to a more general use of electrics in all kinds of service. The electric interests have all come to realize that they are not obtaining the recognition which the performance, economy and general utility of electric cars deserves, and the convention evidently intends to get at the root of the trouble and to rectify it at once.

Co-operation Wanted

Nearly every speaker of the day mentioned this co-operation in one way or another, and they were practically unanimous in their belief that this is the salvation of the business. Station men and makers must get together for their mutual benefit: It is still largely a question as to how far one faction must go in its assistance of the other.

Undoubtedly the most interest to-day centered around the talk by George H. Kelly, (Baker, R. and L. Co.) on the problems the electric vehicle industry is facing and how they may be met, and also the report by Chairman Walter H. Johnson of the central station co-operation committee, the remarks of both men being allied in that they struck the same sympathetic note of co-operation. Mr. Johnson's remarks were recommended for circulation throughout the country because they represent so well the views of the gathering.

It was the sentiment that central stations should maintain electric vehicle departments and use electrics wherever possible, although it is inadvisable to try to make them use such cars when other types of vehicles obviously pay better. It was brought out that the only way to make the co-operative idea pay is to reach the central stations which have not already been brought into line.

Progress Made in 1915

Mr. Kelly said that the past year has shown marked development in the co-operation between the different branches of the industry, but the two great problems are the creating of electric car demand, and how to care for the cars after they are sold. He said, that the electric car answers the service demands of 99 per cent of the people in cities, as it has greater speed than any city will permit, and its mileage possibilities are more than any one wants. These are the two big features on which the public must be educated and convinced. The tremendous problem, he said, is how to show the pubilc of what the electric is actually capable. First the electric vehicle people must sell themselves on the merits of the cars, and then the rest will follow.

Electric Taxicabs Coming

The electric taxicab received a great deal of interest, Mr. Kelly predicting, that in five years it will have completely displaced the gasoline type. I. S. Scrimger, Detroit Taxicab & Transfer Co., which is the pioneer in this field, gave some information regarding the successful operation of such vehicles, and the interest shown may be taken as most significant of the development that is to come.

Two cars are here after long cross-country runs, demonstrating that electrics can be run long distances. The Ward electric successfully made the 740-mile run from New York without mishap, and one of the Detroit taxicabs was driven from Detroit.

1916 Officers Appointed

CLEVELAND, OHIO, Oct. 19—Business sessions of the Convention were closed following the election of officers for the ensuing year. These will be as follows:

President, W. H. Johnson, Philadelphia Electric Co., Philadelphia; vice-president, E. S. Mansfield, Edison Electric Illuminating Co., Boston; treasurer, H. M. Edwards, New York Edison Co. Directors, W. H. Blood, Jr., Stone & Webster, Boston; P. D. Wagoner, General Vehicle Co., Long Island City; G. H. Kelly, Baker R. & L. Co.; J. F. Gilchrist, Commonwealth Edison Co., Chicago.

The incoming administration is therefore represented by four central-station men and two vehicle manufacturers. The attendance was over one-fourth central-station representatives and one-seventh car manufacturers. The keynote of to-day's business was the favorable reception of an invitation given by E. A. Lloyd, president of the National Electric Lamp Association, for co-operation with that body with possible future affiliation as the result. The discussion Tuesday emphasized the fallacy of trying to sell electric trucks for service better adapted to other types of vehicles, and the central station was designated as the most valuable influence in persuading municipalities to adopt electric vehicles. There was considerable interest in the new battery rental schemes that are coming into vogue, many seeing in this movement a helpful factor in relegating the most annoying battery worries to the discard.

Of the papers presented to the meeting all had special interest for different classes of membership, and two which bear particularly on the manufacturing end of the automobile industry are reprinted in but slightly abridged form below.

Why Electric Taxicabs Should Succeed

By I. S. Scrimger

Electric taxicabs were first considered by the Detroit Taxicab & Transfer company about two years ago, although, personally, I had considered the matter two years prior to the time my company took the proposition up.

I think everyone in the taxicab business will bear me out when I say that the life of a well made gasoline car in a hard service, such as the taxicab business is, could not be much over five years at the outside. My judgment is that a gasoline car to perform satisfactorily will cost $2,000 to $2,500. Using the five-year period as the maximum as the life of the gas car, it means that a taxicab company is replacing their equipment every five years.

In Detroit, we get 70 cents for our first mile and 40 cents for each additional mile; single tariff meters being used. In other words, it doesn't make any difference as to the number of passengers carried, whether one or four—the capacity of the cab—the rate is the same. Comparative figures between the Detroit Taxicab & Transfer Company and other companies in the United States show that the cost of operation per mile is between 30 and 35 cents. Taking the 30 cents per mile cost as the basis for figuring, if a cab covers 2 miles we receive $1.10. If the cab returns empty, we have covered a distance of 4 miles for

which we have received $1.10. The cost per mile being 30 cents shows that we have lost on this run, and the history of the taxicab business throughout the United States is that from 40 to 50 per cent of our distances covered are empty mileage. The revenue obtained from service rendered in Detroit is about 33 cents a mile. You will, therefore, see that very little profit is to be made with an expense of between 30 and 35 cents a mile and an income of 33 cents a mile. It, therefore, became necessary that we obtain equipment that could be operated more cheaply than gasoline cabs.

First Cab Successful

About two years ago, we decided to build one electric cab as an experiment, and the president of this company and myself consulted with the manufacturers of electric vehicles in Detroit, but they were all too busy to give us much thought, and claimed they could do nothing for us unless we were willing to accept the chassis for the pleasure car they were building. The taxicab business being a commercial business, we could see how a pleasure electric car could be made to serve our purpose. We, therefore, were compelled to build our first car. This we did under the supervision of our engineer, Mr. W. J. Behn. Our first car was placed in service at the Hotel Ponchartrain at 2 o'clcock in the afternoon, June 25, 1914, and up to the present time has been in continuous service about a year and three months. No advertising was done, nor an announcement of any kind made when this cab went into service. We thought it best to start the electric service, and allow the public to judge whether or not the electric cab would meet all requirements. It was only a short time when we commenced to receive letters of approval, and the cab met with such a signal success that we decided to build eleven more. These additional eleven electric cabs went into service last December and January, and have, therefore, been in service about eight months. We are just completing fifteen additional electric cabs, which will be completed between now and the 15th of October, and we have twenty more under way, which will be in service about the 1st of January. This will give us an equipment of forty-seven electric cabs.

Cab Field Neglected

It seems to me that the manufacturers of electric vehicles have not kept pace with the manufacturers of gasoline vehicles. I mean by this that the public demand better mileage and better looking cars than those that are now in service throughout the country. One of the first questions we are asked is—how many miles can you get on ane charge, and then—how fast will they go?

All of our twelve cabs now in service are being operated 24 hr. a day with two drivers; each man working 12 hr. To enable us to operate our electric cabs 24 hr. a day, we have had installed at the edge of the sidewalk at the Hotels Statler, Tuller, Griswold House, and Ponchartrain charging boxes, and our cabs, while standing idle, are on charge. The Edison Illuminating Company of Detroit have co-operated with us in every way possible, and has given us power wherever it was possible to do so.

We feel that we have constructed for our service a thoroughly up-to-date, practical electric taxicab. Some eight years' experience with the gasoline car taught us the weak points of the gas car, and we have tried to overcome them with our new construction.

Our cab has a 121-in. wheelbase, and the interior of the cab body proper has a space about 68 in. long and about 50 in. wide, which you will see enables us to carry from four to five passengers very comfortably. Our experience taught us that the limousine type of body was preferable to the landaulet type, and could be operated with less expense. We are using Silvertown Goodrich pneumatic tires, and have already made a wonderful mileage showing with these tires.

In conclusion, our operating cost per mile up to the present time has not exceeded 20 cents a mile. This cost includes drivers' wages, overhead, tire expense, garage expense, depreciation and every expense in fact which is incidental to the operation of the taxicab business. The only point on which we are uncertain is the life of the car. We feel that the car has been so well made that we may be able to depreciate this car over a period of ten years. This, of course, is a problem which time alone will tell whether or not we are correct.

Performance of Gas and Electric Trucks

By William J. Miller and Stephen G. Thompson

One of the many favorable arguments advanced by the electric vehicle salesman in his efforts to combat the more popular gasoline machine has been that in its field of application this type of vehicle can accomplish practically as much in a day as can the higher speed gasoline machine, and do so at a less cost.

This paper is compiled with the purpose of developing the statement from one of theoretical assumption to one of scientific fact substantiated by practical demonstration; and to do this clearly, recourse to several charts has been made, which not only makes for brevity in the paper itself but has the advantage of concise presentation.

In pursuing this argument several factors must first be ascertained, and their relation to the subject as a whole weighed to determine all the contributory causes for the existence of the belief at all. Of these factors the important ones are:

1. The speed of acceleration and of deceleration of the gasoline machine;
2. The speed of acceleration and of deceleration of the electric machine;
3. The probable frequency of stops expressed in stops per mile;
4. The effect of other traffic on the highway as it relates to stops and speeds;
5. The total time available for running the vehicle.

This last is so important that it might be the determining factor in deciding whether to use power wagons at all, because with a relatively high standing time the advantages of power wagon operation over those of horse-drawn vehicles entirely disappear, as the proportion of the day when the machine is running is insufficient to make an appreciable reduction in the total running time; hence the machine can do no more work.

Now, returning to the several factors bearing upon the subject in hand, the first two, relative to the speed of acceleration and deceleration of the gasoline and electric machines, are shown in the following:

TABLE I

Elapsed Time in Seconds	Speed M.P.H.		Total Distance Traveled (ft.)	
	Gas	Elec.	Gas	Elec.
1.....	1.5	2.5	1.10	1.84
2.....	2.0	4.2	4.40	6.98
3.....	4.4	5.4	10.03	14.33
4.....	4.4	6.0	16.79	22.78
5.....	5.0	6.6	23.84	32.04
6.....	5.6	7.2	31.63	42.33
7.....	6.8	7.6	40.59	53.35
8.....	8.4	8.0	51.61	64.81
9.....	9.0	—	64.39	——
10.....	8.8	—	77.43	——
11.....	8.5	—	90.10	——
12.....	9.6	—	103.51	——
13.....	10.6	—	118.79	——
14.....	11.2	—	134.96	——
15.....	11.5	—	151.79	——
16.....	11.8	—	168.91	——
16 2-5...	12.0	—	186.50	——

This shows a series of observations on the acceleration and deceleration of gasoline and electric trucks of equal load capacity and quality made under identical operating conditions, the gasoline vehicle, however, having a speed capacity of 50 per cent in excess of that of the electric.

It will be observed that for the first eight seconds of acceleration the speed of the electric machine exceeds that of the gasoline, at which time it has reached its maximum, and that the acceleration of the gasoline machine to a speed 50 per cent higher than that attained at this point requires practically the same time in seconds, the elapsed time, speeds in miles per hour and distance traveled for each type of machine being as follows:

Table II. is a record of a series of observations on a delivery service in a city

of 750,000 inhabitants and the surrounding towns, operating within a radius of 15 miles of the business center.

For purposes of segregation the statistics are charted in zones according to the mean distance from the delivery route to the store. The mean distance is one-half the sum of the distance from the store to the first delivery stop and from the last delivery stop returning to the store. The characteristics of the zones may be given as follows:

Zone 1—Business and city residential apartment house sections;

Zone 2—Residential apartment houses and flat sections;

Zone 3—3-apartment flat sections and private houses;

Zone 4—Private houses in suburban towns.

This Table II. requires close analysis, as in it is contained the factors controlling the operation of a delivery system and limiting the movement of the vehicles employed. These factors are here emphasized, as they are those usually overlooked in the ordinary course of power wagon application; and because they are overlooked the popularity of the gasoline machine sways the buyer toward it regardless of the practicability of its application.

These important contributory factors are enumerated in the title heads of the table, and establish the following:

1. Probable average stops per mile:
   Zone 1.....6 Zone 3.....5
   Zone 2.....7 Zone 4.....4

2. Time elements in proportion to the total consumed, as follows:

Time running on route..... 29.86 per cent
Time running off route..... 17.76 per cent
Time delivering..... 28.18 per cent
Time loading ..... 24.20 per cent

3. Relative values of the "miles off route" and the "miles on route" 36 per cent and 64 per cent respectively.

With all of this accumulated data, we have established the factors affecting the speed of movement as it relates to the total day's work performance of gasoline or electric machine, and by applying these to the different zones the efficiency of the two types of vehicles may be determined. Therefore, if we resolve all these factors to a comparative basis we will find that for equal work performance the gasoline machine will but slightly excel the electric, which difference is of little consequence when the time-saving effected is properly segregated into the different time elements of a 9-hr. day. For example, on the basis of the calculations in Table II, the time elements in a 9-hr. day would be as follows:

Time running on route... 2 hours 41 minutes
Time running off route... 1 hour 36 minutes
Time delivering..... 2 hours 32 minutes
Time loading ..... 2 hours 11 minutes

Of these only the first two are affected by the relative speeds of the machines, the first being partially governed by the frequency of stops and the second by the speed capacity of the machine.

On an average basis of six stops per mile and a daily work performance equal to that possible with the electric vehicle, deductions based upon the facts as presented in Tables I. and II. would determine the daily saving of gasoline machine over electric to be 73 min., which for increased performance must be segregated into the time elements as follows:

Time running on route..... 21.80 minutes
Time running off route..... 12.96 minutes
Time delivering..... 20.57 minutes
Time loading..... 17.67 minutes

It will be seen that all of the foregoing is based upon unimpeded traffic when the machines are able to reach their maximum speed between stops and when running off route. Now if we qualify these figures with a consideration of the effect of traffic stops and slow-moving traffic, we then find that this apparently increased efficiency of the gasoline machine will almost entirely disappear. For proof of this we have the record of 100 days' observation of two gasoline and two electric trucks of equal capacity operating in the service of the Central Stamping Company between Newark, N. J., and New York City. Here it was found that the gasoline machines could attain an average of only 58 per cent of its maximum speed, while the electric maintained 72 per cent of its maximum possible speed. Expressed in miles per hour, this amounted to 6.1 miles for the gasoline machine and 5.8 miles for the electric.

The value of this increased speed, or, for that matter, the increased efficiency as deducted in our calculations, is rather questionable when the cost of obtaining it is considered.

Table II

	Mean distance to route	No. of stops	Miles on route	Miles off route		Approx. stops per mile on route	Time factors					
							Running		Del'y min.	Load min.	Total	
				Out	In		On route min.	Off route min.			Hr.	min.

Continental 100% Stock Dividend

Motor Co. Increases Capital —$500,000—Surplus $500,000 Over 1914

DETROIT, MICH., Oct. 20—*Special Telegram*—At a stockholders' meeting held yesterday it was decided that the capital stock of the Continental Motor Manufacturing Co. be increased $500,000 or to $2,900,000. A stock dividend of 100 per cent was declared. The surplus for the fiscal year ending June 30, was over $1,200,000 or $500,000 more than in 1914.

10,548 Cars in Spain

MADRID, SPAIN, Oct. 16—The total number of private automobiles registered in Spain on Jan. 1, 1915, was 10,548. The Province of Madrid led with 2405 registrations. The population of Spain is about 20,000,000, giving a car-to-population ratio of one in every 1896 people. These statistics serve to indicate a large field apparently practically untouched. This is brought out by comparison with the United States, where there are over 2,000,000 cars to 100,000,000 population.

No Gasoline on Sunday in Elizabeth City

ELIZABETH CITY, N. C., Oct. 15—Automobilists who travel to or through this city on Sundays will do well to investigate their supply of gasoline and lubricants; they will not be able to get these needed supplies on a Sunday. This has been decided by the Board of Aldermen which has passed an ordinance to that effect. The ordinance also applies to cigars, cigarettes and tobacco, and the only commodities which can now be purchased on the seventh day of the week, are, drugs, milk and ice cream.

Change in D. C. License Board

WASHINGTON, D. C., Oct. 16—The District of Columbia automobile board has ceased to be a separate branch of the local government and has been amalgamated with the license branch of the assessor's office. W. H. Coombs, license clerk, is designated as its secretary.

Wisconsin Cars Average $480 Value

MILWAUKEE, WIS., Oct. 16—The average value of automobiles in Wisconsin, according to the computation of the Wisconsin tax commission, is $480, compared with a valuation of $635.52 used in 1914. The greater number of cars now owned in the State is responsible for the decrease in average valuation. At the same time the average valution of a horse has decreased from $104.32 to $101.93; a cow, from $37.22 to $36.94; a hog from $12.69 to $10.58. At the decreased average valuation, the total valuation of motor vehicles, exclusive of motorcycles, has increased $4,887,152, and the grand total valuation of motor vehicles for the 1915 tax roll is $29,792,879. Only 66,847 motor vehicles of the 79,000 registered are actually assessed.

Bad Pavements Make Dimmers Hardship in Akron

AKRON, OHIO, Oct. 16—Following the police crusade against motorists who drive with undimmed or without lights, which resulted in the arrest of twenty-eight automobilists, directors of the Akron Automobile Club called a meeting to extend the co-operation of the club to the police in enforcing the ordinance.

In enforcing the dimmer ordinance, however, the club urged upon police the use of discretion in making arrests for, it was held, the streets of Akron are in such bad condition in many sections that lights stronger than 12-candlepower are needed in avoid accidents in passing over them.

Depreciation Table for Assessors

OLYMPIA, WASH., Oct. 12—To assist county assessors in valuing automobiles, the commission is suggesting the adoption of a uniform depreciation table. According to the table an automobile originally costing $500 has depreciated in value 10 per cent when first put in service, and is worth only $370 at the end of six months. For the second year its value is $320, for the third year $270, fourth year, $220 and fifth year, $170 and after five years $140. Similar rates of depreciation are adopted for cars of higher values.

Seventeen Cars Deliver Cleveland Mail

COLUMBUS, OHIO, Oct. 16—Seven automobiles replaced horse-drawn wagons in the transfer of mail to and from local railroad depots recently, when the new contract for this work went into affect. There are now seventeen automobiles engaged in carrying mails for the Columbus postoffice. But two single-horse wagons, delivering parcel post matter in the business district, are now used by the local postal department.

Postmaster Kinnear said the mails were out 30 min. earlier in the morning as the result of the difference in speed of the cars over the horses.

Hunt Stromberg Detroit Manager

DETROIT, MICH., Oct. 19—George H. Hunt, formerly connected with the offices of the Stromberg Motor Devices Co., Chicago, has been appointed manager of the Detroit branch.

25,000 in Safety First Federation

N. Y. Accidents Reduced 4790 in Nine Months Due to Society's Work

DETROIT, MICH., Oct. 19—At to-day's first session of the first annual convention of the Safety First Federation of America, after the introductory address by President Darwin P. Kingsley, who dwelt upon the subject of permanent world peace, the first annual report was read by Executive Secretary Frederick H. Elliott. It showed that the combined membership of the federation is now about 25,000. Statistics were read showing what the Safety First Society of New York had accomplished within the rather short period it has been in existence, one striking example given being that of the reduction in the non-fatal accidents in the streets of New York between Sept. 1, 1914, to May 31, 1915, during which period the new ordinance suggested by the society and which provides for near side stop for surface cars, has been in effect. During that time there were 4790 less non-fatal accidents than in a corresponding period before the ordinance went into effect.

Urges Examination of All Drivers

Harold W. Newman, commissioner of public safety of New Orleans, La., spoke on the subject, Necessity of Examining All Motor Vehicle Operators. He urged that not only be it compulsory for chauffeurs to be examined as to their fitness to operate an automobile, but said that it is just as important that every car owner and car purchaser should be compelled to undergo a thorough examination.

Furthermore, it is suggested by the speaker that only those who pass the examination successfully be permitted to drive a car. Such action should be country-wide.

Co-operation on Behalf of the Automobile Manufacturers was the subject of J. Walter Drake, president of the Hupp Motor Car Co., who spoke as the representative of the National Automobile Chamber of Commerce, Inc. The keynote of his talk was that what is and will always be most needed in the safety first movement as well as other campaigns for betterment, is education of the people rather than legislation.

Zimmerschied to Speak

To-morrow Karl W. Zimmerschied, chairman of the standards committee of the Society of Automobile Engineers, is scheduled to address the convention, his subject being: The Contribution of Automobile Engineers to the Movement for Public Safety.

Ford Surplus Gains $10,308,738.59 in 10 Months—$43,788,151.23 Cash on Hand

Fiscal Year Changed—Cash on Hand Increased $16,346,682.44 Over 1914—Total Assets Are $88,535,840.41, an Increase of $26,903,583.25 for Year

DETROIT, MICH., Oct. 14—The Ford Motor Co. during its 1915 fiscal year, which ended July 31, and extended over a period of only ten months, instead of twelve, as in 1914 and former business years, was able to set aside the extraordinarily large surplus of $59,135,770.66. This is an increase of $10,308,738.59 over the surplus at the end of 1914, $31,011,507.66 more than the surplus was in 1913 and an increase of $44,390,675.09 over the 1912 surplus.

Even more astonishing is the cash on hand or in banks, which totaled $43,788,151.23 at the end of last July, or ten months, while at the end of September, 1914, or for twelve months, the total was only $27,441,468.79 which means that in the ten months of the 1915 business year the cash increased by $16,346,682.44. In 1913 the cash balance was $13,225,710.82 and in 1912 it totaled $6,400,100.66.

The total assets for the past year amount to $88,535,840.41 or an increase of $26,903,583.25 over 1914. On the assumption that the fiscal year had been of twelve months instead of ten, the total assets might have reached the enormous sum of $103,291,814.41 and the surplus might have totaled $73,891,744.66.

$14,335,767.87 in Merchandise

Among the different items mentioned among the assets the biggest is that of merchandise, which means raw and finished materials or products, inventoried at cost. This account figures for $14,335,767.87 on the balance sheet, which is an increase of $5,051,318.61 over the total of 1914.

Buildings and building fixtures are next on the assets list with a total of $12,931,884.45 or an increase of $2,216,856 over the 1914 total. The factory equipment account shows an increase of nearly $950,000 for the past year while for machinery and power plant there is shown an increase of more than $1,800,000. Another big item is that of real estate, which now has passed the $3,100,000 mark, an increase of nearly one million over the total shown in 1914.

The biggest item listed under the liabilities is $15,000,000 being the buyers' profit-sharing reserve. This is in reality a part of the profits of the company, a part of the total surplus, which is being returned to the purchasers of Ford cars during the fiscal year because the Ford company announced at the beginning of the fiscal year 1915 that if 300,000 cars were sold during the year the buyers of these cars would receive a rebate of from $40 to $60 per car.

$15,000,000 in Rebates

Thus it might be said that the 1915 surplus was actually $74,135,770.66, but, after car No. 300,000 of the 1915 production had been sold, $15,000,000 of the year's surplus was no longer to be considered as such, and became a liability.

Other large items among the liabilities are those of accounts payable, which shows an increase of over $1,600,000 over the total of 1914; contract rebates, which more than doubled and contract deposits which show an increase of over $500,000 for the year. The reserve for depreciation of fixed assets also shows an increase of more than half a million.

The capital stock of the Ford company is still listed as $2,000,000 although it had been decided to increase it considerably.

Ford Company's Cash in Bank or at Hand Increase

Year	Total	Increase
1912	$6,400,100.66	.....

*The 1915 statement represents the business for only ten months because last year it was decided to change the end of the fiscal year from Sept. 30 to July 31.

Canadian Ford 50% Dividend

FORD, ONT., Oct. 18—For the third time this year a cash dividend has been declared by the Ford Motor Co. of Canada, Ltd. This time it is of 50 per cent, while on the two previous occasions the dividend was 10 per cent cash. As the capital of the company is $1,000,000 it means $500,000 for the shareholders, this time, or $700,000 all told this year. Most of the stock is said to be held by Henry Ford.

Car for Every 25 Persons in New Jersey

TRENTON, N. J., Oct. 15—One person in every twenty-five in New Jersey owns an automobile or is licensed to drive a car, according to the records of the State Department of Motor Vehicles. Approximately 115,000 persons are licensed to operate. On an average 300 persons are examined every week in Newark.

Car Sales in Norway Good

INDIANAPOLIS, IND., Oct. 19—Alf Neilsen of Christiania, Norway, who has arrived in this country and is interested in the sale of automobiles in Norway as the representative of the Cole Motor Car

Co., states that business conditions in Norway are excellent, and have been so since the beginning of the war. Sweden also is prospering. Both countries have been exporting supplies of various kinds, but in the past few weeks the exportation of foodstuffs have been discontinued, as it is necessary for them to conserve their resources.

In the automobile field prospects are very bright. The country is large and the number of cars is extremely small in proportion to the population. In the entire country there are only 1200 cars in use, and 200 of these are trucks. With the increased prosperity of Norway there is no doubt but that the sale of automobiles is going to reach a high water mark this year.

—

Bumper Wheat Crops Presage Good Sales in West

PORTLAND, ORE., Oct. 15—Bumper crops are reported in Eastern Washington and Eastern Oregon. The farmers of the great Inland Empire are inclined to hold their wheat for the high prices which were realized last year. Warehouses and granaries are fairly bursting with grain, but as soon as it begins to roll to market it is predicted there will be a stream of new automobiles rolling up the front yards of hundreds of farmers throughout eastern Oregon and eastern Washington, and in consequence the dealers located at Tacoma, Seattle, North Yakima, Spokane, Walla Walla and Pendleton, Idaho, are going to dispose of their entire allotment of cars.

The banks throughout that section are now much more favorable to the automobile industry than ever before for the reason that the automobile has become to be universally recognized as a necessity instead of merely a luxury, a necessity which is really more valuable to the out-of-town owner than to the city dweller.

—

Automobile Sales in Oregon Increase

SALEM, ORE., Oct. 12—Some interesting figures have just been compiled by Secretary of State Olcott, relative to the number of motor vehicles, chauffeur and motor vehicle dealer registrations from Jan. 1 to Sept. 30, inclusive. The total number of motor vehicles was 22,998 for the period, indicating that there was heavy automobile buying, and that it was largely increased over the same period in 1914, when 16,121 motor vehicles were registered. Chauffeurs increased from 1719 to 3804 and dealers increased from 109 to 171.

—

8600 Cars in Manitoba

WINNIPEG, MAN., Oct. 15—Manitoba is receiving upward of $100,000 this year from the automobile business. Licenses has already been issued for 8600 cars and probably 500 more applications will be filed.

100,000 Cars for Bay State

—

Registrations at Rate of 150 a Day — 19,346 Gain Over 1914—2914 More Trucks

BOSTON, MASS., Oct. 15—Before October is ended there will have been registered in the Bay State more than 100,000 motor vehicles. E. J. O'Hara, who has charge of the registration department, stated to-day that with the numbers being issued at the rate of about 150 a day there was no question about the figures quoted being reached.

In the number of vehicles there were 19,346 more registered this year than for all of last year. For the same period the trucks show a gain of 2914, the makers and dealers 193, the licenses 12,216, the renewals 7452 and the examinations 1308.

Naturally the increase in receipts has been correspondingly large, totalling $234,011.55. Before the year ends the State will have added enough more to make the total at least $250,000 more than last year. One of the most significant items is the fact that there were 1308 more examinations to date than throughout all of 1914, for it shows that the Highway Commission is doing its utmost with the force available to see that operators of cars have some knowledge of handling the machines.

The Commission has just finished taking its triennial highway census throughout the State, but the figures will not be available for some time. The census for October began last Sunday and lasted for a full week. There were 209 people keeping tabs on the traffic of all kinds for the entire week.

—

Churchward Leaves Gray & Davis

BOSTON, MASS., Oct. 19—Alexander Churchward, chief engineer of Gray & Davis, resigned Oct. 15. He will take a long vacation. It is stated that no change of policy will follow his resignation from the company.

—

Shelley of Packard Returns

DETROIT, MICH., Oct. 17—J. G. Shelley, inspector of trucks for the Packard Motor Car Co., has returned to Detroit after a year spent in Petrograd.

"The motor manufacturer of the United States has won world-wide fame for the sheer honest worth of his product and that will have a tremendous effect after the war ends," Mr. Shelley says. "The developments of the past year abroad have demonstrated more forcibly than anything else could, how greatly the world must depend on gasoline these days and the showing of the vehicles from this country has made them the standard of the earth for heavy duty hauling."

Fred Schaefer, another Packard employee who accompanied Mr. Shelley, will return from Petrograd within two months.

—

3139 Overlands Registered in Iowa from April Until August

DES MOINES, IOWA, Oct. 15—From April to August, inclusive, of the current year, 3139 Overland cars were registered in Iowa. In the month of July, 1140 Overlands were registered in the State. From Jan. 1 to September, 1914, the total number of cars registered in Lucas County, Ohio, amounted to 5264. Of this number 786 were Overlands. During the same period this year, 6830 cars have been registered, 1235 of which were Overlands. These figures show that 30 per cent of the total increase in cars registered in the county since Jan. 1, have been Overlands.

—

Patagonia Orders Detroiters

DETROIT, MICH., Oct. 16—R. T. Yeats, director of exports of the Detroiter Motor Car Co., Detroit, recently received an order for new Detroiter cars for shipment to Patagonia. This order will be routed via Buenos Aires and is finally destined for Trelew, Patagonia. The new Detroiter is now being represented in forty foreign countries and the sales effected have been remarkable since the re-organization of the company three months ago.

—

Overland May Change Fiscal Year

TOLEDO, OHIO, Oct. 14—At the annual meeting of the stockholders of the Willys-Overland Co. which will be held here Oct. 26, it will be proposed to change the end of the company's fiscal year from June 30 to Dec. 31. Other changes to be submitted for approval are that the annual meeting be held on the second Tuesday in May of each year, instead of

Bay State Registration Figures

	Jan. 1 to Oct. 1, 1914	Total, 1914	Jan. 1 to Oct. 1, 1915	Increase Over 1914

the fourth Tuesday in October, as now; that the number of directors be increased from seven to nine; that the officers elected by the directors annually shall hold office during the pleasure of the board of directors instead of for the term of one year; that there be a monthly meeting of the board of directors on the first Tuesday of each month without notice, in addition to the meetings now provided.

—

Cars Worth $181,576 Shipped from New York in September

NEW YORK CITY, Oct. 14—South America received from this port during the month of September, 1915, automobiles valued at $181,576. Of this amount $106,295 was for Argentina, with $33,739 for Venezuela and $16,248 for Chile. The rest of the countries ranged from $3,370 to $8,300.

—

Chevrolet to Build New Plant in New York

NEW YORK CITY, Oct. 15—The Chevrolet Motor Co. of New York has leased the entire block front on the east side of Eleventh Avenue between Fifty-fifth and Fifty-sixth Streets, fronting 200 ft. on each thoroughfare. The Chevrolet Motor plant now covers the block front directly to the north, between Fifty-sixth and Fifty-seventh Streets. The site will be improved with a modern factory and service building similar to the one it now occupies in this city. With the completion of the new building the facilities of the company will be more than doubled. The concern is also making large additions to its plants at Tarrytown and at Flint, Mich. Within a short time the company expects to be turning out 800 cars a day.

—

Goodrich to Insure and Pension

AKRON, OHIO, Oct. 16—Free life and accident insurance and a retirement pension will be given the 15,000 employees of the B. F. Goodrich Co., beginning Nov. 1. The free insurance and pension will be thorough, and applicable to every employee with no cost to him.

—

Van Sicklen Opens Detroit Office

DETROIT, MICH., Oct. 14—The Van Sicklen Co. speedometer makers, has opened a branch office and service station at 1255 Woodward Avenue, and C. P. Van Sicklen, son of N. H. Van Sicklen, president, has been placed in charge. The Van Sicklen Co. has also engaged Otto Von Bachelle, consulting engineer, who will be located in the Detroit territory. By opening its branch office here, the company has severed connection with the Cutting, Armstrong and Smith Sales Co.

Stewart-Warner to Add 275,000 Ft.

—

New Plant 7 Stories—Will Make Total Floor Area 445,000 Sq. Ft.

CHICAGO, ILL., Oct. 18—The Stewart-Warner Speedometer Corp. has started work on a new factory building, which will have a floor area of 275,000 sq. ft. as compared with the present plant, which has an area of 170,000 sq. ft. of floorspace. Instead of being an addition the new factory is much larger than the old, and will be a seven-story brick and concrete structure measuring 191 by 291 ft. and of U-shape. The new building is being erected alongside the old factory, the corporation having purchased property 125 by 286 ft. The work of razing the residences on the property in the purchase has already begun and it is expected that a city street which separates part of the property from the remainder of the corporation's holdings will be condemned and closed. The company at present employs 1200 men in its factory and hopes with the new building materially to extend its manufacturing facilities as well as its service system. When the new building is completed there will be a total floor area of 445,000 sq. ft.

—

Cleveland Employees Demand Eight-Hour Day

CLEVELAND, OHIO, Oct. 15—Three hundred employees of the Bardons & Oliver Machine Co. walked out this week. The men struck for shorter hours and more money. Further demonstrations were held at the Winton Motor Car Co. plant. The situation at the Warner & Swasey machine works remained the same—about 100 of 1200 employees working.

The specific demand is for an 8-hr. day at the 9-hr. rate, with time and a half for overtime.

—

Stearns Gives Ten-Hour Pay for Eight-Hour Work

CLEVELAND, OHIO, Oct. 15—Efforts to perfect union organization among 1000 employees of the F. B. Stearns Co.'s plant were stilled last night when it was announced that beginning Oct. 16, they will receive 10 hr. pay for 8 hr. work.

—

Chalmers Men Meet in Denver

DENVER, COL., Oct. 10—Twenty-five Chalmers dealers from Colorado and Wyoming towns were given a banquet last night at the Savoy Hotel by E. J. Johnson, Chalmers distributor for this territory. F. B. Willis, the company's sales manager, and J. M. Robbins, factory representative, gave talks on construction features and practical selling points, and several of the dealers reported upon trade conditions in their respective localities. These reports were all favorable for the season's outlook, and the meeting is counted upon to give the business in this district a substantial push forward.

—

3000 Detroit Electrics for 1916

DETROIT, MICH., Oct. 18—Between Aug. 1 and Oct. 1, the Anderson Electric Car Co., which makes the Detroit electrics, has sold 92 per cent as many cars as it sold during the entire year 1914. The business is increasing at such a rate that since Thursday, Oct. 14, a large force is working nights. At the present time the company has between 1400 and 1500 men on its payroll, the largest number in its history. The scheduled output for 1916 is 3000 passenger electric vehicles. The daily average production is now ten cars, but this will probably be increased to fifteen or more before long. An addition, 125 by 125 ft., has been made to the body department, and possibly other enlargements will be made necessary.

—

Hyatt Roller Bearing to Build

HARRISON, N. J., Oct. 15—The Hyatt Roller Bearing Co. has let contracts for an eight-story building, 75 by 200 ft., at Middlesex and Fifth Streets and Railroad Avenue, Harrison. It will be of the beam and girder concrete type with brick curtain walls and pilasters.

—

347 Studebakers a Day

DETROIT, MICH., Oct. 16—At the Studebaker Corp. all former production records were broken to-day when 347 cars were made. How soon this mark will be passed no one at the plant would dare say, but an official said that he hoped that 500 cars a day will be a matter of fact within the next sixty days.

—

$300,000 Tire Co. Formed

MARION, OHIO, Oct. 16—The Marion Tire & Rubber Co. has been incorporated with a capital of $300,000 to manufacture automobile tires. The incorporators are A. J. Barry, W. H. Holverstott, S. B. Lippincott, W. T. Jones, J. Leonard Price, W. F. Moyer and R. T. Lewis.

—

New Sanford Jitney Body

SYRACUSE, N. Y., Oct. 15—The Sanford Motor Truck Co., this city, has brought out a new body for use in interurban passenger traffic. This body is completely inclosed and is especially adaptable for jitney service.

Southern Enthusiasm for Dixie Highway Found at Every Turn

Trail Blazing Party Nearing Goal—All Kinds of Roads Encountered and Some Delay Caused By Mud and Mountains—Few Mechanical Troubles

NASHVILLE, TENN., Oct. 13—This was hoodoo day for the Dixie highway tourists, the ominous date bringing rain, mud, rough roads and a difficult 13 hr.'s run of 164 miles from Elizabethtown, Ky., to the capital of Tennessee. For the first time since the cars started on the long trek to Florida from Chicago, there was rain.

In addition to two water-soaked stretches, there was some rough going this morning in the southern part of Kentucky. The pike was hard enough but it had too much contour. The cars bounded over the outcropping stones which were laid almost a century ago as a foundation of one of the finest highways in the early days of the republic but a highway which lost most of its surface when the artillery and the munition wagons of the Union and Confederate armies rumbled over it. It was impossible to travel at a greater speed than 10 m.p.h.

However, money already has been voted for reconstruction and the work of repairing and resurfacing has been started.

Cars Stand Up Well

Because of the wet and rough going, the tourists were on the road for 13 hr., the longest day's run of the trip so far, the last 60 miles of the day's tour being covered in the dark. Nashville was not reached until shortly before 9 o'clock.

In the tour to date, three of the six State through which the Western link of the Dixie highway runs have been crossed and 658 miles of the 1800-mile trip have been covered. All nine cars have come through without any mechanical trouble and with few stops for tires, there being but one broken spring.

CHATTANOOGA, TENN., Oct. 15—Hawkins Cove is not in the geographies but the memory of its grades and terrors is indelibly stamped on the minds of the Dixie highway tourists who arrived here at 3.30 o'clock this morning after a tortuous 20-hr. ride from Nashville.

It was about 6 o'clock last evening that the motorists first were introduced to Hawkins Cove at the entrance of the Cumberland mountains. The road that passes through its dense timber and leads to the summit of the mountain is a spiral climb of 3 miles with an average grade of 35 per cent at least.

Only three cars made the top by means of their own power. Two mules rendered first aid to the other machines and pulled them up the steep slopes.

30 Miles in Dark

After the ridge of the Cumberlands had been reached and Hawkins Cove was behind, there was a 30-mile run in the pitch darkness over soft, narrow mountain trails that wound in and out among the dense pines. To make matters worse, the eight-cylinder Cole, carrying Judge M. M. Allison, president of the Dixie Highway Association, and other officials, broke a steering rod and a halt of more than 2 hr. to make temporary repairs was imperative.

Residents of Chattanooga waited all through the night and early hours of the morning to welcome the tourists to this historic city. The Dixie bound cars were met at Jasper's Ford, where the Tennessee River was crossed by means of a ferry, by a delegation from the local motor club.

At 4 o'clock this morning, a dinner-breakfast was served at the Patten hotel. The food had been on the fire since 6 o'clock the evening before when the motorists were scheduled to arrive.

In order to give the drivers an opportunity to overhaul their cars and permit the tourists to recuperate from their trip through the mountains, the officials have decided to lay over to-day in Chattanooga. We will take to the road again in the morning when the 140-mile run to Atlanta will be made.

Postponed One Day

This change in the schedule will make the tourists a day late at all the stops in Georgia and Florida, and Miami, the terminus of the tour, will be reached next Saturday, instead of Friday.

ATLANTA, GA., Oct. 16—Under the fairest of southern skies and over the convict-built roads of the Piedmont range of the Cumberland mountains, the Dixie highway tourists rolled through Georgia in triumph to-day and were feted all the way from Chattanooga to Atlanta.

At Rome, earlier in the afternoon, the tourists received a tremendous ovation and three miles outside of Rome 100 cars met and escorted them to the Berry School, a philanthropic institution where the sons and daughters of poor farmers are given an education, and the Shorter College, one of the most exclusive schools for young women in the South. At both places, there were showers of flowers, songs and speeches.

The demonstration was not sporadic, it extended all along the line from Chattanooga to Atlanta. La Fayette was en fete. The town looked as if it was circus day.

At Cartersville, on the afternoon trip from Rome, the cars were showered with chrysanthemums and a band blared a welcome. A welcome arch of cotton bales spanned the main street at Kington, a small village of about 500 residents. The motorists were bombarded with apples, flowers, cotton and boxes of candy at Acworth.

The roads through the foothills of the Cumberlands were easy to negotiate for most of them are hard and the grades are not steep. They are being worked by convicts at the present time.

—

Form Company to Further Trade Relations with Russia

NEW YORK CITY, Oct. 20—A joint sales company to operate in Russia and to further the trade relations between the United States and that country is the object of the International Manufacturers' Sales Co. of America, recently organized with headquarters in Chicago and branch offices in New York City and Moscow. A. S. Postnikoff, for many years connected with the International Harvester Co., and who has had wide experience in Russia, heads the new company. The capital stock of the company will be issued to the amount of $100,000, to be held in parcels of $2,000 each by fifty manufacturers of this country, engaged in non-competing lines. In return for this subscription the company engages to handle the export business of the manufacturers. Not only will they receive the profits from the sales of their own products but will also share in the joint profits of the selling organization.

—

Ultimatum on St. Louis Headlights

ST. LOUIS, MO., Oct. 16—The local police department recently issued an ultimatum to every owner of an automobile or motor truck calling upon him to submit the headlights of his machine to the Municipal Bureau for adjustment before Oct. 20. After that date, the Chief of Police has ordered the arrest of every automobile driver the lights of whose machine do not conform to the letter of the recent ordinance against dazzling headlights. This order results from the fact that only 20 per cent of the automobile owners of St. Louis have brought their machines to the Shadow Box at the City Hall, which has been available to them without charge for more than a month.

The police and street department officials are discouraging the use of dimming devices and point out that the new ordinance limits only the direction of the light's rays, not their intensity.

Texas Gasoline Cos. on Grill

State Attorney Claims Consumers' Prices Not Based on Supply and Demand

AUSTIN, TEX., Oct. 19—The State Attorney General's Department which has been conducting an investigation into the gasoline and crude oil situation, with particular reference to the alleged fixing of prices of these products and controlling the output, in different cities and producing field of Texas, claims to have discovered evidence that shows that the actual available supply and demand has little to do with the prices that are charged the consumer. The fact that gasoline prices in Austin and other cities of the State steadily mounted upward during the last four months from 10 cents to 17 cents per gallon and that each advance was made simultaneously by practically all dealers led to the conclusion that a combination was back of the trade. This belief has been fully substantiated, according to the statements of representatives of the Attorney General's Department who conducted the investigation. Already the price of gasoline has dropped from 1 to 3 cents per gallon in San Antonio, Austin and other towns and cities of Texas. These reductions were due, it is said, to the activities of the Attorney General's Department. It is reported on trustworthy authority that preparations are being made by Attorney General B. F. Looney to file suit against all of the Texas refining companies for heavy penalties and for forfeiture of their respective charters for alleged violations of the anti-trust laws in fixing the price of gasoline.

Boost Crude Prices

The reason which the refiners give for raising the price of gasoline is that production of crude oil has materially decreased. It is alleged by the Attorney General's Department that the refiners own the crude oil supply, including the producing wells and that when they want to boost prices of the crude product and gasoline they cap the wells and thus bring about a decrease in the output.

—

Portland Gasoline Up Two Cents

PORTLAND, ORE., Oct. 12—Within the past fortnight the price of gasoline in Portland and Multnomah county has advanced 2 cents and the indications are that the end is not in sight. Some of the wisest heads are now declaring that the price will ascend gradually until a retail figure of 18 to 20 cents is reached.

Until two weeks ago gasoline was wholesaling at 9½ cents in Portland. Several of the cut-rate houses were then retailing at 10 cents a gallon, while the filling stations operated by the wholesale companies were commanding a retail price 2 cents in advance of the wholesale figure. Then the wholesale price was advanced a cent and the retail price experienced a similar advance.

Last week orders came for another penny increase, making the wholesale price 11½ cents. The retail prices now vary all the way from 12 cents to 13½ and 14 cents.

—

Few Market Changes

NEW YORK CITY, Oct. 19—Markets this week were dull and very few changes occurred. There were three gains and three losses. The heaviest gain took place in the metal markets. The heavy sale of tin which has been going on during the last few weeks has made tin advance to $33 per 100 lb., making a total gain of 25 cents. Antimony is firmer and slightly higher with a better demand. Holders are asking 28 and 28½ cents for spot duty paid. Aluminum, which had all week been holding at a good advance, yesterday was somewhat easier, there being sales of spot at 50 and 55 cents in ton lots. Copper is firm, the asked price being 18 cents for both electrolytic and lake in ton lots only. The steel markets are dormant, there being very few sales made and no changes in prices.

A somewhat better demand was reported for some grades of crude rubber, though there was no snap to the trading. Despite the activity in the rubber markets, manufacturers seemed to want only small lots. Up-River Para fine quoted at 57 cents. The oil and lubricants markets were not very active last week. No changes took place although the trading conditions were a bit more normal. The demand for naphthas continues active and the market retains a firm tone. No changes were reported in crude oil quotations. In the animal oils market trading was more active, inquiries for moderate quantities being received. Prices continued to rule steady. Mineral lubricants market was also active with many buyers on hand. The prices continued the same. Although gasoline has made no further advance it is expected to rise within a short time, making the price per gallon 25 cents.

Eight per Cent Dividend for Unsecured Detroit Body Creditors

DETROIT, MICH., Oct. 16—Unsecured creditors of the Detroit Body Co., are now receiving a first dividend of 8 per cent, and it is possible that a further payment will be made later. Thus far the trustee has paid claims amounting to $211,691.18. After the appointment of the Security Trust Co. as trustee, May 8, 1915, the Fisher Body Co. made an offer of $170,000 for the bankrupt concern's plant and materials. This offer was 70 per cent over the appraisal value, and, was accepted after a public auction at which no higher bid was made.

—

Chalmers Stock Listed

NEW YORK CITY, Oct. 15—Chalmers Motors stock has been admitted to official trading in the outside securities market in this city. The common stock has paid $10 per share for several years. It is expected that the company will earn at least 30 per cent for the $5,000,000 in common stock this year. This stock heretofore has been traded on the Detroit Exchange, and is now listed also on the Philadelphia Exchange.

Studebaker War Order Profits $20 a Share, Common

DETROIT, MICH., Oct. 16—The Studebaker Corp., by the end of the current fiscal year, Dec. 31 next, will have completed well over $20,000,000 of war orders, on which profits are expected to amount to over $20 per share of common stock outstanding.

Domestic business is running more than double that of a year ago. The 1916 schedule calls for 70,000 cars for domestic use and 6,000 for export. This compares with an output in the past year of about 40,000 cars. Production in 1914 by Studebaker was 36,430 cars, and in 1913, 32,504 cars.

For the calendar year 1915, it is expected that common share earnings will be over $35. The stock is now on a 5 per cent dividend basis. The directors meet next month on the next declaration.

The cash balance of the company is nearly $7,000,000. It is expected that by the end of the year the company will have practically wiped out its note issue amounting to $12,000,000.

Security Prices Higher

—

Sturdy Demand in All Stocks —Miller Rubber Makes High Mark

NEW YORK CITY, Oct. 18—A few substantial gains occurred last week in the securities markets, ranging from ½ to 30 points while the losses recorded ranged from 1½ to 15 points. There were many issues which recorded no change at all and these remained firm throughout the week. The trading conditions were somewhat brisker, although the buying was normal. A number of gains took place in the specialties. Chevrolet, which was first rated last week, made a gain of 26 points, the highest to take place in the specialties. Then following closely were Chalmers and Studebaker, both making their total gain 19 points. White made a gain of 16 points while the rest of the issues made either small or no gains at all.

Tire Prices Normal

Tire prices were normal last week, although many issues made but small gains. Miller Rubber made a gain of 30 points, the highest that has been recorded in the rubber markets for several months. Kelly-Springfield common and Firestone were weak in the early dealings and sold down sharply from the recent high level both had made. Swinehart and U. S. Rubber rose 2 points. Sales of stocks were small, as the buyers preferred holding back for further gains.

Detroit Stocks Active

Although the gains that took place in the Detroit market were not heavy the trading conditions were on a somewhat brisker scale. Here many stocks changed hands. Studebaker featured the market with a 16-point rise. Packard rose 5 points and Maxwell 3¼ points. The rest of the gains were small, ranging from ½ to 2¾ points. General Motors declined 25 points, being the only issue in Detroit to make a decline. The inactive stocks were weak, Canadian Ford declining 50 points.

—

U-S-L Convention Closes

NIAGARA FALLS, N. Y., Oct. 16—The annual sales convention of the U. S. Light and Heat Corp. was brought to a close to-night, more than 50 branch managers and salesmen from all over the country having been guests of the company for the past three days.

—

Form $100,000 Armored Car Co.

PHILADELPHIA, PA., Oct. 16—Joseph F. Curtain, Samuel B. Howard and H. O. Coughlan of New York, are the incorporators of the Armored Motorcar Co., capitalized at Dover at $100,000. The company will manufacture motorcars and aeroplanes.

—

Dividend Declared

Willys-Overland Co., quarterly of 1 1-2 per cent common; payable Nov. 1 to stockholders of record Oct. 21.

100,000 at St. Louis Car Show

25,000 of These Were Prospects and Dealers—Many Sales Reported

ST. LOUIS, MO., Oct. 14—The ninth annual automobile show of the St. Louis Automobile Manufacturers' & Dealers' Association came to an end on Oct. 9, the most successful in the history of the association.

Fully 100,000 persons saw at this show the first display of 1916 models west of the Mississippi River. Probably a fourth of that number were sub-dealers, farmers and other out-of-town prospects brought to the city by the Fall Festivities.

Tuesday, "Automobile Trade Day," was the most productive of sales. One of the biggest deals closed on this day was the sale by the Weber Implement & Auto Co. of a hearse and a squad of five sedans to an undertaker of Springfield, Ill. The new Chevrolet Co. of Missouri announced they had taken 272 orders for their Four-Ninety at the show. Several other distributors claimed they had obtained contracts for carload orders of their lines.

Joseph A. Schlecht, Allen, Jackson and Halladay distributor, treasurer of the Manufacturers' and Dealers' Association and chairman of the Show Committee—in short, commonly acknowledged as the "man who made the 1915 show"—said:

"We had a greater attendance than any year before. Sales were made every day by every dealer. Even the electric vehicle men sold more machines than at previous shows. The prime object of our association is to carry through the annual show. Though we do not aim to make money through admission fees, we no doubt did so at this year's show."

—

Fletcher Cup Run Oct. 31

PHILADELPHIA, PA., Oct. 16—The annual fixture of the Automobile Club of Philadelphia, namely the Fletcher Cup Run, will be held on Sunday, Oct. 31. The run, which is a continuation of the Brazier Cup Run, established by the club in 1902, is open only to members of the club, and owners or members of their immediate family must do the driving.

The Fletcher Cup Run is a test of the ability of a driver to keep his car at varying speeds designated on a chart given at the start, showing the route and speed required over each section of the course. Any contestant fined for speed will be counted out. The route, which will not be announced until the start, will cover about 60 miles, with a stop for luncheon. Speedometer dials will be covered and sealed, thus compelling the driver to estimate his speed. For every minute behind or ahead of the proper elapsed time in passing various unannounced controls, the car will be penalized one point, the car with the least penalization being the winner. The Fletcher Cup becomes the property of the driver winning it three times, not necessarily in succession.

—

Motor-Plowing Demonstration in Denmark

COPENHAGEN, DENMARK, Oct. 14—At the agricultural fair held at Vehle, Denmark, in July, a demonstration was given of three different motor plows—one manufactured in Denmark, one in Sweden, and one by the International Harvester Co. of America. These plows were of the smaller type, suitable for an average-sized farm. Two of the outfits were equipped with 16-hp. engines and one with a 12-hp. engine; their speeds ranged between 1 1-2 and 2 miles an hr. All were of the one-man type. When the necessary attachments are at hand the same tractors can be used for pulling binders. Two of them can be used for threshing purposes or other belt work without any change, while in order to do this with the Danish tractor an extended shaft with pulley is required.

At present there are in this country quite a few larger plowing outfits at work, and while these smaller outfits seemed to arouse considerable interest among the owners of averaged-sized farms, it is yet to be seen to what extent they can be sold.

—

Jackson Trailers in Three Types

JACKSON, MICH., Oct. 12—The Jackson automobile trailer is the latest product of the Miles Mfg. Co. of this city. The trailers are made for use by any kind of automobile. There are three different types, each with several models.

Where delivery body is ordered 1⅛ in. rubber tires are furnished while on trailers with rack style body, models 31 and 33, 1⅜ in. tires are fitted. On model 41, 1¾ in. rubber tires are used. All models have a universal joint coupling. The standard color is Brewster green. The prices range from $22 to $98, f.o.b. Jackson.

—

Automatic Traffic Signals for New York

NEW YORK CITY, Oct. 18—Automatic street signals for the control of traffic were in operation to-day at nearly all street corners where traffic policemen are stationed. The signals are a white standard with four arms, two of them red with the command Stop in white letters and two of them green with the order Go.

They are operated by the policeman on the corner who turns a handle which swings the signal and the letters are large enough to be read distinctly at a distance of 200 ft. The signals project over the street at a height to be read by all drivers.

—

New Motor Bus Line in New York City

NEW YORK CITY, Oct. 15—The Board of Estimate, after three years of study, has recommended that a franchise be granted to the New York Motorbus Co., to operate double deck, side entrance cars over 31 miles of Manhattan streets, from Union Square on the south to Fort George on the north. The company offers a 10-cent fare for main lines, a 5-cent fare for crosstown and other short lines, and transfers which will keep the cost of a continuous trip within the 10-cent limit.

Howard Conklin, 1 Wall Street, is president of the company. Other directors are S. M. Conklin and H. B. Weaver, the company's consulting engineer. The company agrees to have 100 buses running within eight months.

—

Armored Car Train for New York

NEW YORK CITY, Oct. 19—Governor Whitman of New York stated to-day that the State of New York soon will have an armored motor train. "This will be for service with the National Guard of the State," says Governor Whitman. "Certain public spirited citizens have interested themselves in the project by which the equipment is to be made available without cost to the State."

Other Governors, who already have interested themselves in the Automobile Reserve Corps are: P. L. Goldsborough of Maryland; E. L. Philipp of Wisconsin; George W. Hays of Arkansas; John B. Kendrick of Wyoming; Emmet D. Boyle of Nevada, and the Adjutant General writing for the Governor of Georgia.

—

Arthur Klein Opens Garage

YOUNGSTOWN, OHIO, Oct. 14—Arthur Klein, the automobile driver, has given up racing and has opened a garage and service station in this city. The new concern is known as the Kleinart Motor Service Co., 637 Elm Street. Frank Lightner, who rode as a mechanician with Klein in a number of races, is associated with him in his new venture.

—

Automobile Reserve for Maryland

BALTIMORE, MD., Oct. 16—Plans for the organization of a reserve automobile corps to serve as a branch of the Maryland National Guard are under way. The matter is being handled by Henry L. Rose, president of the Baltimore Automobile Club.

Factory Miscellany

Hess-Bright Adds—The Hess-Bright Manufacturing Co., Philadelphia, Pa., maker of ball bearings, has awarded the contract for the erection of a one-story 40 by 60 ft. addition to the hardening room at Front Street and Erie Avenue, at a cost of $3,980.

To Make Tires—The Hawkeye Tire Co., with a capital stock of $500,000, is being organized to manufacture a full line of standard size tires at a factory in Des Moines. Among the directors are E. G. Raffensperger, manager of the Des Moines Buick Co., and C. B. Hextell, a Des Moines attorney.

To Make Automobiles in Fort Madison—A new automobile company, to manufacture Champion cars, has acquired 7 acres of ground as a site for a factory at Fort Madison, Iowa. Bids for a two-story building, 100 by 200, the first factory unit, have been asked. Officers of the new company are identified also with the Perfection Tire & Rubber Co.

To Make Parts—S. W. Sorensen, formerly president and general manager of the Trio Mfg. Co., and J. B. Allen of the Olds Motor Co., have purchased the Brady-Nagel Mfg. Co. and will operate the same under the name of the S. A. Machine Co. They will manufacture automobile parts and specialties. The plant is equipped and is located at 518-520 Woodbridge Street, East.

Receives Drop Forging Order from Ford—The D. Wilcox Mfg. Co., Carlisle, Pa., has received a large order from the Ford Motor Car Co., for 580,000 pieces of drop forgings. The order amounts to many thousand of dollars and will keep the plant busy for the next 3 months at least. Additional men will be put on and other plans for an expansion are now in progress.

Nearly 31,000 Ford Employees—At the present time between 21,600 and 21,800 men are on the pay roll of the Detroit, Mich., plant of the Ford Motor Co. Of this number about 700 are employed exclusively in the general offices. At the assembling plants and service stations throughout the country there are now 9145 men employed, bringing the total force of Ford workers up to nearly 31,000.

Hartford Tire Pump Busy—The Hartford Tire Pump Co., Hartford, Wis., organized a year ago to manufacture compressors for application to motors, will immediately erect a new shop, which will also contain a complete garage and repair shop. The present quarters are in the Gehl Mfg. Co.'s works. The company is swamped with orders and intends to hasten construction work so that occupancy may be taken before midwinter. A complete welding and cutting apparatus will be installed in addition to considerable new power and manual tool equipment.

New Castle Tire Plant Busy—Much progress has been made by the New Castle Rubber Co. during the past several weeks since starting operations in the company's plant at Mahoningtown, just outside of New Castle, Pa. The plant is now running at nearly its full capacity. Additional men are being put on continually, and the orders booked will keep it running in full for some time. About 400 men are employed in the plant. The average output is between 250 and 300 tires daily.

Breeze Carbureter Adds—Work has been started on a two-story addition to the Breeze Carbureter Co. plant at 250-252 South Street, Newark, N. J. At present the manufacture of tubing by this concern is done in a one-story brick building having a frontage of 33 ft. on South Street, a depth of 120 ft. and a breadth which widens at the rear to 86 ft. In the rear of the present structure the reinforced concrete addition is being erected. The new quarters will give the plant 13,000 more sq. ft., making a total working space of 25,000 sq. ft. The addition will measure 80 by 80 ft.

Waukesha Motor Increasing Speed—The Waukesha Motor Co., Waukesha, Wis., manufacturing motors for passenger cars and trucks, is carrying out a new construction program which will afford much increased space for machine shop work in the present buildings and a new testing room and heat-treating department. Additions now under way include a new power and heating plant, 44 by 66 ft., and a new shop, 88 by 220 ft., for assembling and finished stock.

The Week in the Industry

Sheldon Hood Tire Mgr.—B. K. Sheldon has assumed the active management of the Quality Tire Co., 825 Main Street, Buffalo distributer for the Hood tire.

Logie Heads Toronto Chalmers—The Chalmers Motor Co. has opened a Canadian office at 18 Bloor Street, East, Toronto, with L. Logie as Canadian manager.

Manley Resigns—L. E. Manley has resigned as sales manager of the Adams-Oakland Co., Pittsburgh, Pa., and has assumed the duties of sales manager of the Wood-Oakland Sales Co., Cincinnati.

Marshall Buffalo McGraw Mgr.—G. J. Marshall has been appointed manager of the Buffalo, N. Y., office of the McGraw Tire & Rubber Co., East Palestine, Ohio. C. H. Connolly, former manager, goes to the Kansas City office.

Lindeman Firestone Western Ad Mgr.—C. B. Lindeman of the sales staff of the Seattle branch of the Firestone Tire & Rubber Co., has been elevated to the position of Western advertising manager. His headquarters will be in San Francisco.

—

Dealer

New Boston Company—W. J. Stusick and E. L. Warner have formed the Winchester Motor Co. at Springfield, Mass., and they have taken the agencies for the Moline Knight and the Vixen with salesrooms and service station at 776½ State Street.

New Toledo Tire Co.—The Ohio Tire Service Co. is the name of a new concern which has been incorporated, and is located at 310 Ontario Street, Toledo. Joseph Love is president and Samuel Love is general manager. The concern is distributor for Ohio tires.

Spokane Buick to Move—The Northwest Buick Co. of Seattle and Spokane, has contracted for a new building in the heart of the automobile district in Spokane. The building will give a total of 11,600 sq. ft. of floorspace. The building will be in First Avenue, near Adams Street.

Five New Studebaker Branches—Five new Studebaker branch houses are now either being built or are about to be. Under construction at present are three new Studebaker branches, at Brooklyn, Long Island City and Kansas City. Building operations on two more are about to begin, at Dallas, Tex., and Portland, Ore.

Motor Men in New Roles

Merritt Now Sales Mgr.—S. W. Merritt, formerly with the Moreland Motor Truck Co., Los Angeles, in the capacity of factory superintendent of production, is now with Hughson & Merton as sales manager for the farm tractor department.

Krimmel G. & J. Tire Sales Mgr.—Andrew Krimmel, formerly assistant manager of the Republic Rubber Co.'s Philadelphia, Pa., branch, has been appointed sales manager of the Berrodin Rubber Co., 715 North Broad Street, distributor of G. & J. tires.

Blackley Promoted—B. C. Blackley, for some time manager of the truck department of the J. C. Tucker Co. that handled the Chase and Vim trucks in Rhode Island, has been made New England division manager for the Chase Motor Truck Co. of Syracuse, N. Y.

Barber Eastern Branch Mgr.—Z. C. Barber, who was wholesale manager of the Saxon Motor Co. in New York City, has been appointed eastern branch manager of the Detroit Weatherproof Body Co., and will open a salesroom in New York City. His present offices are 2202 Broadway.

Minto Gibney Pacific Coast Mgr.—The Gibney Tire and Rubber Co., Conshohocken, Pa., has appointed C. H. Minto as Pacific Coast manager for Gibney Tires, with headquarters at San Francisco. He will have complete charge of the far Western business. His headquarters will be a factory branch.

West Returns to Portland—Fred West, who for two years, 1913-14, was at the head of the J. W. Leavvitt Co., Portland, Ore., has returned to that field in charge of the Chevrolet line. Mr. West will have charge of all of the territory of Oregon, Washington and Idaho with the exception of the city of Seattle.

Day Heads Buffalo Packard—Promotions in the organization of the Packard Motor Car Co. of New York are announced by the company as follows: B. C. Day of the New York city headquarters has been appointed branch manager at Buffalo; T. P. Myers, also of the local headquarters, has been chosen manager of the truck sales department.

Pittsburgh Franklin Reorganized—Reorganization of the distributing agency of the Franklin company has been effected and the company known as the Franklin Motor Car Co. of Pittsburgh becomes the Franklin-Pittsburgh Automobile Co. The officers chosen for the new company are W. M. Carr, president; R. S. Suydam, treasurer, and A. R. Gribben, secretary and assistant treasurer.

Hyde Opens Indianapolis Office—Harlow Hyde, formerly advertising manager of the Empire Automobile Co., has opened an office in the Telephone Building, Indianapolis, Ind., and established an advertising and publicity bureau. Mr. Hyde has been identified with the advertising and selling end of the automobile trade for many years, at one time having been advertising manager of the Bosch Magneto Co.

Mitchell Now Enger Dealer—R. D. Mitchell, formerly selling representative for Gray & Davis products and later for Kelly-Springfield and Pennsylvania tires, has organized the Enger Motor Sales Co., of Wisconsin, to handle the State territory for the Enger Motor Car Co., Cincinnati, Ohio. E. A. Glab, also well known in the industry, is associated with Mr. Mitchell. Headquarters are being established in Milwaukee.

—

Dealer

Newark Chalmers Moves—The service station and parts department of the Paddock-Zusi Motor Car Co., Newark, N. J., Chalmers dealer, has been moved to the company's new building at 894-896 Broad Street.

Hartford Co. Gives Free Service—The Auto Tire Co., 129 Allyn Street, Hartford, Conn., which does business also under the name of Jack The Tire Man, is exploiting its free service to tire customers. In order that the service may be broadened in scope a special service car has been commissioned. The plan now is to assist customers of the firm in tire trouble any distance from the store. The car will be on duty all the time.

Mason-Newark Velie Agent to Move—J. W. Mason, Velie and Briscoe agent in Newark, N. J., and at present located at 350 Halsey Street, will occupy a new building at 1005 Broad Street. The new building will be of the modern type of automobile sales and service station and will have a Broad Street frontage of 33 ft. and a depth on Kinney Street of 189 ft. The showroom, opening on Broad Street, will be 55 by 33 ft., finished in white tile with a mezzanine balcony. The second floor will be devoted to service.

Baltimore Trade Happenings—The Motor Car Accessory Co. has opened at 1201 North Charles Street, Baltimore. H. C. Clark and Frank Hoddinott are at the head of the firm. A general line of accessories, lubricating oils, etc., are being handled. The company also is distributor of the Newcastle tire.

A direct factory branch of the Firestone Tire & Rubber Co., Akron, will be opened in Baltimore next week. Temporary quarters will be established at 17 and 19 East Mount Royal Avenue, in a new addition which has been constructed to the quarters of the Zell Motor Car Co. building.

B. R. Leisure, who has been the manager of the Firestone branch at Salt Lake City is in Baltimore and will have charge of the local branch. His territory will include all of Maryland and large parts of Virginia and North Carolina.

Branches of the American Oil Co. of Baltimore are to be established in many Maryland towns. The American company, which refines and distributes Eze-Lube lubricating oil and which is one of the largest gasoline distributors in this section of the country, has established a branch at Cumberland, Md.

Recent Philadelphia Changes—About Jan. 1, 1916, the Republic Tire Co. will occupy a new four-story building now in course of construction at 806 North Broad Street, Philadelphia.

The Swinehart Tire and Rubber Co., at 320 North Broad Street, Philadelphia, will on Nov. 1 open its new and larger quarters at Broad Street and Fairmount Avenue.

Columbus Buick Adds—Oscar Lear, central Ohio agent for the Buick is making a number of changes at his salesrooms and garage at 286 East Long Street, Columbus. A 4800 sq. ft. service station has been built in the rear and a show-room has been added to the front.

Old Stutz Agency Bankrupt—The Stutz Motor Car Co. of Boston, Mass., that handled the Stutz until a month ago, has gone into bankruptcy with liabilities of $27,342.19 and $2,248.20 assets. The chief creditors are Edward M. Becker, $6,500, A. E. Chase, $6,500, and J. S. Bradstreet, $8,000, all of whom were identified with the company. There are about fifty unsecured creditors.

No More Gasoline Stands—Mayor James M. Curley of Boston, Mass., has just sent an order to the Street and the Park and Recreation Commissions of his city not to grant any more permits for sidewalk gasoline stands. He says in his letter that no such stands should be granted without a fee, and that as they are an obstruction to traffic care should be taken not to allow any more to be put up. Furthermore fees should be charged for those now in use as a rental at so much per year.

New Sparton Horn House Organ—Everybody's Business is the title of the new house organ of the Sparks-Withington Co., Jackson, Mich., manufacturer of the Sparton safety signals. The magazine is a monthly publication devoted to the better acquaintanceship between employees and employer. It will contain articles of every kind which will be both educational and humorous. William Sparks is the managing editor and G. C. Core the news editor.

Late Missouri Trade Items—The Fisk Rubber Co., St. Louis, Mo., has leased the southeast corner of Grand Avenue and University Street where it will improve the present building preparatory to increasing its stock of tires.

The Pierce Oil Corp. has virtually closed a deal for a large lot at the corner of Fourth and Monroe Streets, Hannibal, where it will erect a warehouse, tanks and filling station. This depot will act as distributing point for northeastern Missouri and probably the west central part of Illinois.

Bert A. Stephens, F. B. Stephens and A. B. Gauge have opened an automobile supply house at 432 St. Louis Street, Springfield. They will deal chiefly in tires.

The Kansas City Motor Sales Co., Kansas City, has been incorporated and has established office and salesrooms at 1711 Grand Avenue. The chief business of this company will be to sell Ford cars on deferred payments, and to make exchange of Ford cars in Kansas City and territory.

The Ford Automobile Co., Kansas City, which is doubling the size of its branch plant at Eleventh Street and Manchester Avenue in this city, will have the extension completed and ready for occupancy by Dec. 1.

Boston Co.'s in New Quarters—The Reo Motor Car Co., The Hupmobile Co. of New England and the Joseph S. Porter Co., agents for the Pathfinder and Regal cars, have all moved into the new building near the junction of Commonwealth Avenue and Beacon Street, adjoining the Marmon at Boston, Mass. The structure is divided into three sections, the Reo on the east, Pathfinder and Regal in the centre and Hupmobile on the west. Both the wholesale branch of the Hupmobile and the new retail agency will occupy the western section.

Willard's New Coast Quarters—The Willard Storage Battery Co. has opened quarters at 1433 Bush Street, San Francisco. Fourteen new service stations have been added by the company. This brings the total of Willard stations to 535. The most recent additions are: Conklin & Spindler, Chicago Heights, Ill.; Wells Garage, Wells, Minn.; Weber Battery Co., 1312 W. Jackson Blvd., Chicago, Ill.; Handy-Lewis Motor Car Co., Willmar, Minn.; Hackler Battery Co., Kaufman and Twenty-second Streets, Paris, Tex.; G. G. Gardner, Estherville, Neb.; Thorne Electric Co., 515-16 Center Avenue, Bay City, Mich.; C. E. Coogins, El Centro, Cal.; Woodward Tire & Repair Co., 1325-27 Woodward Avenue, Detroit, Mich.; C. P. Seeberg, 1918 Tuoulumne Street, Fresno, Cal.; Geo. H. Gant Electric Co., 320 S. Boots Street, Marion, Ind.; Herbert Hedges, Oxnard, Cal.; Slayton Power Co., Slayton, Minn., and Electric Garage Co., Third and Main Streets, Woodland, Cal.

Gemmer Co. to Build—Plans have been prepared for the construction of a two-story 40 by 60-ft. plant at Detroit, Mich., for the Gemmer Mfg. Co., manufacturer of automobile parts.

Rotary Motor Co. to Build—The Rotary Valveless Motor Co., Auburn, Wash., recently incorporated with $100,000 capital, by J. O. Menard and others, will build a factory for the manufacture of its specialty.

Recent Incorporations in the Automobile Field

Delaware

WILMINGTON—Standard Accessories Co.; $100,000; maker. Cloyd Marshall, 81 New Street, New York City.

District of Columbia

WASHINGTON—Livingston & Co.; $5,000. Leroy Livingston, J. L. Smith, W. N. Wood.

Illinois

CHICAGO—Good Care Garage Co.; $5,000. J. J. Purcell, J. Gumburger, E. S. Purcell.

CHICAGO—Sporub Tire Co.; $2,500. Jacob Levin, Davis Blumrosch, Lazarus Krinsky.

VANDALIA—Midland Accessories Manufacturing Co.; $150,000.

Indiana

AUBURN—Union Automobile Co.; $100,000. C. M. Brown, John Zimmerman, W. H. Schaab.

FRANKLIN—Continental Auto Parts Co.; $15,000; maker. J. H., S. C. and M. N. Staley.

LAPORTE—Indiana Mutual Automobile Insurance Co.; to do a mutual insurance business. F. C. Brewer, F. H. Henderson, F. J. Cook.

Kentucky

LEXINGTON—Taxicab Co.; $7,500. B. J. Mathews, Frest Hall, Annie Kendall, B. D. Berry.

Maryland

EMMITTSBURG—Emmittsburg Motor Car Co.; $10,000. E. E. Zimmerman, J. W. Wagerman, E. F. Ohler, D. F. Roddy.

Michigan

DETROIT—General Manufacturing Co.; $5,000; to manufacture and deal in automobile accessories, machinery, etc. C. W. Olson, C. R. Robertson, Henry Wild.

DETROIT—National Bronze & Aluminum Castings Co.; $10,000. P. J. Donnelly, V. R. Donnelly, R. L. Pratt.

FLINT—Monroe Motor Co.; $250,000 to $735,000.

MOUNT PLEASANT—Mount Pleasant Motor Co.; $5,000 to $15,000.

North Carolina

AYDEN—East-Over Corp.; $10,000; automobile dealer. J. R. Turnage, B. S. Sumerel.

North Dakota

HARVEY—Blanding Motor Co.; $10,000. C. H. Blanding, Adelaide A. Blanding, Millie L. Blanding.

New Jersey

MONTCLAIR—Brooks-Ostruk Co.; $5,000. Paul Ostruk, William H. Booth, Emerson Brooks.

New York

BUFFALO—Knoll Automobile Electric Service Co.; $5,000; electric equipment, automobiles. C. A. Hamlin, F. J. Rogan, J. G. W. Knoll.

New York City

Metropolitan Motor-Vim Agency; $50,000. W. C. Freeman, B. B. Stowe, C. Plock.
Utility Motor Trucking Co.; $200,000. J. M. Greene, E. M. Klein, Jennie Alex.

Ohio

CANAL DOVER—Dover Buick Co.; $5,000. H. C. Campbell, H. E. Haas, O. H. Weaver, E. G. Weaver, R. J. Weaver.
CLEVELAND—Auto Casting Co.; $10,000. W. R. Wildman.
CLEVELAND—Electric & Auto Parts Co.; $50,000. J. H. Ladwig, R. R. Bachelier, F. E. Lazare, G. W. Cowley, E. W. Slater.
CLEVELAND—Fred P. Brand Motor Co.; $30,000. F. P. Brand.
CLEVELAND—Cole-Cleveland Co.; $10,000. C. D. Simmons.
CLEVELAND—K-K Co.; $15,000; automobile dealer. F. W. Emslie.
CLEVELAND—The Keystone Oil & Supply Co.; $10,000. R. H. Lee, W. J. Patterson, G. M. Gallagher, E. M. Holmgren, S. D. Corbett.
CLEVELAND—The Motor Equipment Co.; $10,000; accessories. O. D. Summers, H. K. Summers, W. H. Everhart, M. Manshower, J. B. Moore.
CLEVELAND—The Ohio Electric Sales Co.; $10,000. O. K. Herron, W. A. Albaugh, Luther Day, R. E. Bixby, J. B. Kanner.
COLUMBUS—Shilling Safety Auto Bumper Co.; $100,000. F. W. Schriner, E. C. Shilling, Jacob Dagger, R. N. Ulrey, J. C. Erwin.
COLUMBUS—The Peters Sales Co.; $10,000; selling the Brinnon Ford starter. C. M. Peters, Albert Peake, G. A. Peters, J. B. McGaughy.
LLANO—Llano Motor Co.; $50,000; engine maker. M. D. Slator, M. M. Moss, E. G. Bogusch.

Pennsylvania

ERIE—Erie Trailer Mfg. Co.; $100,000; to make trailers for automobiles and trucks. H. A. Wilburn, C. C. Leon, F. J. Behrens.
UNIONTOWN—Gallatin Automobile Supply & Repair Co.; $5,000. W. H. Helmey, J. T. Hoover, C. H. Helmey, George Patterson.

South Carolina

COLUMBIA—New Zion Motor Co.; $3,000. W. C. Plowden, D. C. Shaw.
SUMMERTON—Summerton Motor Co.; $3,000. D. C. Shawk, H. A. Richbough.

Texas

CROSBYTON—Texas Auto Co.; $1,000. A. J. McKinnon, G. M. McGee, C. W. Murray.
WACO—Court House Garage and Supply Co.; $5,000. J. J. Richards, John McGlasson, J. E. Watson.

Virginia

ASHLAND—Hanover Garage and Repair Co.; $10,000. Boxley Vaughan, F. W. Tucker.
CLIFTON FORGE—Virginia Garage Co.; $30,000. B. H. Tatum, E. A. Snead, B. C. Goodman.

Washington

SPOKANE—Chalmers Auto Co.; $10,000. M. McInnis, O. E. Logan.
WALLA WALLA—Franklin Motor Co.; $75,000. B. H. Tuttle, Alex McKenzie, Inez Tuttle, Vivien Cookerly.

West Virginia

MORGANTOWN—Morgantown Jitney Co.; $3,000. F. M. Lucas, R. M. Davis, Fannie Davis, Hazel Lucas, Mabel Wilson.
WHEELING—Auto Accessories Co.; $5,000. P. F. Haberstick.

Wisconsin

LA CROSSE—Zimmer Motor Car Co.; $5,000. J. E. Zimmer, O. H. Matzke, Susan Zimmer.

Virginia

ROANOKE—Meadow-Price Co.; $1,000 to $50,000. D. S. Meadows, R. E. Price.

The AUTOMOBILE

The History of the American Automobile Industry

Opening Chapter of History of America's Great Industry—First Time the Complete Story of Early Endeavors Has Been Told—To Be Published Serially and Later in Book Form

This Issue—The Scope and Early Efforts

By David Beecroft

THE practical and continuous development of the gasoline-engined automobile in America dates back to 1891; the first application of an electric motor coupled with a battery to propel a vehicle dates to approximately 1884, marking the advent of the pioneer, but the practical start of the electric vehicle industry dates from 1893 or 1894; and the pioneer in building steam road automobiles or locomotives as they were then called goes back to 1769, when the movement had its inception, although steam automobiles, as we now know them, date back little further than 1887, when our pioneers brought out their initial machines for passenger use.

Idea Is Centuries Old

The concept of building a vehicle that would run without horses is centuries old: Visions of the motor vehicle are recorded in Holy Writ, our ancient historians record prophecies by the great scientists; and poets wrote centuries ago of the possibilities of the fleet motor vehicle that would navigate the seas, traverse the land and cleave the air. While the practical development of the automobile in America covers a span of thirty-five brief years, yet the brains of earlier days handed to our inventors and pioneers of the present generation the essentials of the automobile as we know it to-day. Hence to get the broad perspective of the history of the automobile in America it is necessary to review the recorded efforts of the last 50 years both in America and Europe, for in them we find the roots of the many constructions constituting the warp and woof of the present-day car.

First Internal Combustion Engine

In 1791 Barber's internal combustion engine marked the first recorded effort from which the gasoline engine of to-day is the offspring. The thread of progress was slow and it was not until 1876, when for the first time the charge of gasoline vapor was compressed that the possibility of the high-compression engine of to-day was a reality. It was 10 years later before Daimler and Benz in Germany gave us their engines, and in 1892 before Charles E. Duryea and his brother Frank gave us our first practical American gasoline automobile.

Pneumatic tires were made and used in 1845; the differential gear as used in the rear axle dates to 1828, when a Frenchman, Pecqueur, used it; the pivoted axle ends carrying the front road wheels were used in 1818, nearly a century ago; we have had the irreversible steering gear since patented by Jentaud, a Frenchman, in 1878; the use of the hot tube for igniting an explosive mixture takes us back to 1791; the use of the electric spark in ignition was recorded in 1853; and the use of springs, wheels, frames and other essentials carries the

reader far back into other centuries of the past.

To trace the growth of the automobile, as suggested by these conspicuous landmarks, it is imperative to turn back the pages of a century or more and analyze the outside influences that were factors in stimulating the industry or retarding it. War, always a retarder, exerted its influence a century ago, hostile road laws held the movement back in certain countries and the lack of improved roads exerted a strong retarding influence.

A Tremendous Subject

Yet, no apology is needed for a history of the great and still rapidly growing American automobile industry, but having delved into the earlier facts connected with the industry further than has heretofore been attempted in America, we recognize better than our readers possibly can how much limited space and time have compelled us to leave undone and although giving a great amount of information that is new to them and to the world at large, we regret that the limitations mentioned do not permit us to make it larger.

While it is well known that histories in general recite only the main parts and leave unmentioned the less important ones, it is not so well recognized in a history of this kind, that it is the exceptional which received mention, while the more common or commonplace, even though equally good, is neglected. The thought that, "Full many a flower is born to blush unseen and waste its sweetness on the desert air," has been constantly exemplified in connection with the automobile industry.

Foreign Influence

While it has been our intent to confine ourselves to the history of the industry in America we have been forced to constantly refer to work done by foreigners for several reasons. The ancient history is as much our inheritance as that of any other people and we give in these pages the more important points therein that our readers may understand the age and growth of this history-long problem and its bearing on our modern productions. The publications of foreign countries reach America much more freely than American publications go abroad because of the fact that many of our people or their immediate ancestors were foreign born and therefore take interest in things happening abroad. Our most liberal patent system is taken advantage of by foreign inventors quite freely and on these accounts foreign influence and foreign work have very materially affected American development and cannot therefore be ignored in an unbiased American history.

Several other factors have influenced the industry in America that were not felt or were felt to a much different degree in Europe. Probably the most important of these is the road problem. In this new land there are almost no roads whatever in the sense that the improved highways of Europe exist. At the beginning of the modern automobile movement there were practically no improved roads in this country. The rise of the automobile and modern road building in America have been exactly contemporaneous. In 1891 New Jersey passed the first road improvement bill and the first American automobile was begun by C. E. Duryea. Straggling road improvement and likewise straggling growth in the automobile industry during the next seven or eight years, but a considerably increased activity both in roads and automobiles thereafter. The difficulties imposed upon our automobile inventors by our money wasting excuses for roads, has been a matter of comment by foreigners visiting us ever since we arose to the dignity of a nation.

A second very important factor has been the cost of horses and horse feed. In this land of broad area and fertile acres feed has been so cheap and horses so plentiful that the incentive to secure transportation other than by animal power and thus save hay and oats has not appealed to our inventive minds or our buying public as it has in the more thickly populated European lands where horses have been much more of a luxury. The very commonness of the horse made him the companion of all our people to such an extent that few believed he could be displaced in their hearts by a mere machine, no matter how swift or how economical it might prove to be. So certain were several of our automobile pioneers that no one able to afford a stable and hold the lines over a lively, intelligent and beautiful animal would ever purchase or drive for pleasure a machine vehicle that their earliest efforts were directed toward supplying transportation for those city brothers, who could not afford or whose surroundings would not permit maintaining a horse and stable. Such a view naturally did not encourage work toward a solution of the automobile problem. The limited market and the certainty that the price must be low and perhaps taken in installments made it necessary that the vehicle should be of the cheapest possible design and construction, and it was not until experience gained by riding on his brains showed that the motor vehicle opened a new world that Duryea and his brother Frank began in 1893 to develop the automobile for the high-priced market. It takes time to establish a manufacturing industry or create a manufacturing people, and naturally the newer country remained an agricultural one and looked to Europe for its mechanical supplies.

American Inventions

In spite of these and other reasons American inventors made a record to be proud of, and although not so numerous because our population was not so large and perhaps not so successful, for reasons above given, yet the records show that they were not laggards, but were closely in touch with the world's progress and often leading it; in fact, the record frequently shines with such brilliance that every patriotic American must glow with pride and should wonder if our national recognition and treatment of the American inventor is as liberal as his efforts and devotion to his work merit. The steamboat, the ironclad, the telegraph, telephone and electric light, the grain harvester, the submarine and aeroplane are familiar examples of

American ingenuity leading the world, and our pages will show a goodly number of such examples in the automobile business.

Solving the Problem

No mechanical problem, except possibly flying, remained unsolved so long as this one of self-propelled vehicles, and no problem has ever had expended upon it so large an amount of thought, effort and money in so many parts of the world or by so many people or under such widely divergent conditions. While it is true that many hinderances, particularly bad roads, and in some cases restrictive laws, hindered or stopped the work, it is safe to assert that no mechanical problem has proved so difficult of solution as this one and it has required not only a very high order of mechanical ability, but the growth of mechanical progress and the combination of ideas from many sources in order to accomplish it.

In writing the history of the automobile in America it is almost paradoxical that there is no first. Each man had been preceded by work which led up to his efforts and, which if he knew of them, undoubtedly assisted him materially. In passing judgment upon the work of the various people care must be exercised to note whether he was an originator or whether he was simply a sporadic worker, who did very little outside of his single effort and who added very little to the final result; or, whether he was persistent and kept his work going ahead until it did finally affect the entire industry.

Judged by these standards, we find that, although the automobile industry could have been developed many years earlier, using the material at hand and using no new devices whatever, it was not until certain persistent individuals came along who, having taken up the work and put their hands to the plow, continued until the industry became influenced by their work. Judged by this standard Charles E. Duryea, Ellwood Haynes and Alexander Winton were the pioneers in the gasoline vehicle work; Morrison & Salon were pioneers in the electric, and S. H. Roper, followed by George E. Whitney were the steam pioneers. R. E. Olds, Henry Ford, King and others followed close after as did Woods and the Stanley brothers.

Ancient Vehicles

The self-propelled carriage concept is undoubtedly almost as old as carriages of any form. The drag or sled which slid down a hill without assistance was not only the first self-propeller, but with no less doubt awoke within the mind of its possessor a desire to enjoy similar self-propulsion on the level and up hill just as every child coasting with his sled desires this thing. That our records of the automobile do not go back so far is not because the idea did not exist, but because it was not successfully carried out.

The oldest recorded vehicles are Egyptian war chariots whose pictures are sculptured on the enduring monuments dating back probably 2000 years B. C. The wheels of these chariots varied from 30 to 39 in. and thus corresponded very closely with modern automobile sizes.

The first written mention of vehicles is in the Bible, where Joseph sent wagons to assist in moving his relatives. By the time of Solomon, some 500 years later, chariots were so plentiful as to be mentioned in thousands, and it is at about this time that the first written mention of the automobile idea is found in Homer's Iliad, 18th Book. That it is not found sooner is more probably due to the fact that writing itself was new at the time of Moses and the alphabet very imperfect (16 consonants only) until about the age of Solomon and Homer.

The Art in Homer's Time

That the arts of carriage making were considerably advanced in Homer's time (1000 B. C.) or before, is conclusively shown by mention in the fifth book of the Iliad, where the advantage of using a different metal for the bearing than that used for the axle is clearly indicated in the assembling of Juno's chariot:

"by Hebe, ever young,
The whirling wheels are to the chariot hung.
On the bright axle turns the bidden wheel
Of sounding brass; the polished axle steel.
Eight brazen spokes in radiant order flame."

These wheels undoubtedly were cast in a single piece just as the one-piece steel wheels used on many heavy trucks to-day, and there is some indication in the text that they were even turned, or in some manner machined on their circumferences.

The following quotation shows plainly the existence of the conception of self-propelled vehicles in Homer's time. He describes Juno as seeking aid from Vulcan the lame blacksmith and—

"There the lame architect the goddess found,
Obscure in smoke, his forges flaming round,
While bathed in sweat from fire to fire he flew;
And puffing loud, the roaring bellows blew.
That day no common task his labor claimed;
Full twenty tripods for his hall he framed,
That placed on living wheels of massy gold,
(Wondrous to tell) instinct with spirit roll'd
From place to place, around the bless'd abodes
Self-moved, obedient to the beck of gods."

Iliad 18th Book.

From other sources also we learn of self-moving apparatus in use in the temples before the Christian era; the priests being leaders in mathematics and mechanics in those times. How these devices were moved is not known, although some very ingenious arrangements for other purposes have come down to us. It is practically certain that the first forms of vehicles that were not drawn were propelled by man-power often concealed for the mystification of the public or for protection from the enemy. The Ethiopics of Heliodorus mention a triumphal wagon as having been used at Athens, which was moved by men carried therein and similar references are found in other authors. The moving forts or shields used by armies were carried or pushed rather than propelled and can hardly be considered mechanical devices. Friar Bacon

wrote in the thirteenth century of mechanical possibilities and said, "it will be possible to construct chariots so that without animals they may be moved with incredible speed." Certainly the racing creations of to-day would amply satisfy this speed prediction.

Chinese Wind Wagons

Vehicles propelled by a rowing or pushing action and also by sails were seen in China by western travelers in the fifteenth and sixteenth centuries with no record as to their first use, which may have been centuries before. Sails are still used in China to assist in propelling their crude wheelbarrows or carts, but they are hardly independent of man power and therefore not proper examples of this art.

Beginning with about 1600 sailing carriages were made in Europe by the celebrated mathematician, Simon Stevin of Holland. One in particular carried five passengers and another had a capacity of twenty-eight passengers. This latter was simply a box on wheels with two masts and sails and with the rear axle arranged so that it might be steered. In short, a boat running on wheels instead of on water. A description of a trip made in the larger car recites a run of 42 miles along the Dutch coast in two hours with full passenger load. The smaller carriage was kept at Scheveningen as late as 1802, but had not been used since 1748.

The rope or chain steering cable wound around the steering column and much used on traction engines and more recently on cycle cars, dates back to a Holland wind wagon of 1740.

The Use of Kites

Many other accounts of wind-driven vehicles are to be found which carry this art down to the present day and include sail-driven vehicles on the prairies of the central United States as well as sail-driven bicycles and skate sailing, both popular sports in some localities.

One of the most interesting accounts of wind-driven vehicles is found in Pocock's "Navigation in the Air by the Use of Kites or Buoyant Sails, 1827," in which he describes many trips made about England and also fishing vessels driven by means of his controllable kites. By the use of three or four cords he was enabled to make his kites pull strongly or float lightly on the air at will and also to tack one side or the other just as sails are set at an angle to the wind which, coupled with a proper steering device, enabled his vehicle to be run almost into the teeth of the wind. Speeds of a mile in 3 min. were frequently attained and fishing smacks drawn by kites traveled much faster and were not becalmed so often as those dependent on sails.

The use of springs for carriage propulsion was suggested early and has persisted until the very end of the last century. The first known attempt was made in Paris by an Englishman in 1644. Patin tells us "this carriage was intended to run from Paris to Fontainebleau and back in a single day," and that it was thought there would be "a great economy in hay and oats." The device apparently worked well on a floor, but anyone knowing the amount of power required by a successful motor vehicle can readily understand that winding these springs by men would not be a practical method. Another attempt with a spring motor was made by Vegelius, a Jena professor, who in 1679 made a spring-propelled horse covered with the skin of a real horse, which on level ground was able to cover 4 miles in a day. How often it required winding or how long to wind is not stated.

Propulsion by Spring Power

The spring carriage problem again and again received attention with each wave of development of locomotives or railways and in the latter part of the last century several very serious attempts were made to propel street cars by the spring method. The almost level and practically perfect track permitted carrying a heavy load of springs while the possession of mechanical power for winding them removed one of their most objectionable features. Steel making had progressed by this time so that much better and much larger springs were quite possible to secure. Among these attempts may be mentioned a spring-driven omnibus tried in New Orleans in 1870, a street car tested in Philadelphia later, and another one tested between Richmond, Va., and Manchester in 1891. This car weighed about 1000 lb., carried ten people on a successful trial trip and employed eight springs, each formed of a strip of steel 8 ft. long by 18 in. wide by 3/32 in. thick, estimated each at 2 hp. or a total of 16 hp. Suitable mechanism permitted applying one or more springs at a time as the amount of power was needed.

Many Patents Sought

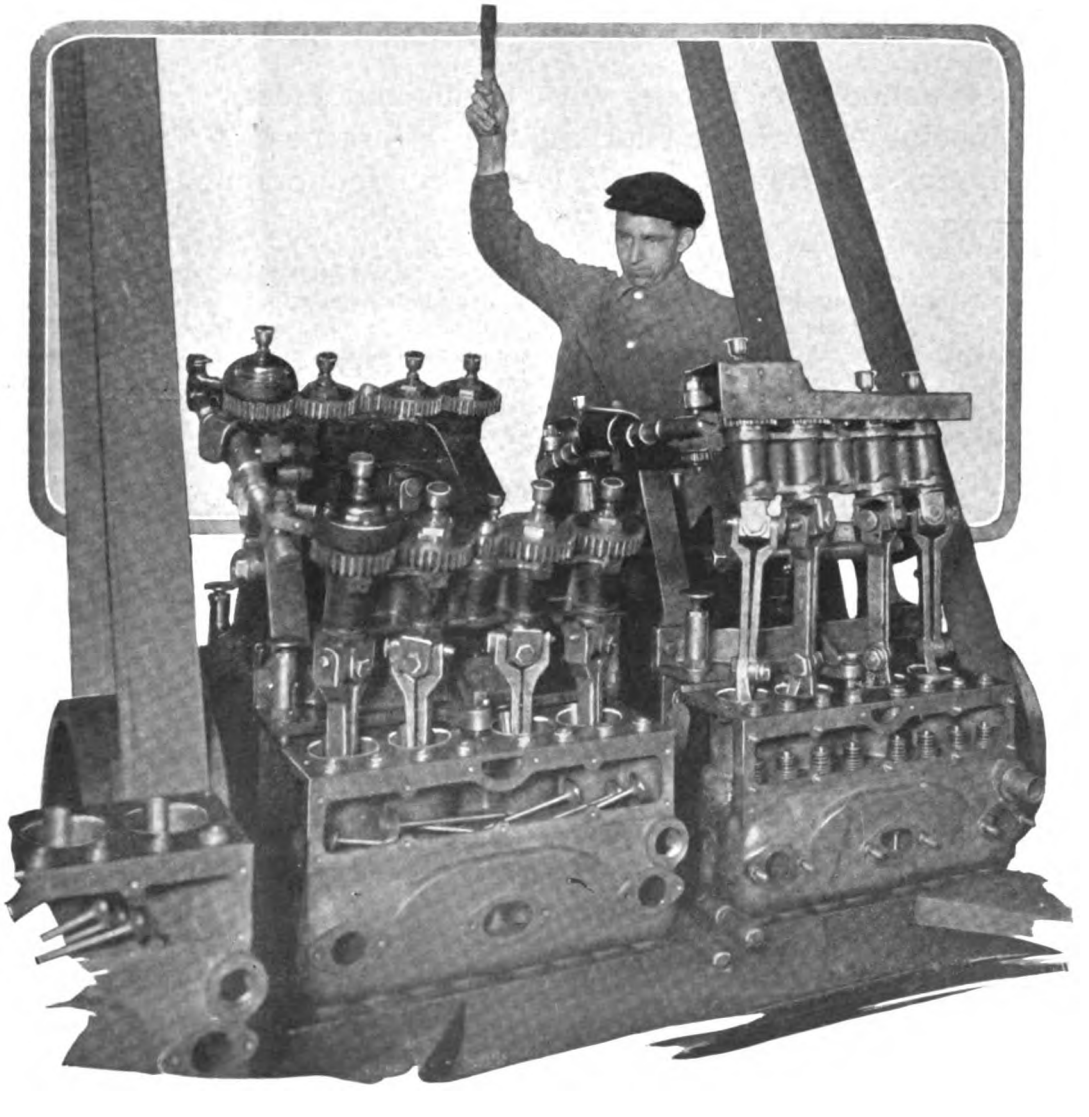
The latter part of the century embracing about thirty years, from 1866 to 1897, shows a very considerable activity in spring-propelled vehicle designs. This activity is coincident with great activity in other lines and a part of that larger movement of the national life toward a much wider manufacturing and distributing activity which began to develop after the Civil War. United States patent records show fully fifty different attempts before 1900, but they are of very little interest to the motor vehicle art because they were in no sense permanently successful nor did they add anything to the stock of knowledge or the mechanical devices needed to make the industry a success. On the contrary, they show evidence of being rather the efforts of those who were not well posted either as to the requirements or the history of the art and who, therefore, could hardly be expected to add anything to it.

While in general the self-propelled vehicle is designed to displace the horse, a part of the progress to this end has been the construction of vehicles propelled by horses employing treadmill or turntable mechanism. It was quite early recognized that, given good roads or a good track, animal muscle can be expended to better advantage than in the natural process of walking or running and that a horse may propel the vehicle and himself

farther and faster than he can pull it just as a cyclist can cover two or three times as many miles in a day in spite of the added weight of his machine than he could possibly do afoot. In 1824 Snowden, a British mechanic, proposed a two-story turntable or merry-go-round, on the lower floor of which the horses walked in a circle to propel the structure. He seems to have had the then very common notion that to get traction cogs were necessary, and his vertical driving shaft seems to have extended down into a slot in the road with a pinion on the lower end meshing into a rack in this slot. Stevenson, known for his locomotive, claims to have had designs for a treadmill device and one of these, Brandreth's cyclopede, was tried on the Liverpool and Manchester Railway in a competition held in 1829. It failed to attain speeds higher than 5 or 6 miles per hour.

Other experimenters frequently had this idea in mind, which is not to be wondered at when we remember that in the early part of the last century the treadmill operated by horses, oxen, dogs, convicts and slaves was not an uncommon method of securing needed power.

While the expansive force of gunpowder was early recognized as a possible source of power and was probably tried before any modern application of steam and has been tried many times since even as late as 1891, it is is to steam that we are obliged to look for the first really successful self-propelled carriage. The difficulties connected with building and operating gas and hot-air engines, or their predecessor, the gunpowder engine, were not sufficiently well understood when the early attempts were made to permit their being overcome, while the inability to get suitable machine work for such engines and suitable lubrication made them practically out of the question. It was not that the thinkers of those days were unaware of the principles involved or of the possibilities, but that they were ahead of the age and therefore ahead of the market as well as ahead of the practical equipment needed to do the work. Some idea of the imperfection of machine tools may be gathered from the fact that Watt wrote a friend about his steam engine and explained that he had succeeded in getting the piston fitted to the cylinder so accurately he could not insert anything thicker than a half crown between them. Only a mechanic who has worked under such discouraging conditions can appreciate the joy that the pioneer of steam would have felt had he been able to secure work down to fractions of a thousandth of an inch in accuracy, as is quite practical to-day.

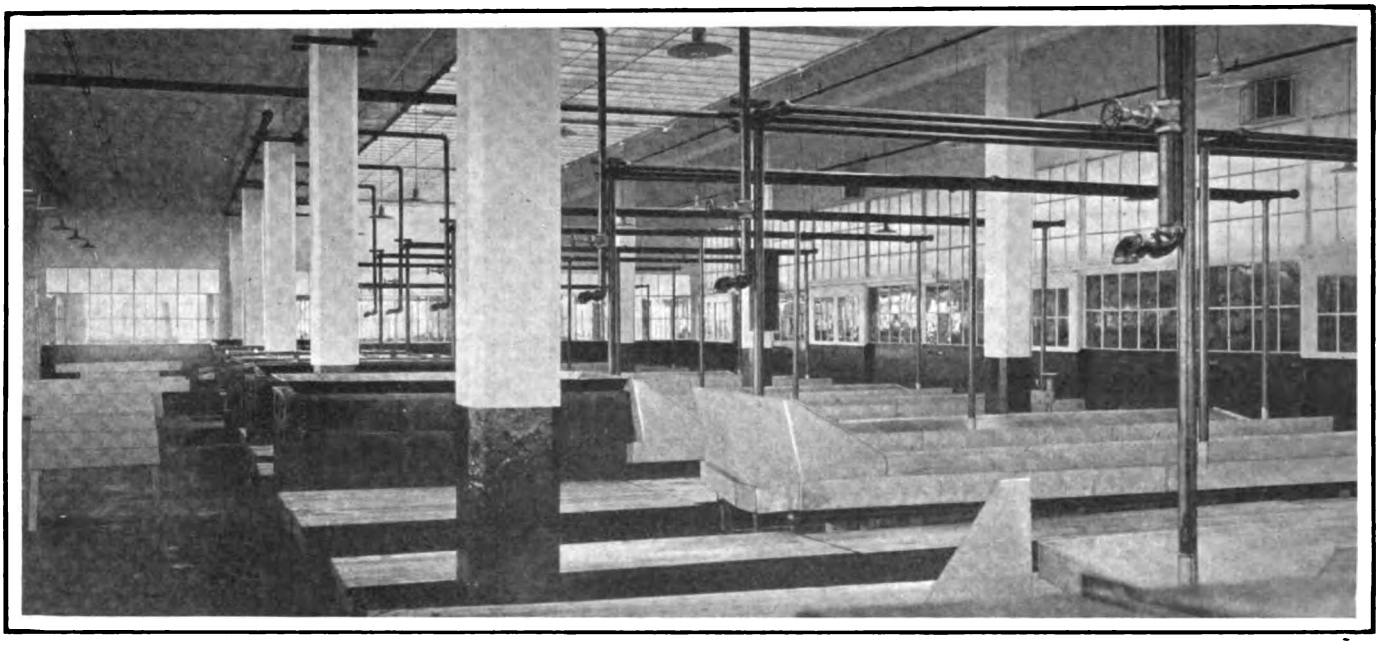


Piston Lapping Machine a Labor Saver for Hupmobile

The illustration shows a novel machine in the factory of the Hupp Motor Car Co., Detroit, Mich. It is called a piston lapper, and was designed by the concern. Four blocks of cylinders are placed on the machine at one time, two on either side. By a "walking beam" movement, the pistons attached to the machine are forced up and down in the newly machined cylinder blocks until a good lap fit is obtained.

At the same time as the up-and-down movement is being carried on, the pistons are made to revolve by gears at the top of the piston linkages. This is to insure a perfect lap fit.

By the use of this intricate-looking device, one man now does the work formerly done by eighteen men—an enormous saving of labor cost.



One of the two dipping rooms at the Buick plant where aprons, fenders, radiator shells, etc., are immersed in enamel by men in dust-absorbent clothes. The parts are then hung on racks to allow excess enamel to drip off. Hoods are dipped in a separate room at one end. Each of these rooms has a separate supply of washed air

Eliminating Dust in Body Enamelling

Buick Uses Washed Air, Rooms with Walls and Floors Oiled and Special Absorbent Clothing for Workmen—Spraying, Dipping and Baking Avoid Delay in Production

By L. V. Spencer

THE body painting and metal parts enamelling departments are the bugbear of many an automobile manufacturer. Fine finish is one of the things that helps to sell cars these days, yet it is a costly feature to obtain, and it takes time to produce it. Dust is its deadly enemy; it frowns seriously upon rapid production insofar as this branch of the work is concerned.

For there are probably no parts of the average plant that take up more room, are conducive of more waste and hold onto the car longer in its journey to completion than those divisions which have to do with these color processes. Though rapid production kinks are constantly being installed in other departments of the average plant, little thought is given to methods of speeding up the painting operations without in any way sacrificing the desirable fine finish. Methods which have been in vogue since the carriage days are still adhered to in most painting rooms, with the result that while production is speeded up at a great rate in all other departments, there is a marked slowing down again when the car reaches the "paint." Hand work is usually employed, with the time-honored paint brush monarch of all it surveys.

Paint Usually Slows Production

Several of the big makers, however, have been studying this matter of painting, and have realized that they could get the cars out faster with some modern methods of quickening the processes. The main operations in painting and enamelling are to apply the paints or varnishes and then to dry them. So the production men have studied the problem, and now in many plants where the output runs into thousands of cars a year, both of these operations have been hurried. Application of the colors is done in many cases by either dipping the parts into them or by spraying them, and drying is hastened by huge ovens.

New Methods for Parts

While this development in painting and enamelling does not apply to the bodies of cars to any great extent, many large producers employ the new methods in enamelling the metal parts. No doubt the spraying and baking scheme will be extensively extended to body finishing as time goes on, and facilities for uniformly and smoothly applying the coats in this way to such large and unwieldy surfaces are perfected.

Typical of the very latest in the new era of enamelling and painting plants is the building belonging to the Buick Motor Co., Flint, Mich., especially for the enamelling of metal parts and the spraying of varnish onto wheels. The utmost rapidity of applying the coats to the parts is made possible, and huge baking ovens do the work of quickly drying these coats. No loss of time is occasioned by the new department, the capacity of which is every bit as great as any other part of the big factory.

All chassis metal parts, such as fender irons, hoods, fenders, radiator shells, and the like receive lasting coats of enamel here, and the pains taken to assure a smooth and lustrous finish are almost unbelievable. Dust is recognized as the enemy of the whole process, and the means employed for

eliminating that microbe from the varnish and enamel surfaces is most elaborate.

Color Sprayed on Wheels

There are also some new ideas worked out in the coloring of the wheels by spraying, then baking them in ovens similar to the enamelling ovens. A surprising saving of time is the result of this wheel painting method, for it takes considerable time to properly coat each spoke with a hand brush.

The new Buick enamelling building is three stories high and measures 110 ft. wide by 260 ft. long, giving a total floor-space of 85,000 sq. ft. The arrangement of the floors is given in the floor plans herewith. Throughout, the new building has been laid out for a production of 350 cars a day. This does not mean that only 350 wheels can be colored in a day, but that enough for that many machines can be put through —1400 wheels. This applies to fenders and other parts as well. Each car has four fenders, so the fender capacity is 1400 per day, and so on.

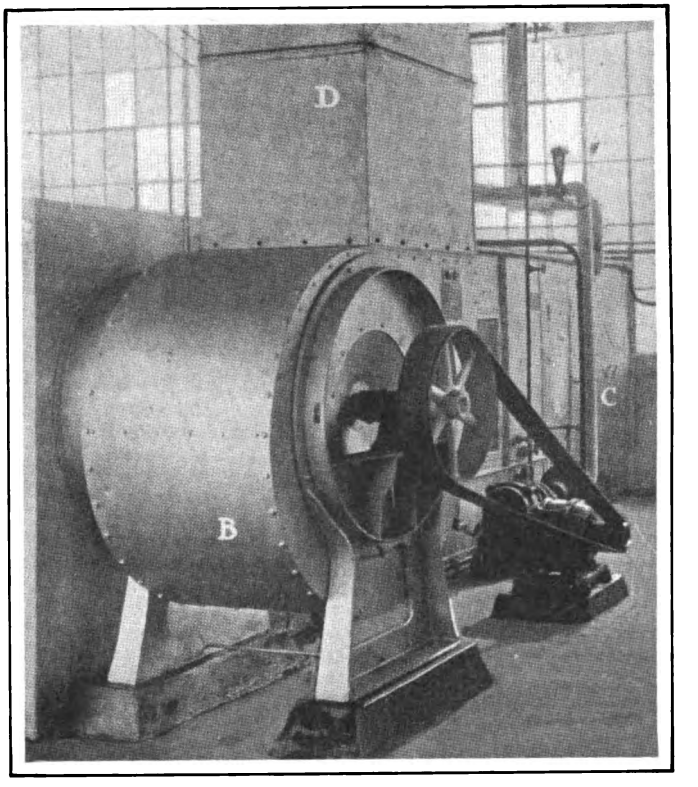
The Pickling Room

Coming from the manufacturing departments, some of the parts to be enamelled are first taken to the second floor. Here there is a pickling room measuring 35 by 70 ft., where the metal parts that have smooth flat surfaces, such as fenders, aprons and hoods must have an acid bath before they can go upstairs to the beauty parlors to be enamelled. Rust, finger marks and other foreign substances must be entirely eliminated from the surfaces of these parts before the enamel can be put on. Should a finger mark be left on the surface of a fender, for instance, the enamel would come off at that spot in less than three months. The same with rust and other substances. For the enamel to stay on, it must be applied to an absolutely dry and clean metal surface.

However, this pickling room visit is not required of the rougher metal parts such as step hangers, tire irons, bolts, and the like. The enamel has plenty of opportunity to stick to them providing they are wiped clean. These go directly to the enamelling department.

In the pickling room there are six vats each large enough to receive a fender or an apron, and above them, as protection to the workmen, are hoods which carry away the fumes. The first two vats contain a strong acid solution, the second pair have a weaker acid, and the others contain hot water only.

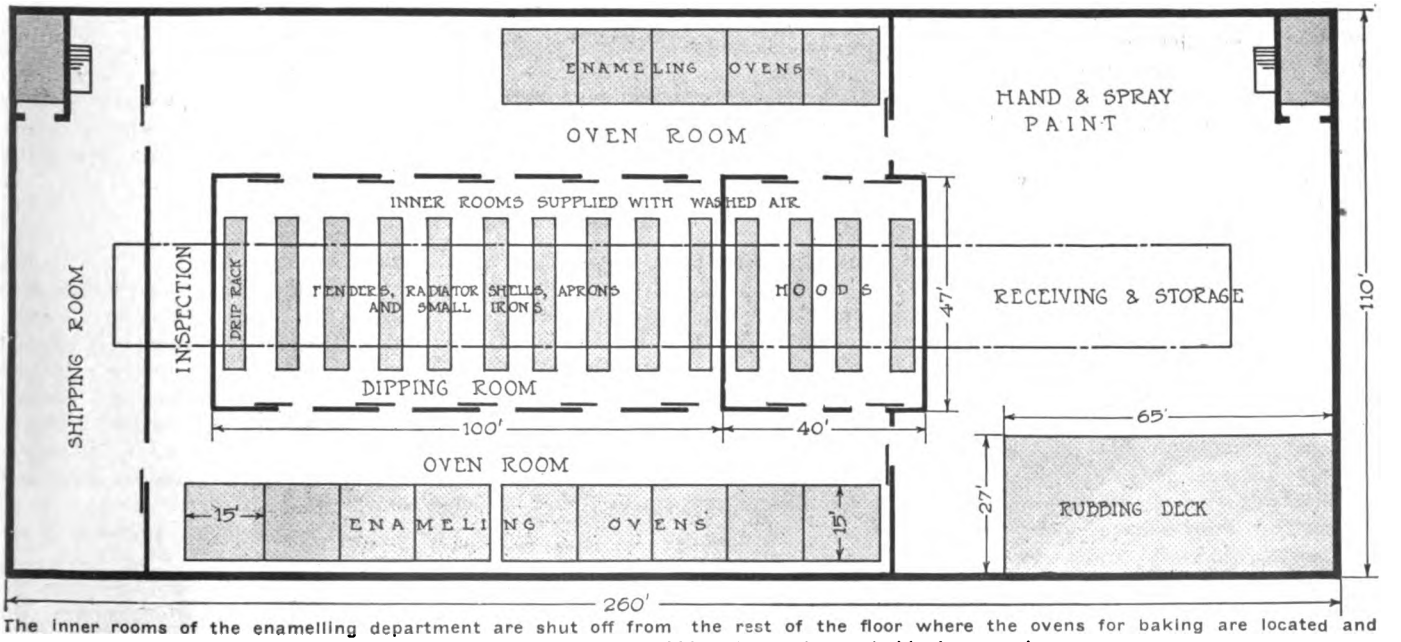
The procedure is to first dip the part in the strong bath,



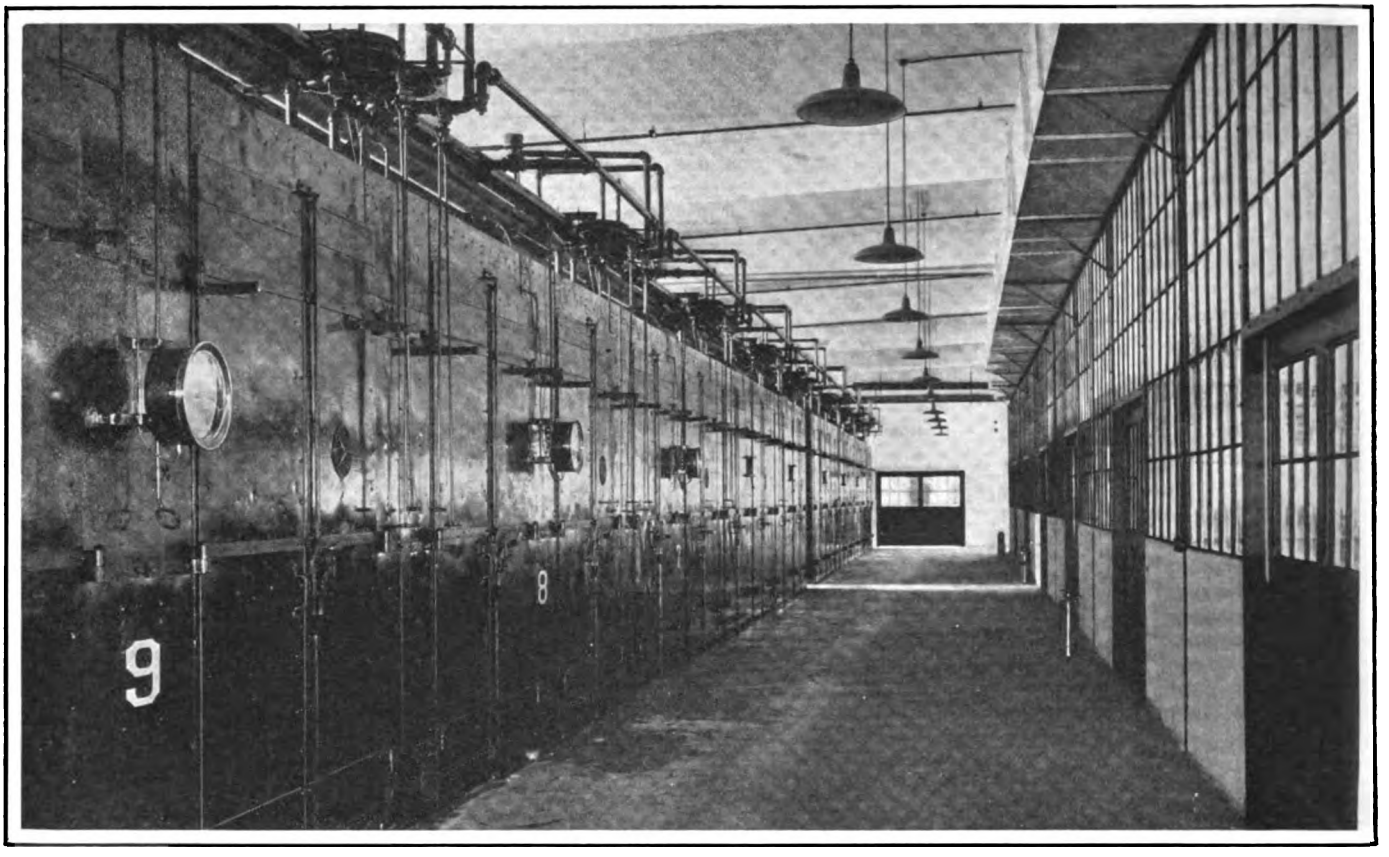
The large blower-type fan B which draws the air over a series of baffles, thus washing it. D is the air shaft and C is one of the pipes which carry the purified air to the inner rooms

then to transfer it to the weaker bath, after which the acid is rinsed off in the hot water. The piece is left in these acids only from 15 to 30 sec., and it is a solution which quickly eats off any rust. Following the baths, the piece is dried by directing a jet of compressed air onto it to get any acid out of the cracks, in addition to which a man rubs it with special cloths, always being careful not to put his fingers on the clean surface. The piece is now thoroughly cleaned and is ready to go to the next floor for the enamelling processes.

Here the campaign against the dust microbe begins in earnest. The actual dipping of the parts is done in two special rooms, which are virtually rooms within the main rooms. That is, they have four walls and ceilings, and are thus com-



The inner rooms of the enamelling department are shut off from the rest of the floor where the ovens for baking are located and where the hand and spray painting, rubbing, inspection and shipping are done



One of the banks of huge ovens used for baking the enamel on the sheet metal parts after they have had been dipped and drained. There are fourteen of these ovens

pletely inclosed within the main boundaries of the floor. Air which has been washed by a special process is circulated through these inner rooms, so that the purest of atmosphere is obtained.

Oiled Walls and Floors Kill Dust

But this is not all. It would be an easy matter for dust to reach the enamelled surfaces if the floors were not specially cared for. So, to further prevent dust, the walls and floors of these inside rooms are oiled. Once a week they are mopped in paraffin oil. Any slight amount of dust that might get in is thus caught by these surfaces and kept out of the air. But, you say, the men themselves might bring in some dust on their clothes. Buick has taken care of even this slight possible dust agency by requiring the enamellers to wear specially-prepared clothing, which absorbs any dust against its recirculation in the air. These clothes are furnished by the company at cost to the men.

Only black enamelling is done, and before it can be put into the dipping tanks, the enamel is first clarified and then mixed with oil to give it the right specific gravity, or thickness. The apparatus for clarifying somewhat resembles a cream separator. The centrifugal action of the apparatus throws off any impurities in the liquid. The clarifying is done to insure that only the clearest possible enamel is used. Having been properly mixed, the liquid is pumped to an overhead tank through the clarifier, and it then is strained back into a storage tank through a series of special gauze sheets ready to be drawn off into the dipping vats.

Arriving through pipes at these vats, the enamel is again strained through gauze before actually running into them, doing away with any foreign matter, however slight, that might have been collected in the pipes or connections.

Washed Air for Inside Room

The method of obtaining the washed air for these inside rooms is the same as that employed in theaters and other public places where they make a great feature of the washed air which their patrons breathe. For the dust pest is just as detrimental to an enamelled surface as it is to the lungs of the human being. The air is drawn by the suction of a large blower-type fan from outside through a series of baffles over which water is constantly playing. This literally washes the air, and the dust is trapped at the bottom of the air box. Reaching the blower after coming from its bath, the air is then sent through galvanized piping to the inner rooms. Ventilators are located near the floor, so that the air is kept circulating, since it is introduced to these rooms at the ceiling.

Separate Air Supplies

The two dipping rooms, which are thus proof against dust, are separated from one another by a partition, and each has its own supply of air. One room, in which hoods are dipped exclusively, has five dipping tanks, while the other adjoining room is provided with ten tanks and is used for aprons, fenders and radiator shells, principally.

Fourteen Baking Ovens

Along the length of the floor and outside of the dipping rooms are arranged the series of baking ovens, fourteen in number. Nine are placed on one side and five on the other for convenience. The floor plans show this arrangement clearly. Sliding doors in the sides of the dipping rooms allow the placing of the enamelled pieces in the ovens conveniently. These doors are of necessity kept closed at all times except when an actual transfer from dipping tank to oven is being made, for otherwise, the very purpose of the inner room would be defeated. It would never do for the air of the outside main room to get too well acquainted with the pure air of the inner room.

The dipping process is simple. We have seen how the parts are washed in acid and dried. Just before entering the inner room they go through one more procedure. They are

wiped with special dust-collecting rags, known as "tacky" rags. After all of this initiation, they are given the password to the inner shrine.

Dipping Hoods and Fenders

Two men do the dipping, one standing on either side of the tank. They use long hooks to catch hold of the hood or fender, drop it slowly into the tank of enamel, and then hang it over a drip pan at the end of the tank. It remains here for about 10 min., after which it is placed in the oven for 1½ hr., and baked at a temperature varying from 400 to 450 deg. Fahr.

Special racks are provided over the drip pans to accommodate the dripping pieces coming from the tanks, and the excess of enamel thus dripping off is drained back into the tanks. As many as forty fenders can be accommodated on one rack.

This first coat is known as the No. 1 "rubber coat," and following its baking on, the part comes back into the dipping room for the No. 2 rubber coat. The same dipping procedure is followed, after which another 1½ hr. baking is given it. Then a third or finishing coat is applied in the same way, and the piece goes into the oven for the last time, consuming another 1½ hr. Allowing 10 min. for each dripping, the actual time required to enamel a piece is 5 hr., figuring from the time the first dipping takes place to its final removal from the oven.

Special portable racks are used to hold the pieces while being baked and to convey them to the outgoing end of the floor after their final baking. These are specially shaped to receive either fenders, hoods or whatever other part is enamelled.

The ovens are a standard type made by Young Bros., Detroit, and designed to be heated by gas. They are constructed of sheet iron, and have provision for taking off fumes incident to the drying. They are about 15 ft. square and arranged to maintain the temperature desired.

Occasionally a fender or apron is marred or scratched in the assembly or in the course of painting, and to take care of any such, a rubbing deck is provided on the enamelling floor. This deck is about 20 by 60 ft. in size and provides for the preparing of the damaged piece for re-enamelling. The men smooth off the scratched places, and follow the usual procedure of making a piece ready for painting.

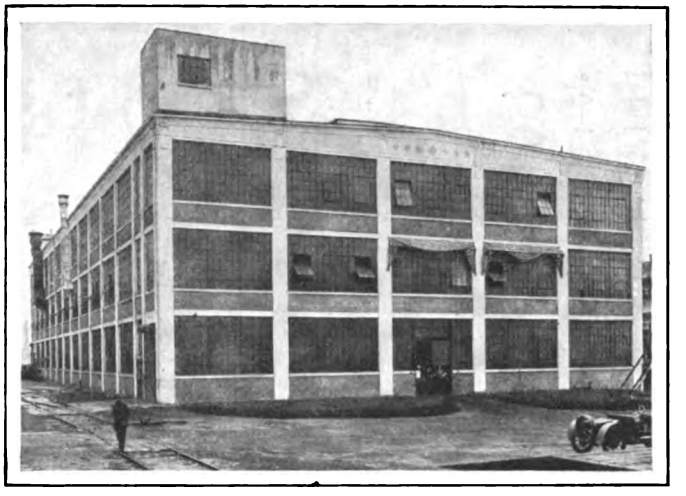
Baking the Wheels

No less interesting is the method of coloring the wheels on the floor below. Arranged around three sides of the wheel painting room are fifteen specially constructed ovens for the baking of the wheels. The room is approximately 80 by 100 ft. in size, and the ovens measure 10 by 10 ft. In the center of the room are the eight spray stands, each within a hood which carries away the fumes and gases, and confines the spray to the hood space. Each hood is about 3 ft. wide by about 4 ft. in height, giving plenty of room for the wheel, there being a dummy spindle on a stand to receive the wheel to be sprayed.

At the bottom of the hood there is a trap which catches the excess of the enamel, saving it for use again. The hoods connect through piping with a suction blower which carries away the odors, and also draws along some of the sprayed enamel suspended in the air. This is caught at the blower on a series of baffles and reclaimed.

Ovens for Wood Parts

The ovens are not like those used for metal enamelling, since they are not subjected to such high temperatures—130 to 140 deg. is about the average limit, due to the glue and sap in the wood wheels. Made of wood, the ovens are lined inside with galvanized iron, with a coating of asbestos between this and the wood. They are heated by steam, and the permissible temperature is 250 deg., although this is but rarely reached.



The new Buick enamelling building is three stories in height and 110 by 260 ft., giving a total floor space of 85,000 sq. ft.

Another series of hoods are also a part of the wheel painting equipment. These have to do with the sanding of the wheels and are twenty in number. The natural wood is first given a lead coat by hand, and before any of the color varnish is sprayed on, this lead coat must be rubbed down to a very smooth surface. This is done by hand with sandpaper, and has always been regarded as a dangerous occupation, for the sander is apt to breathe the tiny particles of poisonous lead as he rubs the spokes, getting them into his lungs.

The New, Safe Way

The hoods now used by Buick do away with this danger, for the suction draws away the dust, the sanding being done within the hoods specially provided for that purpose. Then follow the oil and primer coats, after which the color varnish is sprayed on.

The wheels come to the sprayer on double deck racks. Behind his hood he has two of these racks, one loaded with wheels ready for spraying and the other empty. He places the finished wheels on the empty rack, which, when loaded, is pushed into the oven. This spraying method is a remarkable time saver, for it requires but 40 sec. to finish a wheel. At the same time, the spray gets the paint into the pores of the wood and the isolated cracks in much better fashion than could be done by the slower hand process.

The wheels are baked for 1 hr. and 10 min. at the 140 deg. temperature, and they are then given their final varnish coat in the same way, another baking completing the job.

—

One Man Replaces Ten in Oldsmobile Wheel Department

New methods have been introduced into the Oldsmobile plant in the wheel finishing department and it is estimated by officials of the company that one man now does the work of ten in this phase of Oldsmobile manufacture. In former times, the finishing fluids were put on the wheels with a brush and a large body of workmen were required to carry out this work. Methods in this branch of automobile production have now become simplified and instead of the old brush painting method, the wheels in the Oldsmobile plant are finished by dipping them and then spinning them on a spindle revolving at high speed. By this method, the centrifugal force applies the finishing fluid much more evenly than would be possible with a brush and furthermore, one man can accomplish the work done by from ten to a dozen with the slower methods. The whole process of dipping and spinning a wheel requires not more than a few seconds.

High Spots in Design

1916 Models Show All-Round Progress—Multi-cylinder Motors, Reduced Weights, Simplified Chassis and Higher Efficiency

By A. Ludlow Clayden

IN succeeding issues of THE AUTOMOBILE, progress in the design and manufacture of different component parts of 1916 cars will be described in detail. In the following it is desired to touch merely upon the high spots; to review the situation in a very broad and general way. The broad view, if it is less instructive, serves to give a better perspective than is obtainable from a more detailed study; it is an almost essential preliminary to the latter.

Hardly ever before in the history of the automobile industry has there been a year so full of mechanical progress. Often in reviewing a year from the mechanical aspect it has been difficult to pick out the most important trend; has been a matter for debate whether the changes had been greatly for the better or not. During 1915, however, there is nothing to create doubt, though, of course, there may be discussion as to which of the different developments is destined to rank highest in ultimate importance.

V Engines Most Spectacular Novelty

Of course, the twelve-cylinder engine stands out as the most striking development with the coming into general popularity of eights as the second surprise. The eight has consolidated itself in a way that its most sanguine supporters would hardly have dared to predict a year ago, and the twelve has been accepted very quietly, as a natural development of the V-engine principle. It was just as bound to follow the eight as the six was bound to follow the four. Taking a long view over the engineering argument of the year on this subject of multi-cylinder engines, the conclusion has been reached that both varieties of V motor are good engines. The point remaining in doubt is the exact, best application of eights and twelves to automobile use.

The subject is intimately bound up with the question of weight. Till lately it has been assumed tacitly that the luxurious, seven-passenger car must necessarily be of a weight in excess of 4000 lb. With this as a basis the purpose of the twelve is easy to explain, but when it is shown that 1000 lb. or more can be cut from this weight, without affecting any quality of service, the position of the six is improved. Weight reduction is but just beginning and it is not yet possible to predict how little the ultimate automobile will scale. Till this knowledge is obtained it would be folly to attempt to place the future of different types of motor.

Small Twelves Coming

Next year we may expect to see twelves and eights with small total piston displacement and to thus have evidence for estimating where the advantages begin and end. One school of engineering holds that there is no need for any motor with more than six cylinders unless of a total capacity exceeding 400 cu. in., while another predicts a general use of twelves down to half this size.

American engineering in the automobile field can congratulate itself most heartily on the wonderful success of V motors. To create a type that is really new, and to make it in all qualities and for all prices, and to satisfy the public with each and every variety is no small accomplishment for a single, short year.

Perhaps the success of the V motor is all the more remarkable because in making new designs the engineers have, at one sweep, modernized everything. Crankshaft speeds have been raised, valve proportions increased, compressions altered and new lubrication systems adopted. In a broad way all these things have gone through without trouble above the trouble inseparable from new model production; the great changes have been no more difficult than the smaller ones of previous years.

The increase in motor efficiency is also partly due to the fact that much experiment has been made since 1912 with a variety of things that have all been brought to perfection simultaneously. The aluminum piston has been tried out here and there for many years and in 1915 it has come into its own. The various improved lubrication systems have similarly developed in experimental shops and all come into regular use suddenly. Engineers who had been studying cam design and rapid valve action for long, found the opportunity for the compete redesign they had been wanting. And so with many petty details, everything has been done at once, in a manner of speaking.

Carbureters a Large Factor

To the credit of the V motor must go a great change in the average excellence of carburetion, for the even torque of the eight and twelve have made possible, and desirable, crankshaft speeds far below anything attempted previously except on a few very costly sixes. This demand for good gas at ultra low revolutions, combined with good gas at crankshaft speeds far above previous practice, has led to many changes of detail in carbureters which all tend to make an already accurate instrument still more precise.

With the earlier eights it was found that the only way to get the desired "ability" was to use a mixture wastefully rich, and this dirtied the cylinders as well as costing much in gasoline. Now by perfecting the air and fluid mixing devices, by making valves move more positively, or by reconstructing nozzles, we are getting better ability with greater economy. Development along this line is certainly not yet at an end, but the advances made are much greater than appear on the surface.

What of Aluminum?

It is interesting, if idle, to speculate on what might have been the state of design had aluminum fallen in price instead of rising. The now almost "precious" metal ought to sell for a price not exceeding double that of casting iron, weight for weight, and it will do so one day when there is a sufficiency of plants for its production. Meanwhile its use in large quantities is confined to cars of moderate and high price. It may be that the aluminum cylinder motor will in the future come to be seen as the most important development of 1915. It may outshadow the multi-cylinder engines and everything else.

At present all that can be said is that there are many motors with aluminum cylinders that are giving the greatest satisfaction in use. That these motors are much lighter than the ordinary, cost no more to machine and assemble and are easier to cool efficiently.

Conversely, we desire experience to show whether the

metal will withstand long use, year after year, and whether the price will fall sufficiently to make wider use of aluminum commercially possible. Also there is the possibility that the lightness obtainable with aluminum may provoke other experimenters to devise ways for using sheet steel which will give equal strength and satisfaction with equal lightness. At present, light metal seems the easiest and best way of obtaining light chassis.

Light Weight Spells Low Cost

The ratio of the cost of the metal in an automobile to the labor has changed and the cost of producing a car complete can be gaged in a rough way by its weight, if the standard of engineering is about the same. Thus refined design which enables weight to be cut, assists the manufacturer just as much as it helps the man who has to pay the gasoline and tire bills.

The present year has seen the beginning of light weight work on the part of engineers generally. There have been some who have realized its advantages for years, and built light weight cars, but it is only lately that the attention of the majority has been attracted to this most vital problem.

Spiral Bevel Generalized

Hand in hand with higher efficiency motors, running at higher speeds we see the spiral bevel gear for rear axle transmission has come into general use. Last year it was employed on many chassis, but it was confined mainly to machines of high price. Lower gear ratios to give greater high gear ability are now the rule, and it is difficult to find room in an axle case of reasonable size for straight tooth bevel gears with a ratio much below 4 to 1. With the spiral bevel, however, the task is easy.

Another reason for the popularity of the spiral form of gear is that it is naturally quiet in operation. This was known years ago, but that the new gear was as durable as the straight tooth form had to be proved and was proved by the 1915 model cars. Thus on the 1916 machines the spiral bevel is used almost always, except where cost is an extremely important consideration.

Even then the position is rendered difficult of judgment, because the number of spiral bevel gears asked for by automobile manufacturers has exceeded the possible output. The machine which made the spiral bevel a commercial possibility is new and its makers have only been able to supply a proportion of those they have on order. This being the case the spiral bevel ought to be cheaper next year and to come into wider use than ever.

Gearing Changes Little

In gearset and rear axle design but few innovations have been made. Probably the most striking development is the discontinuance of the rear axle location for the gearset by the Packard Company, who have been the leading exponents of this design for so many years. Generally, the use of the unit transmission is declining, mainly because the unit power plant is a better proposition from a manufacturing viewpoint. It is possible to see a slight trend toward the use of double internal brakes on the rear axle, but the point is debatable, because axle manufacture is confined mainly to a very small number of firms, and these have been far too pressed by unprecedented business to consider changes of design even of the slightest.

One development which was expected by some people and has not transpired, is the electrically operated gearshift, another is complete electric transmission. With respect to the latter, however, it must not be forgotten that the Owen Magnetic car has been far more successful commercially and practically than most of the trade anticipated, and it is to be supposed that this will not be without effect upon engineering thought in general. The placing on the market, and selling in regular, if small, production of a passenger car with an all-electric transmission deserves a prominent place, however, in any list of mechanical achievements of the year.

Better and Cheaper Materials

Thanks largely to the accumulated labors of the S. A. E. Steel Standards Division, the average of quality of fairly good steel has been raised quite perceptibly, because the creation of standard specifications has assisted steel makers to discover better methods. It has been possible to tighten the limits of accuracy for chemical constitution of many steels, and users find that a more regular quality is coming to them, without an increase in price. This has had a levelling effect because it has helped to offset the slight general rise in the price of cheap steel due to the huge demand for purposes other than automobile making.

Chassis Layout Simplified

As was pointed out in a recent article, the reduction in the price of automobiles has largely been due to a simplification of detail and the elimination of parts which have proved needlessly cumbersome or altogether valueless. For instance, brake rod layouts have often been redesigned so as to eliminate a number of brackets and links. Likewise the pedals and steering gear now commonly make up with the power plant instead of being separate frame attachments.

More important still, in the detail *of* the detail simplification has been the rule. Stampings and pressings have replaced castings to a much larger degree than formerly. Die casting is becoming more popular for all sorts of small parts. Block motors eliminate the necessity for pipes and couplings. Perhaps this tendency is most conspicuous among accessories and fittings. Lamps, switches, control details and such like, are now more often die castings or stampings than anything else, yet a short time ago heavy, expensive brass castings found a large use in their makeup.

Battery Ignition Gaining

It would be a nice point to decide how much price has influenced the ignition situation, and equally delicate to forecast the future of ignition mechanically. Whatever opinions may be held, however, the fact remains that battery ignition has gained in favor enormously. It has improved too, being vastly better in detail than a few years ago. Makers of distributers and contact breakers have taken a leaf from the magneto manufacturers' book and utilized similar materials with similar care and accuracy, so the reliability of battery ignition now rests mainly upon the battery and the generator which keeps it charged.

Batteries themselves are improved a little in mechanical detail and generators in both electrical and mechanical efficiency, so the battery ignition that has come through this season without mishap stands an even better chance next year. None the less the magneto has not stood still and remains the standard ignition where performance is considered above everything else, with one or two exceptions.

Bodies Are Larger

Bodies generally are larger, of better appearance and more comfortable. On the matter of size it is possible that manufacturers have gone a trifle too far, because many of the seven-passenger cars of 1916 type are not good to ride in with less than five passengers aboard. Four people are usually much better suited by a close coupled design and not too great a width of seat, and the rapidly growing popularity of clover leaf three seaters, small four-passenger jobs and roadsters with a single seat wide enough for three, shows clearly that whatever the *majority* demand may be for, there is a large class that prefers a less spacious body.

Parlor car front and sometimes rear, seats are another development of the year and at present look as though their popularity would lead to a wider use of the design next season.

German Army Transport

Heavy Consumption of Automobiles and Trucks Points to Shortage After War—Large Field for American Products

By E. A. Langdon

HANOVER, GERMANY, Aug. 30—There were some 70,000 motor vehicles, including passenger cars and trucks, in Germany when the war broke out; to-day there are fewer than 15,000. In the Dual Monarchy, Germany's ally State, there were more than 30,000; to-day there are considerably fewer than 10,000; in other words, the civilian population has lost the services of some 75,000 motor vehicles in Germany and Austria-Hungary. These vehicles are now rendering yeoman service in the campaigns in the east and west and were largely responsible, it is said, for the rapid advance of the Germans in France during the first three weeks of the war in 1914, as well as for the manner in which the German army in Poland stemmed the Russian tide and severely defeated the Czar's hosts a number of times.

It would be going too far into details to consider here the thousand and one ways in which the transportation system has rendered the Kaiser's army as efficient as it has. But from the descriptions of the several special newspaper correspondents, who have been permitted to visit the front, and from the tales of wounded soldiers who have been sent to the interior of Germany, it is obvious that the importance of the motor car to Germany to-day is on a par with that of the other two classes of military equipment, which have revolutionized modern warfare; namely, heavy rapid-firing artillery and aerial scouting service.

In addition to facilitating the transports of troops and materials of all kinds, the motor car has done invaluable work for the "Sanitaetswesen," hospital division, and has taken over a great deal of the work formerly exclusively handled by the cavalry; namely, reconnoitering and carrying of rapid dispatches.

Car Supply Maintained

In addition to the approximately 75,000 motor cars taken into German and Austrian army service at the beginning of the war, many thousands of vehicles have been turned out by the car factories of both countries. Many plants are working seven days a week and twenty-four hours a day, and in not a few cases have the vehicle designs and the production machinery been adapted to the specific requirements of the strenuous army service. It will probably take a long time ere the details of this wonderful adapting process, planned and carried out even while the armies were battling on the borders of the Empire, will become generally known. The effect of this system, however, is that the number of motor vehicles now in service is even greater than that available at the outbreak of the war; for not only have the factories worked at maximum capacity, but thousands and thousands of owners whose cars were not requisitioned by the government have put and are still putting their vehicles at the disposal of the fatherland; in many cases they also serve as volunteer drivers if they were not called into the army already.

Of course, a great many vehicles are destroyed or damaged, due to the terribly hard work. The remainders of the former are taken to the interior of the country, to be refashioned and reused as best they may, while the injured cars and trucks are taken to the nearest "Automobillazarett," automobile hospital, to undergo quick but thorough repairs. It is almost impossible to learn the details of these elaborate repair works, five of which are said to exist along the western front and four along the eastern; the Austrians also have one automobile hospital in the east of Galicia, near Cracow. In these places the work is also carried on incessantly.

Like everything else in war, the motor car equipment is being worked at maximum capacity. If the cars are used for troop transports, a touring car designed for five or seven passengers is frequently made to accommodate twenty soldiers. The effect on motor, running gear, etc., especially the spring suspension, is obvious enough. But if there is any way at all in which 25,000 cars can be made to quickly carry 500,000 fighters from one point of the front to another—often 100 or 200 miles away—the expense of the process must necessarily be ignored. Thanks to the fact that

"—beyond a doubt,
A chaise breaks down, but doesn't wear out—"

one part of the car after the other may be injured and repaired and the whole vehicle still remain useable.

New Factories Created

Another fact which is positive enough, although it is very difficult to obtain detailed information about it, is that many machinery factories, the products of which are not needed or not badly needed while the war goes on, have been transformed into automobile or parts factories. This still enhances the supply of available motor vehicles.

Thus, there seems a foundation for the assumption of the German military motor experts that the Kaiser will have all the cars and trucks he needs, even if the war should go on for years.

It should be remembered, however, that what is fair in war is not always considered so in times of peace. After the conclusion of the peace the owners who have willingly sacrificed their machines on the altar of the fatherland will undoubtedly make wry faces when their cars are returned to them. Every machine will be badly battered and shaken through and practically unfit for pleasure use. The trucks, too, will have suffered to such an extent that their operation will be much more expensive than before, due to ever recurring high repair bills and high fuel consumption. A few weeks after the war it will dawn on nine out of every ten owners that the best course for them to take is to buy new vehicles.

From where are these vehicles to come?

Shortage with Peace

The German factories' capacity will be far short of being able to supply the demand. There will be a call for from 50,000 to 80,000 new motor cars and trucks in Germany, and perhaps 25,000 in Austria-Hungary; as not only will the cars destroyed and spoiled by the war have to be replaced, but tens of thousands, perhaps hundreds of thousands of horses killed during the war will have to be supplanted by motor vehicles. The prediction made by many experts during the early days of the war that the war will serve to motorize Europe will come true.

German factories will of course attempt to supply the de-

mand as far as possible, but will be hampered both by a shortage of labor and by a lack of capital. The shrewd German manufacturers will undoubtedly reason that it is not good business policy to increase their factory equipments to a very great extent for the immediate supply of the great demand, only to be a year later with superfluous equipment or superfluous stock which could not be sold profitably on the world's market. Furthermore, the scarcity of money will in itself be a hindrance to a general increase of capitalization.

Hence, Germany will look to other countries to supply at least part of her great motor car demand.

It is safe to say that Germans will buy as little as possible in the way of English and French-made goods. Probably Switzerland will therefore supply many high-priced cars to Germany. In addition, the Belgian industry may find a German market depending on the friendliness of the relations of these two countries after the war.

For, there will enter more sentiment into business matters after this war than ever before. The commercial relations between the now belligerent countries will be mended much later than the political ones, and in this fact lies the great advantage of the nations which remain neutral through the full time of the conflict.

For this reason, and also because of its ability to produce standard, efficient, moderately-priced passenger and commercial cars, the United States should be in a position to sell myriads of cars to German buyers. This, however, will not be as simple and as easy as might appear at first glance, for reasons which will be given a little later on.

America's Opportunity

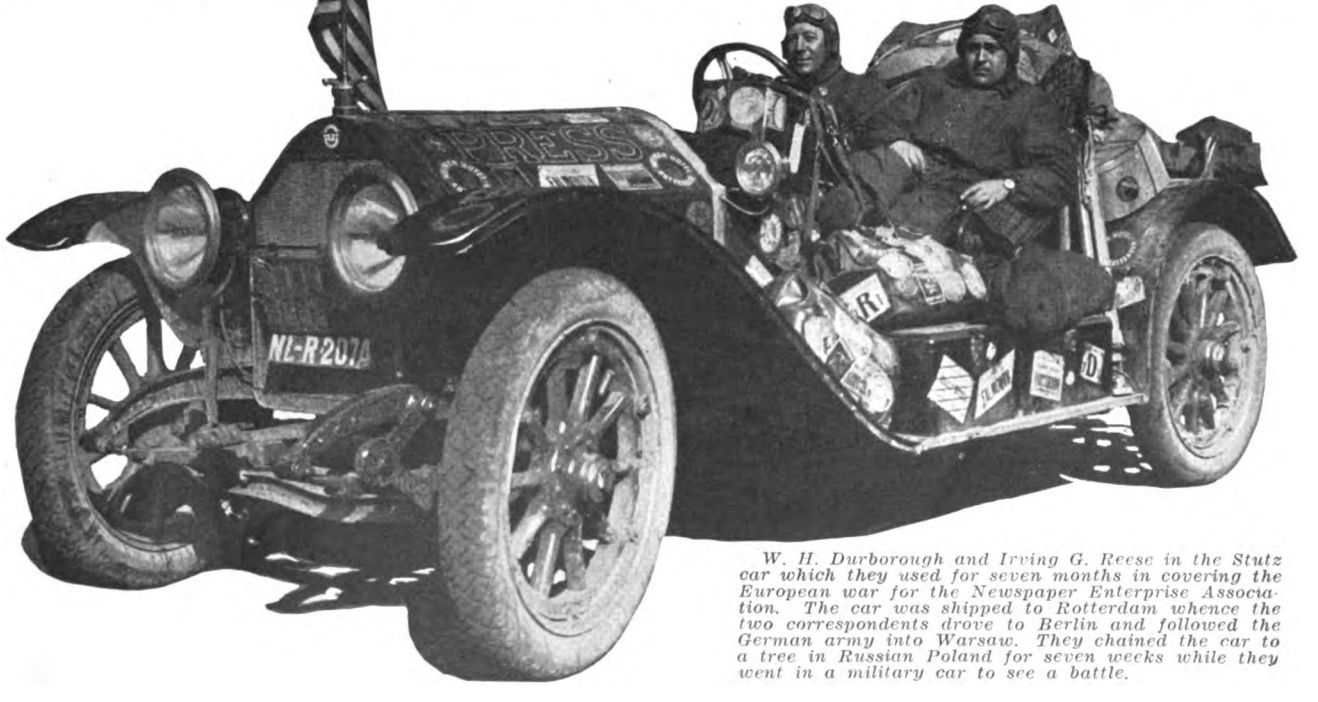
Standard American products, sold intelligently by American methods and at American prices, have long since found a good market in Germany as well as in Austria-Hungary. All kinds of machinery, including machine tools, typewriters, phonographs, motor cars and motorcycles have been welcomed by the Germans if introduced in the proper manner. Especially is this true of motor vehicles, for the number of motor cars per head of the German population is from one-tenth to one-eighth of that in the United States, although the economic power of the average German is certainly not less than half of the average American. The difficulties consist in the slow and careful thinking of the Germans, who give much thought to such a matter as the purchase of a car or truck before they spend the money. A car must be so designed, internally and externally, as to be suitable for four to five years' use. Simplicity of design and color, strength of construction and relatively low fuel consumption are wanted by German buyers. Service is another important point. Not one German buyer in ten will purchase a car unless it is backed by years of satisfactory performance and unless the company keeps a stock of spare parts within a few hundred miles of his place of abode.

Despite these difficulties, a number of well-known, standard, well-equipped, medium-priced American makes have been successfully introduced into Germany and Austria-Hungary. As the foregoing explanations indicate, selling in these countries is not as easy as in America; but, nevertheless, splendid business has been done by the efficient selling organizations of these concerns.

There is another difficulty about this situation, which has been brought out, in fact, created by the war, and which will continue to be effective for a considerable length of time after the cessation of hostilities. It might as well be admitted that there is a widely felt lack of sympathy for America in the realm of the Kaiser. The reason is simple. Germans do not realize the geographic, commercial and political position of America very well, and there is a widely prevalent idea that Germany had deserved a more friendly treatment from America than it got since the beginning of the war. This feeling may be poorly founded, but its existence is an indisputable fact. Hence, the American is not looked upon with the same amity to-day as he was a year ago. The fact that English is the only language spoken by a great many Americans hardly helps to alleviate the situation; it rather has the opposite effect.

Salesmen Must Speak German

This fact has the following bearing on the commercial situation. The average German, after the war, will be loath to deal with a salesman who does not know the native language. It is to be presumed, in fact, that a salesman not in command of German will be at a very great disadvantage. Even a foreign accent will be looked upon in the nature of something unfriendly to Germany—of course, only by the little business man; but these people, after all, constitute the largest class of prospectives in Germany. Therefore, companies starting an export campaign in Germany after this war should be careful to equip their salesmen with a knowledge of German; in Hungary and Bohemia, the languages of these countries should be known by the salesmen.



W. H. Durborough and Irving G. Reese in the Stutz car which they used for seven months in covering the European war for the Newspaper Enterprise Association. The car was shipped to Rotterdam whence the two correspondents drove to Berlin and followed the German army into Warsaw. They chained the car to a tree in Russian Poland for seven weeks while they went in a military car to see a battle.

It hardly needs to be mentioned that, selling being less simple than at home, the salesmen will require some diplomatic ability to do business.

Among the many developments brought about by the war is also the following one, in the fuel situation. It is an admitted fact that Germany, on account of a shortage of gasoline, has taken resort to benzol and alcohol. Most probably, the fields of these fuels will increase after the war, and many thousands of German car owners will insist on using benzol, for economical and patriotic reasons. Alcohol, too, can be very easily and cheaply produced in Germany, as this country is the leading potato grower of the world. Hence, it would pay for American manufacturers to experiment with adaptations of their motors to these two fuels. The very argument that benzol or alcohol can be used in a car will enable its salesman to get a better price for it than he could if the machine needed gasoline for its operation.

Government initiative in Germany and Austria has grown very strongly during the war, and very probably will continue to do so after. It is safe to assume that the governments will do their best to further the home industries producing these two fuels and that the population will follow their lead with enthusiasm. This renders the point of a motor applicable to non-gasoline fuels of eminent importance.

Tire Market Temporary

Tires will probably find a very ready but short-lived market after the war. If American makers will be able to supply large quantities at most reasonable prices, they will be able to do a great volume of business in a very short time. It is reasonable, however, to assume that the artificial rubber question is also being solved, as so many other problems, under the pressure of the war. If this is the case—and indications seem to point in this direction—then Germany will very soon produce enough cheap synthetic rubber to supply its entire demand for tires.

Several classes of accessories, such as starters, lighting equipments, automatic tire pumps, etc., should also find a good market, provided the products are reliable, simple and reasonably priced.

American motor car manufacturers who are not represented in Central Europe at this time and intend to break into the German and Austrian markets after the war, would do well to send one or two intelligent representatives to these territories without delay. These men could gather valuable information about conditions in general, about the experiences with the different types of vehicles in the war zones, about the sentiment of the people; they could outline a sales campaign to be carried out after the war; they could form valuable business connections, etc. As already stated, it is highly important that these men be possessed of practical intelligence and a strong instinct of how to act and what to do.

One thing is certain. American car manufacturers will have an unprecedented opportunity in Germany and Austria-Hungary after the war. The advantages of the opportunity will go to those who are able to see its magnitude now and who prepare for its utilization, so that when the right moment comes, the business may be carried through efficiently.

Three Models in Partin-Palmer Line

FOR 1916 the Partin-Palmer line, built by the Commonwealth Motors Co., Chicago, Ill., will consist of a light five-passenger touring car known as the model 32 and listing at $675, fully equipped, a six-passenger at $975 and a roadster for $495. The power plant consists of a four-cylinder motor 3½ in. by 5 in. and has a three-point suspension. The cylinders are block cast with spacious water-jackets the water inlet being located in the center of the cylinder block opposite the valves and at the bottom of the jacket, permitting a complete drainage through the radiator. The cylinder head is cast separately, allowing ample space for valves and enabling proper setting of cores and even thickness of walls, designed to give greater efficiency to the cooling system.

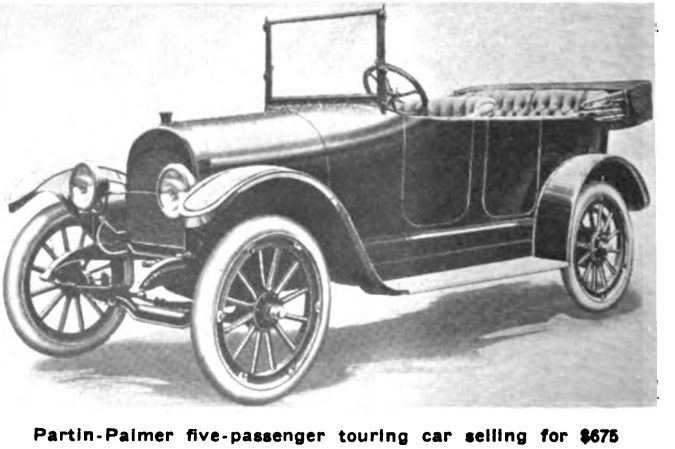
The crankcase is of reinforced aluminum cast in two sections and completely incloses the flywheel and multiple disk clutch. Heavy webs are provided for supporting the crankshaft bearings with provision made for removing the bearing caps easily. An oil pan having a capacity of 5 qt. is bolted to the bottom of the crankcase. Any of the connecting-rods and pistons may be removed without disturbing the adjustment of the main bearings. Lubrication is by constant level splash, the level being maintained by a plunger pump driven by an eccentric on the camshaft. Cooling is by thermo-syphon.

Crankshaft bearings measure 3¼ by 1¾ in. front, and 3 15-16 by 1¾ in. rear; the flange to which the flywheel is bolted is integral with the crankshaft and the connecting-rod bearings are of the split type measuring 2⅜ in. by 1¾ in. The camshaft is 1 in. diameter with cams integral, and is supported by three bearings. The valves are 1⅜ in. in diameter fitted with gray iron heads and steel stems.

The three-speed gearset is placed in a unit with the motor, the gears and shafts being of liberal size, while annular ball bearings are used throughout. Drive is taken through a 1¼ in. shaft completely inclosed in a torque tube supported at the forward end by a yoke which is attached to the transmission housing instead of to a cross member of the frame. A double universal is placed between the forward end of the propeller shaft and the transmission, while adjustable radius rods extend from the yoke to the rear axle.

The rear axle is floating with a gear ratio 4 to 1 and provision is made for adjustment of the differential without removing the rear plate from the housing. The driveshaft is fitted with New Departure ball bearings. Brakes are expanding, both emergency and service being fitted with equalizers. The rear springs are three-quarter elliptic underslung and the front semi-elliptic.

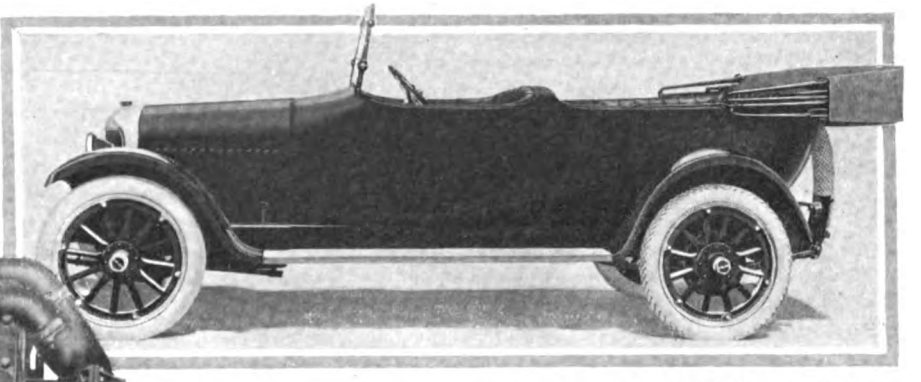
Body design follows yacht lines and the wheelbase of 110 in. affords ample seating capacity for three passengers in the rear seat, which is 50 in. wide. The gasoline tank, which is placed in the cowl, has a capacity of 10 gal. The body is finished in dark olive green and the fenders and hood in black enamel, while the wheels are red. Tires are 32 by 3½ and the car is fitted with non-skids on the rear wheels. Equipment includes electric starting and lighting. Connecticut ignition, electric horn, Stewart-Warner speedometer, one extra rim with carrier, windshield and one-man top.

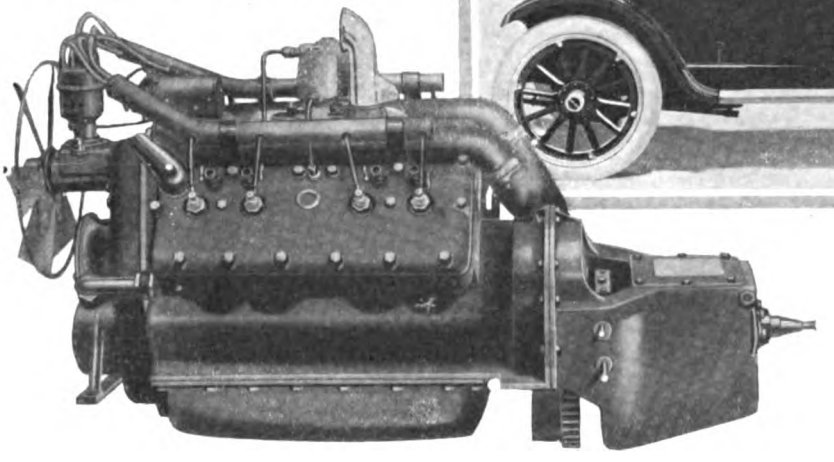


Partin-Palmer five-passenger touring car selling for $675

Oakland Adds Eight-Cylinder Model

3½ by 4½ Cylinders Give 346.4 Cu. In. Displacement —71 Hp. at 2600 R. P. M.





Above—The new Oakland eight-cylinder touring car which is built only as a seven-passenger type, the chassis having a wheelbase of 127 in. With complete equipment this car sells for $1,585

Left—Eight-cylinder 3½ by 4½ in. motor used in the Oakland. This motor has a counterbalanced crankshaft made by forging crescent-shaped counterweights integral with the crank arms. Another feature is the use of aluminum pistons

ANOTHER of the prominent automobile manufacturers—the Oakland company—has fallen in line with an eight-cylinder machine, which is considered the best appearing car yet built by the Oakland Co. The characteristic V-shape radiator with German silver finish has been used, and the slope is from this point backwards in a practically unbroken line.

Although designed for exceptional roominess, the car has not the appearance of weight, and there is a surprising amount of room in the tonneau. The auxiliary tonneau seats are of the disappearing form, folding into the back of the front seat, out of the way when not in use. The new Oakland is built only in seven-passenger type, at present, and has a wheelbase of 127 in. It is to sell at $1,585 with complete fittings.

Low Without Sacrificing Clearance

This eight, like other cars of the Oakland make, is carried low to the ground without sacrificing road clearance. The springs have much to do with this feature, the rear set being underslung. Cylinder dimensions of the motor are 3½ in. by 4½ in., giving a displacement of 346.4 cu. in. with a formula horsepower rating of 39.22. It has developed 71 hp. on the block at 2600 r.p.m., however. Other specifications include the complete Delco ignition, starting and lighting installation, cone clutch, three-speed gearset in the motor unit, open driveshaft with two universals with the Hotchkiss principle employed, one-bearing floating rear axle, three-quarter elliptic rear springs, 34 by 4½ tires, and left drive with central control. The carbureter is a Stromberg, and is fed by the Stewart vacuum system.

Ample power is invested in the engine to secure excellent performance at all speeds. It has a wide range of flexibility, will throttle down to a walking pace, and possesses quick pick-up to high speed. It is to be expected that an engine of this power would handle such a vehicle with great satisfaction to the owner, especially that type of driver who is adverse to manipulating the speed-change lever.

This eight is of the type in which the crankcase is split vertically, each half being cast in unit with one block of cylinders, and the two bolt together to form the complete engine. A stamped oil pan attaches to the bottom; the gearset bolts to the rear of the built-up crankcase; and there is another stamping to house the front driving gears and chain. Removal of the steel oil pan exposes all of the bearings and the camshaft with its contacting tappets. The left half of the crankcase carries the camshaft and crankshaft, the caps for the bearings facing the other half of the crankcase.

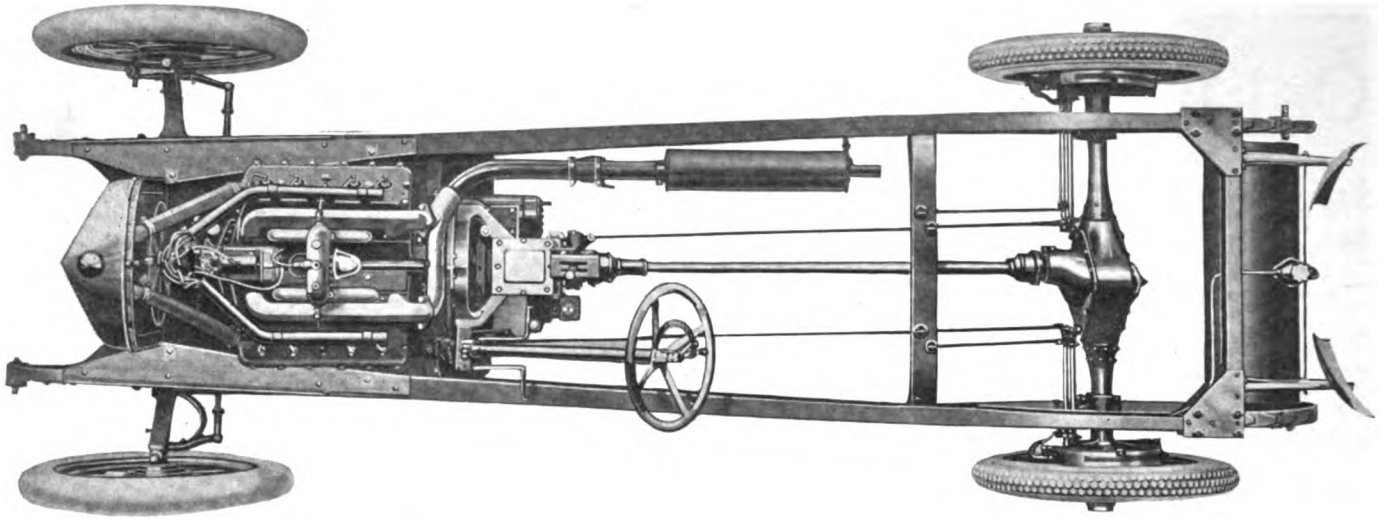
In the general layout of the powerplant, the various units are all very nicely taken care of, and there is nothing which can be criticised from a practical engineering standpoint. The cylinder heads are detachable, providing for access to the pistons and valves through the top, as in most motors now made with the crankcase and cylinder block in unit. Thus the desirable feature of being able to get at the pistons quickly has not been sacrificed, and rigidity is still maintained.

A single camshaft is used, there being a separate cam for each valve. In order to make the valve pockets as short as possible, and at the same time to use one camshaft, the valves have been inclined to the cylinders sufficiently to bring them out at the bottom and close to the combustion chambers at the top. From an external glance at the engine it would seem impossible for each valve to have its own cam, since the cylinder blocks are directly opposite one another. They are in reality staggered sufficiently to allow sufficient room for the tappets and cams side by side, the offsetting of the cylinders with respect to those on the opposite side being done within the castings.

Standard practice obtains for the valve mechanism with the exception of the seating of the valves on an angle as already mentioned. The tappets are provided with rollers and drive of the camshaft is by gear connection with the crankshaft directly below.

All Shafting Inclosed

On the outside of the camshaft gear is a sprocket over which runs a silent chain to drive the fan and generator shaft, which is also vertically above the crankshaft and camshaft. The front end of this upper shaft drives the fan; at its center it drives the ignition distributer; and at the rear the generator couples on. So a very compact assembly is attained, the end of the generator protruding only a short distance into the front of the V. The steel cover very neatly



Plan view of Oakland eight-cylinder chassis showing layout of unit power plant, Hotchkiss drive, etc.

encloses the whole driving apparatus, and another housing extends out from the top of it to enclose the small shaft at the top, forming a mounting for the distributer at the same time. There is, therefore, no exposed shafting whatever, a feature which should work to the advantage of the mechanism, since any enclosed apparatus should necessarily be proof against dust and dirt, should be better lubricated and less noisy.

A feature of the engine is the counterbalanced crankshaft. This is made by forging crescent-shaped counterweights integral with the crank arms, one to counterbalance the weight of each set of rods. There is a weight protruding from the main bearing end of each arm, making for correct balance of the rotating parts, and taking care of the oscillatory effect of the connecting-rods. The counterbalancing is done to reduce vibration from this source to the minimum, with the result that a very smooth running engine is secured. In fact, there seems to be no periodic vibration at any speed within the possible driving range.

Aluminum Pistons Used

Oakland is using aluminum pistons successfully in this engine, they also playing a part in the promotion of sweet running at high speeds. Connecting-rods are of the forked type mating with small-end rods on the opposite side. The camshaft is a carbon steel forging, and like the crankshaft, has three bearings of phosphor-bronze.

For the sake of balance, there are two yoke-end rods on one side and two on the other. The yoked rods have bronze-backed, babbitt-lined bushings, which, besides being clamped in the rod ends, are pinned to prevent rotation. The inner rods oscillate on the outside of these bushings and, while the ends of the forked-rods are not adjustable, the inner rods can be adjusted by the use of shims. However, in an eight, where the oil pressure is high, and where special bushings such as these are employed, adjustment is not required, and with proper care they should run satisfactorily for a long period—probably two seasons at least.

The crankshaft bearings have these dimensions: Front, 3⅛ by 2 in.; center, 3 by 2 1/16 in.; rear, 3 15/16 by 2⅛ in.; connecting-rod bearings (on crankshaft), 2⅛ by 2⅛ in.

Pressure running from 30 to 40 lb. per sq. in. is used in the oiling system when the engine is running at high speed, after being warmed up. At normal speed it probably rises to about 20 or 25 lb. per sq. in. The pressure is produced by a gear pump on the front end of the crankshaft, housed in the lower part of the timing gear case. The oil is drawn from the base, and then sent through a pressure regulating valve, after which it goes directly to the main bearings. From there it runs to the rod bearings through holes drilled in the webs of the crankshaft. The pressure regulating valve is fitted with a by-pass, and when the pressure for which it is set is reached, this by-pass is opened and the overflow runs to the camshaft bearings and to the timing gears and chain. The spray from the connecting-rod bearings is thrown up into the cylinders to lubricate the walls and pistons.

A filler and breather pipe is placed on the right side of the front gear cover. This makes a most convenient location for a filler, as it is an easy place to reach with the oil supply.

Delco Electric System

The electric system is entirely Delco. Positions and method of drive of generator and distributer have already been touched upon. The starting motor, which is entirely separate, is hung from a supporting bracket on the right rear of the power plant alongside of the gearset. The starter drives through the flywheel, with the teeth of which the pinion on the end of the starter motor shaft meshes. The Bendix type of connection is used, in which the meshing and demeshing is entirely automatic when the current is sent to the electric motor.

Adequate cooling facilities are provided by a double centrifugal water pump, cleverly mounted on the front end of the camshaft extension and outside the timing gear housing. In this position the pump drive could not be much simpler, and at the same time, there is the advantage of having the pump equi-distant from each cylinder block so as to assure uniform circulation. The intake pipes run from top and bottom of the pump to the front of the cylinder castings.

Fan Drive by Friction Clutch

The fan drive is through a friction clutch on the end of the generator shaft, and the fan can be turned by hand, but the clutch has sufficient tension to prevent slippage when the engine is driving it. The center of the fan encloses a coil spring which bears at one end against a plate on the end of the shaft and at the other against the fan, thus making a friction connection. Such a friction arrangement is used to safeguard the drive.

On the left side of the gearcase is mounted a Stewart single-cylinder tire pump which is driven from the reverse idler gear. It is operated at 2.6 times engine speed and is readily thrown into mesh.

Six springs equally spaced around the clutch cone hold it in engagement, and there is also a clutch brake to prevent spinning and make for easy gear shifting. The gearset uses ball bearings, and the gears are of high carbon chrome-nickel steel. A form of yoke surrounds the flywheel to carry the gearbox, leaving the top and bottom of the flywheel exposed for timing purposes.

Final drive is made very simple through adherence to the

Hotchkiss drive system which has featured Oakland cars for several seasons. The propeller shaft is tubular and of open construction with a universal at gearbox and axle ends. No torque arms or radius rods are used, but drive and torque are taken through the springs, the master leaf of each rear spring being designed for the service.

To how great an extent simplicity has been attained is shown very clearly indeed by the chassis plan view on the opposite page; the chassis is as handsome as the car.

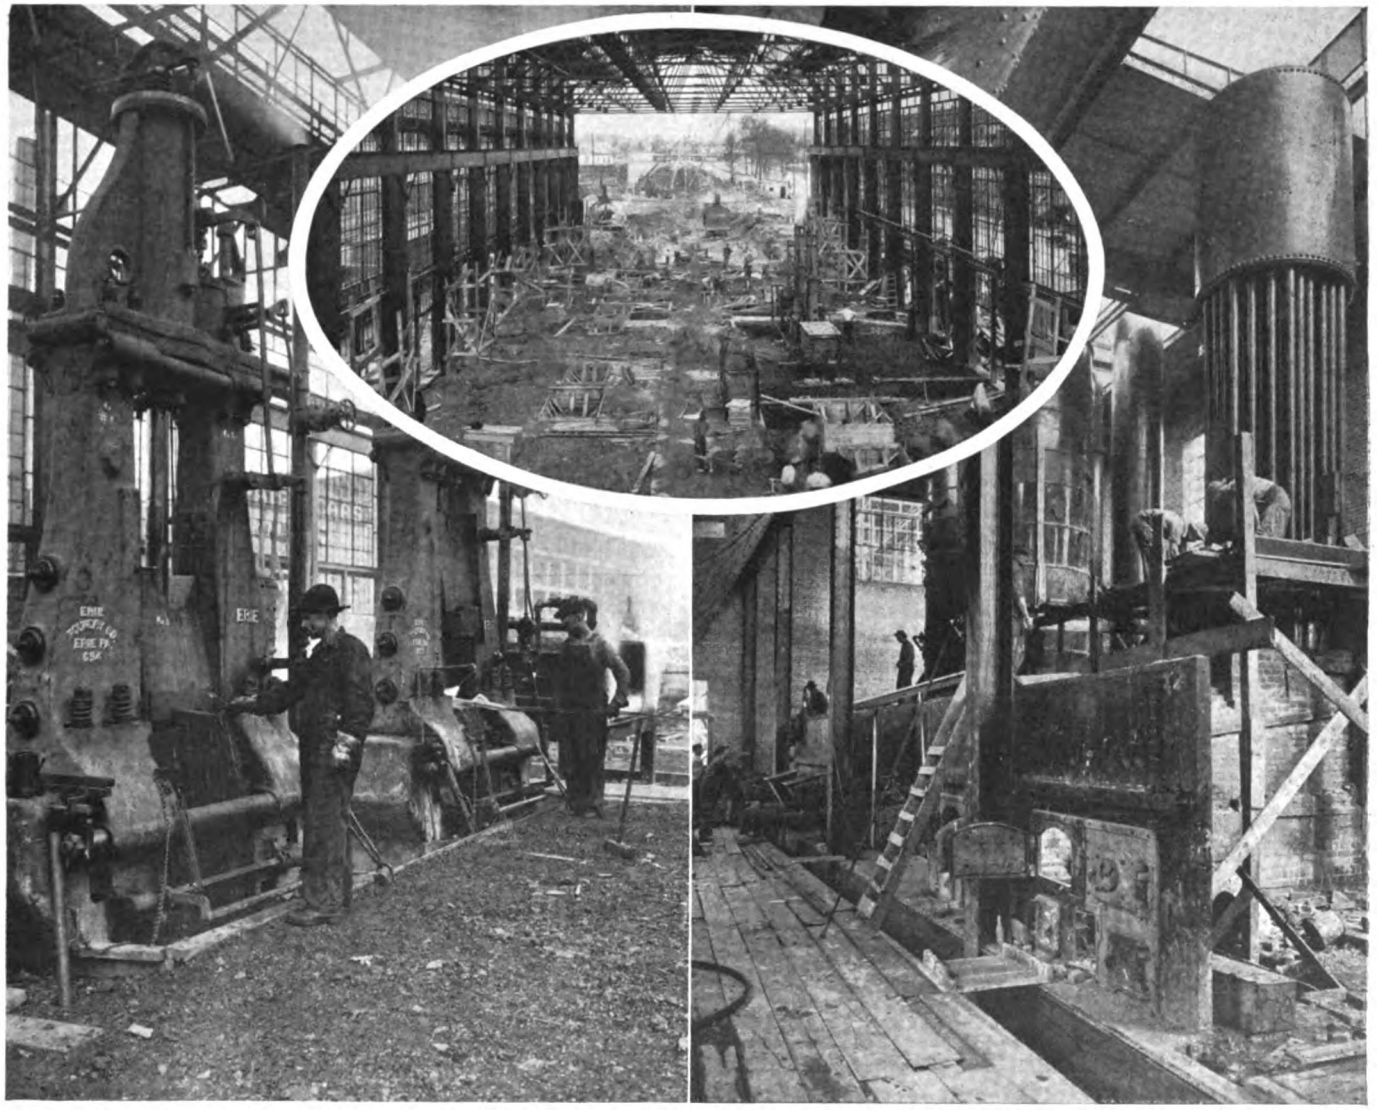
Spiral bevel driving gears are fitted to the rear axle which is of the one-bearing floating construction. There is a Hyatt roller bearing at each wheel, and the differential unit is carried on Hyatts, with New Departure ball thrust bearings at either side and ahead of the driving pinion. The axle housing is a strongly proportioned steel pressing, having a large plate at the rear for access to the differential.

As in other Oaklands, this car has the form of frame in which the channel is made quite deep to meet the running board brackets. No apron is used between frame and running boards, the sides of the frame acting in that capacity. This does away with one extra part and makes a simple construction. The frame tapers practically its entire length, being quite narrow at the front to give a good turning radius. The characteristic Oakland rocker bearings for the mounting of the brake equalizer and the control levers and brake pedal connection are used.

Body construction is light by the use of a wood framework and steel sheets. Fenders are crowned, and the standard body color is a coach green.

It goes without saying that the equipment of this latest addition to the Oakland range of models is entirely in keeping with the character of the car as a whole.

Building the Timken-Detroit Axle Co.'s New Drop Forge Plant



Detroit, Mich., Oct. 23—The new drop forge plant which is now being built across Clark Avenue from the main plant of the Timken-Detroit Axle Co. will be about 558 ft. long, 70 ft. wide, and 50 ft. high. It is of steel construction, the sides from the ground up on both sides being of glass set in steel frames.

In the new drop forge will be thirty-three hammers ranging in size from 1500 lb. to 8 tons. They are all set on a concrete base and a bed of wooden spiles to eliminate as much of the jar as possible.

Three self-stoking Wicks boilers generating 1200 hp. will supply the power for these hammers. The exhaust steam will be used in a turbine motor to generate electricity for use in the drop forge. Running the full length of the drop forge on the inside will be a 40-ton traveling crane to carry the dies from the die room to the hammers, and to carry raw forgings to and from the hammers throughout the shop. Out in the stock yard, which runs the entire length of the building, is another 5-ton magnetic traveling crane which will unload the freight cars and move stock around in the yard up to the door of the drop forge where the 40-ton crane will pick it up.

In the die room will be another smaller crane to move the dies to and from the forge shop.

All of the steam pipes and power pipes going from the boilers to the steam hammers will be contained in a tunnel running through the center of the shop, thereby eliminating all piping over the hammers. The exhaust steam from the hammers will be carried back to the engine room by the way of this same tunnel. There is also a tunnel running from the drop forge under Clark Avenue to the main plant so that the truckers carrying stock back and forth will not have to go out of the buildings.

The FORVM

ARGUING BALANCE. THE SIX AND THE TWIN SIX DISCUSSED FROM DIFFERENT VIEWPOINTS OF THEORY

Fallacy in Twelve Argument — Six Balance Better Than Allowed

By David Fergusson
Mechanical Engineer Pierce-Arrow Motor Car Co.

EDITOR THE AUTOMOBILE:—There have been many articles published during the past few months on the twelve-cylinder engine; in all these there is generally found the statement that in the twelve V-type engine with six cylinders on each side, 60 deg. apart, the force due to the inertia of the reciprocating parts, which is recognized as being of tremendous moment, is only half that of a six-cylinder engine of the same total cylinder volume.

In some of these articles, a direct comparison has been made between a six-cylinder 4 by 5½-in. engine and a twelve-cylinder 3 by 5-in. engine, the total cylinder volume of each being practically alike. In this case the smaller piston, together with the reciprocating part of the connecting-rod, weighs about one-half of the corresponding parts of the larger piston. It is then assumed that the twelve-cylinder engine is merely two sixes and that the inertia loads present in the twelve-cylinder type of engine are those due to one piston complete, with the small end of one connecting-rod. I have been waiting for someone to point out the fallacy of these assumptions, and as no one has done so, I feel impelled to myself bring the following to your readers' attention.

There is, in my opinion, considerable misunderstanding in regard to the stresses in the conventional twelve-cylinder, V-type engine. This should be considered not as two six-cylinder engines, but as a twelve with all cylinders vertically in line. This alters the case entirely, and gives a much more correct impression of the loads that must be provided for. We then find that the inertia of the reciprocating parts to be considered is not that of one piston and the part weight of one connecting-rod, but it is double this, as two connecting-rods and two pistons are attached to one crankpin. Two pistons 3 in. diameter complete, with the reciprocating parts of two connecting-rods, weigh at least as much as one 4-in. diameter piston complete with the reciprocating part of its connecting-rod. Therefore, the inertia load in the case of the twelve is as great as in the large diameter six and, therefore, necessitates as large a diameter crankshaft, and this shaft must, in addition, be very much larger in diameter in the case of a three-bearing crankshaft than is necessary in a seven-bearing shaft.

It will be contended that the assumption of all the twelve cylinders being in line is not a fact, as the six cylinders a side are placed at an angle of 60 deg., this certainly reduces the resultant inertia loads, but only about 18 per cent. It is, therefore, much safer to consider this in the manner indicated, especially as twelve cylinder engines are being run at a higher speed. The combined inertia force at high speeds being greater than the explosive force, it is quite possible that the twist of the crankshaft, due to the force created by the inertia of the reciprocating parts, may be almost as great in the twelve cylinder engine as in the six, in which case the vibration coming from a torsional twist of the crankshaft should be almost as great in the twelve-cylinder crankshaft, as in the six, if the same diameter shaft is used in both cases.

Twin Six Balance Superior

By J. G. Vincent
Vice-President of Engineering, Packard Motor Car Co.

EDITOR THE AUTOMOBILE:—I have read with interest the proof sheet of Mr. Fergusson's remarks regarding articles recently published on the twin six or twelve-cylinder engine. I would like to comment on the points that he has raised, as follows:

Mr. Fergusson refers to a direct comparison that has been made between a six-cylinder engine, 4 by 5½ and a twin six engine, 3 by 5, and as these are the sizes of engines referred to in my paper before the Detroit Section of the Society of Automobile Engineers on Sept. 16, and before the Indiana Section of the Society of Automobile Engineers on Sept. 24, my comparisons are, perhaps, the ones referred to.

In the first place I must disagree with Mr. Fergusson regarding the relative weight of 3-in. and 4-in. pistons, as, from my personal experience, I am convinced that it is not possible to make a 4-in. piston assembly complete with piston rings, piston pin, piston pin set screw and cotter pin that will not weigh more than twice as much as a 3-in. piston assembly of corresponding design. In my paper before the Society of Automobile Engineers, I included the following figures regarding reciprocating and rotating weights and their inertia effect, which were taken from three actual motors:

	338 Six, Lb.	Special 338 Six, Lb.	Twin Six, Lb.
Piston assembly, complete with rings, piston pin and set screw	4.125	2.11	0.814
Connecting-rod upper end	1.38	0.828	0.625
Connecting-rod lower end	3.31	2.421	1.52

The following table gives a comparison of forces due to gas pressure and inertia at 2000 r.p.m. of the same motors:

Inertia of one piston assembly complete	2,130	1,140	492
Centrifugal forces of one connecting-rod lower end	1,030	754	430
Centrifugal forces of one pair of connecting-rod lower ends	....	....	860
Crankpin bearing pressure per square inch due to inertia	768	433	379
Crankpin bearing pressure per square inch due to gas pressure	916	916	871

The column of figures under 338 Six was taken from one of our last year's standard six-cylinder motors. The column of figures under Special 38 Six was taken from a motor of substantially the same design as last year's 38, but with reproportioned length of crankshaft bearings, the lightest possible connecting-rods, machined all over, and equipped with special alloy pistons. The column of figures under Twin Six was, of course, taken from one of our standard engines.

As suggested by Mr. Fergusson it is, of course, correct to

add the upper end of the connecting-rod to the piston assembly to get the total reciprocating weight for each cylinder. By this process we get the following information from the figures on the previous page:

Total reciprocating weight of 338 6-cylinder motor.....5.505 lb.
Total reciprocating weight of special 38 6-cylinder motor...2.938 lb.
Total reciprocating weight of twin six motor.....1.439 lb.

Now in regard to Mr. Fergusson's suggestion to consider the twin six as having twelve vertical cylinders, I certainly must take exception to this method of treating the subject, as all my arguments have been based on the V-type or twin six motors and not twelve-cylinder vertical motors. It is true that the inertia forces of a twelve-cylinder motor overlap, as suggested by Mr. Fergusson, and his statement that the net inertia effect is only approximately 18 per cent less than it would be in a single six-cylinder vertical engine, whose reciprocating parts weighed twice as much as the twin six, is approximately correct. Figures from actual parts, however, throw considerable light on this subject.

Let us see how this works out in actual practice, taking Mr. Fergusson's method of figuring:

As outlined above, the reciprocating parts in a single cylinder of a Packard twin six motor, 3 by 5, weigh 1.439 lb. and two complete sets of reciprocating parts, therefore, weigh 2.878 lb. Deducting 18 per cent from this weight, leaves a net weight of 2.36 lb. as the figure to be used in computing the combined inertia effect of the two sets of pistons and rod upper ends in the twin six motor.

As outlined above, one piston assembly and rod upper end of the 3-38 motor weighed 5.505 lb. or considerably more than twice the equivalent weight of 2.36 lb. for two sets of reciprocating parts of the twin six.

As mentioned in my paper before the Society, it might be argued that this is not a fair comparison. My reason for giving these weights is to show what has been considered good practice in six-cylinder motors of approximately 4 in. bore by 5½-in. stroke. It was for the purpose of putting this argument on a strictly engineering basis that I included the figures for the special 38 motor which I believe to have been equipped with reciprocating parts as light as it is possible to make them, and probably slightly lighter than can be produced in actual manufacture. By using reciprocating parts of this special motor for comparison, we obtain a figure of 2.938 lb. to be used in direct comparison with the net figure of 2.36 lb. of the twin six, or a difference of 0.578 lb. in favor of the twin six construction.

By calculating the inertia effect at 2000 r.p.m. for the twin six motor, and for this special 3-in. by 5½-in. six-cylinder motor, we obtain a figure of 670 lb. for the twin six, and 918 lb. for the special six, or 248 lb. in favor of the twin six construction.

The corresponding inertia effect of the 3-38 motor, which I maintain has been considered good six-cylinder practice, amounts to 1712 lb. or 1042 lb. in excess of the twin six construction.

Effect of Speed

Now, as to Mr. Fergusson's suggestion that something ought to be figured in on account of the twin six motor being run at higher speed, I wish to state that I do not consider this proper engineering, because the two motors should be compared at the same motor speeds. My reason for making this statement is that the twin six type of motor will develop more power than the single six-cylinder motor of the same piston displacement, at the same motor speed, and this being the case, it would actually be necessary to run the twin six motor at a lower speed than the single six, in order to have it only develop the same amount of power.

The fact, however, that the inertia forces are less in the twin six motor, makes it possible to run it at higher speeds and thus obtain larger range of ability without undue bearing pressure due to or arising from the forces of inertia.

I have carefully noted what Mr. Fergusson has to say about crankshaft design. A great many things must be taken into consideration when designing a crankshaft, particularly its length, and the magnitude of the power impulses as well as the forces due to inertia. I have proved by exhaustive experiments that there is considerable advantage in the three-bearing shaft over the seven-bearing type, providing the motor is short enough overall to permit of proper strength in the design to resist the bending forces. I would like to outline what I consider to be the main advantages of the three-bearing shaft, as follows:

First: The main bearing portions of a crankshaft are, of course, its weakest points, so far as resisting torsional displacement is concerned, and the more main bearings it is found necessary to use, the longer this section of the shaft will be, and its ability to resist torsional displacement will be correspondingly reduced.

Second: I have found from actual experience, that a single long bearing is much better than two short bearings of the same total length, partly on account of the extra loss of fillets in the two short bearings, but primarily on account of the fact that there is not the same tendency for the oil to work out of the long bearing, as it has to travel twice as far before actually getting out of the bearing.

Third: A proper balance between the forces due to inertia, and the forces due to the power impulses is much easier to obtain in a three-bearing shaft for the following reasons: The center bearing of either a single or twin six motor is the one that is apt to have the highest bearing pressures, unless the designing work is very carefully done. In a seven-bearing shaft it is, I believe, correct to assume that the pressure due to each working stroke is equally distributed over two main bearings; that is, the pressure, due to the working stroke of piston No. 3 will be distributed over main bearings, Nos. 3 and 4, and assuming that with this design these bearings are properly designed to carry this load, we will obtain comparatively short bearings, or, in other words, approximately the length of main bearings that has been common practice in seven-bearing shafts.

If we take these bearings as a basis, and then consider the bearing pressures due to inertia, we will discover that the center bearing pressure will run excessively high, as in this design one-half of the inertia effect of rods and pistons in both cylinders 3 and 4, must be considered as concentrated on the center bearing.

If a seven-bearing shaft is to be designed to have its bearing pressures properly equalized, it will be found necessary to make the center main bearing something like twice as long as the other intermediate main bearings, and this is usually found impossible, on account of the excessive length that will result.

In a three-bearing shaft there are but eight cheeks, while in a seven-bearing shaft there are twelve cheeks, and all other things being equal, it is, of course, true that the total main bearing length of a seven-bearing shaft is cut down by the total width of the four additional cheeks, or else the motor will have to be made correspondingly longer, and this loss in bearing length, coupled with the loss of bearing efficiency, due to the difficulty of keeping oil in the several short bearings, certainly works to the disadvantage of the seven-bearing shaft.

So far as the inertia forces are concerned, the three-bearing shaft is, therefore, the best, and it is only necessary to use more bearings when the crankshaft has to be so long that it would bend under the influence of the power strokes.

One of the most attractive features of the twin six construction is the fact that, due to the small magnitude of the separate impulses and the short compact form of motor on account of its small bore, it is possible to use an ideal design of the six-cylinder, three-bearing crankshaft.

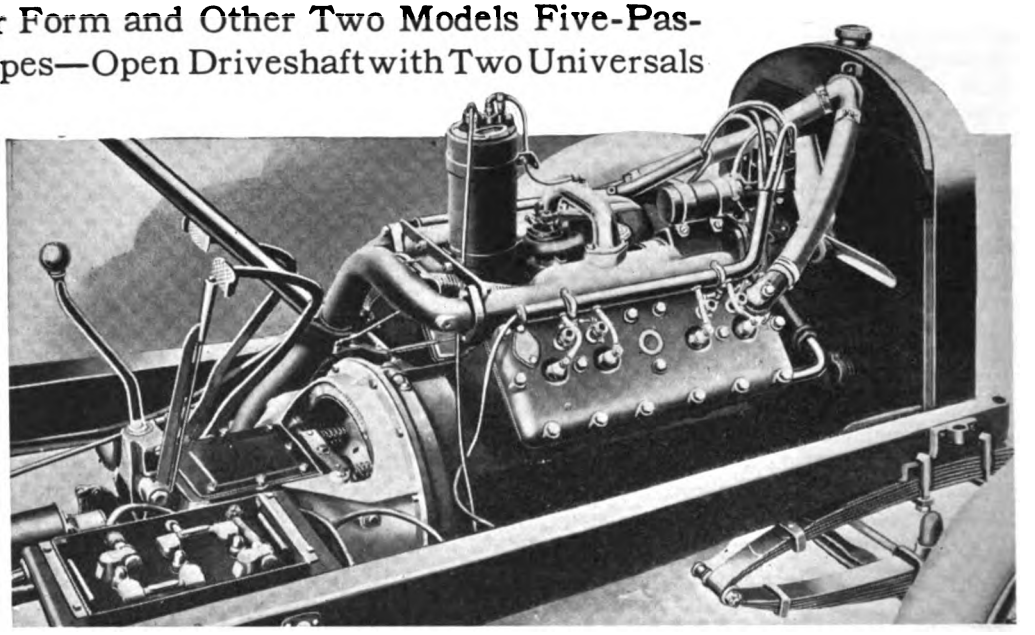
Two Jackson Eights and a Four

Elliptic Springs All Around—Large Eight in Seven-Passenger Form and Other Two Models Five-Passenger Types—Open Driveshaft with Two Universals

THE Jackson Automobile Co., Jackson, Mich., has an ambitious program for the coming year and is the first manufacturer to announce two eights of different capacity. Both will have Northway motors, the larger the engine which was introduced last winter and the smaller a new motor modeled upon the same general design. In addition there will be a light four with a high-speed type of engine and it is expected that this will be a very popular car.

The light four is a Northway motor like the eights, having dimensions 3½ by 5 in. —192 cu. in.—and, being carefully balanced, its ability for high-speed running can be made use of freely. It is the idea of the Jackson company that there will be a large demand for a thoroughly good and well finished four-cylinder car despite the low prices of some sixes and eights, so it is making an excellent job of its four which is listed at $985.

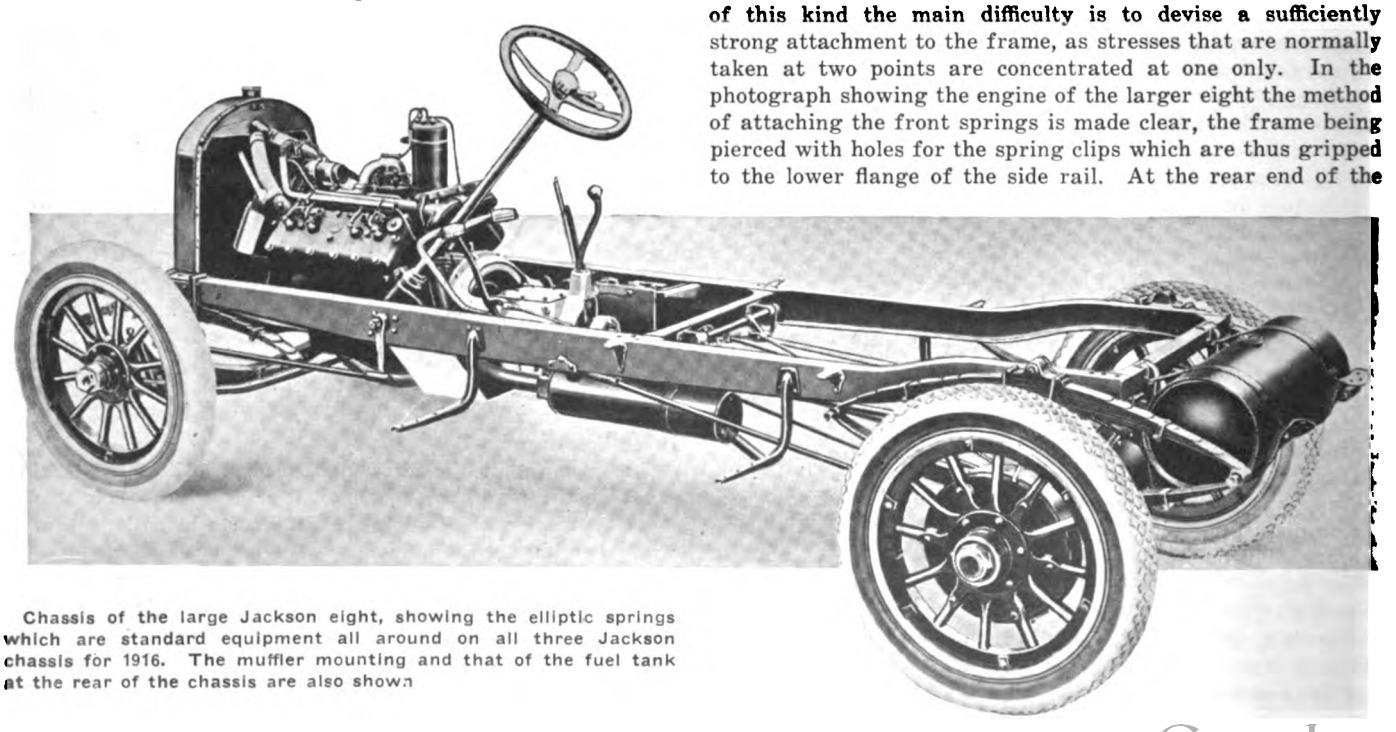
The smaller of the eights has 2⅞ by 4¾ bore and stroke, or 246.7 cu. in. and the larger 3½ by 4½ in., giving a piston displacement of 346.3 cu. in., the prices being $1,195 for the smaller and $1,685 for the larger car. Only the large eight has a seven-passenger capacity, the other two being supplied with five-passenger touring bodies. A feature common to all three cars is high finish for the bodies and the use of really good leather upholstery. Also the Jackson company is to be congratulated on having broken away from the conventional black paintwork, as the four is finished in a rich maroon tint, the small eight in dark green with natural wood wheels, and the large eight in dark blue.



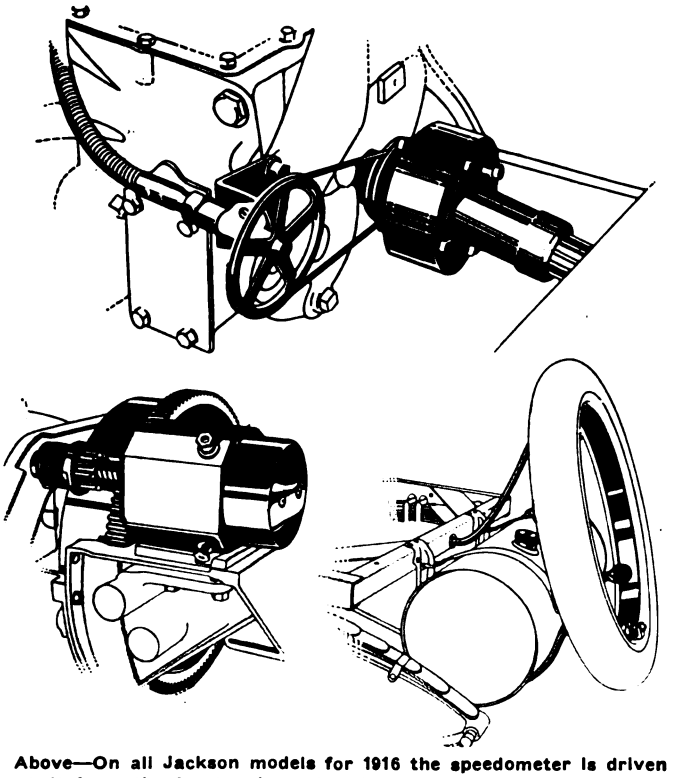
Northway eight power plant used in the large Jackson eight-cylinder model for 1916. Note the vacuum fuel feed tank and the single exhaust manifold

Elliptic Springs Employed

On all Jackson chassis both front and rear springs are full elliptic, giving an unusual amplitude of motion and ability to take really bad roads in comfort. In using springs of this kind the main difficulty is to devise a sufficiently strong attachment to the frame, as stresses that are normally taken at two points are concentrated at one only. In the photograph showing the engine of the larger eight the method of attaching the front springs is made clear, the frame being pierced with holes for the spring clips which are thus gripped to the lower flange of the side rail. At the rear end of the



Chassis of the large Jackson eight, showing the elliptic springs which are standard equipment all around on all three Jackson chassis for 1916. The muffler mounting and that of the fuel tank at the rear of the chassis are also shown



Above—On all Jackson models for 1916 the speedometer is driven by belt from the front universal. Note the splined telescope slide mounting for the universal

Below at left—How the starting motor is mounted at the flywheel

Below at right—Rear spring attachment and mounting of spare tire carrier. Note the round gasoline tank for maximum strength with minimum liability to leak

frame the other springs are attached in the same manner except on the large eight where a swivel mounting is used.

The largest car has both torque and radius rods, so as to relieve the springs of all stresses save those imposed by the load, but the two smaller chassis have only torque stays, driving effort passing through the springs. In practice it seems that this gives a very easy and elastic drive, the flexibility of the spring acting as a cushion.

Not long ago the Jackson company was using a single universal with the propeller shaft inclosed, on some of their models, but this design has now been abandoned in favor of the open type shaft with a universal at each end. The rear axles are all floating and the gear ratios on high are 4.4 to 1 on the four and small eight, and 4.25 to 1 for the large eight. It should be mentioned that telescopic motion of the drive shaft is cared for by mounting the front universal upon a large splined shaft, which eliminates a universal combining sliding with the other motion. This makes for easy inclosure and better lubrication of the joints.

Autolite Electric Equipment

On all models the two unit Autolite system is used, the distributer being combined with the generator. The starting motor is carried low on the crankcase side, and the generator is between the cylinders on the eights, being mounted in the usual place on the four. Fuel is supplied by a Stewart vacuum tank sucking from a rear tank which is made of round section so as to give the greatest possible strength and minimum of liability to leakage.

The Power Plants

Returning to the power plants, each of these includes a cone clutch with external springs and a three-speed gearset, and both the eights are of the same sort of design having the crankcase divided vertically, the cylinder blocks being cast integral with half the case. The large motor is practically unchanged since the Northway company first introduced it early in the present year and the small one is different only by the fact that it has a two-bearing crankshaft instead of the three bearings used for the larger engine. Both have pressure lubrication of a most complete kind and a single camshaft with sixteen cams. The same style of forked connecting-rod is used for both motors, this having proved extremely satisfactory in the large number of Northway eights that have been put in the hands of private users during the last six months. The cylinder heads are detachable, which makes a light task of the occasional necessity for cleaning out carbon, and the spark plugs are located centrally which is usually assumed to be the most efficient position.

Wide Steering Lock

The Jackson company makes a feature of its wide steering lock which makes the car convenient to handle in cities or in exceptionally rough country. To enable the fullest value of this to be obtained the wheelbases have been kept fairly short, that of the four and small eight being 112 in. and that of the large eight 124 in. Tires are 32 by 4 all round on the smaller chassis and 34 by 4½ on the big eight.

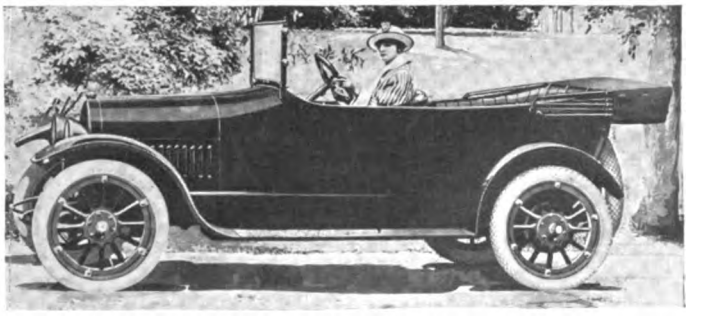
Runabout bodies are supplied instead of the five-passenger equipment, on the four and the small eight, but the large eight will be made with a seven-passenger touring body only. The runabout type is very good in both appearance and comfort and has a most capacious boot, or rear storage space, which is always extremely useful for touring. It should be remembered that the Jackson company also can provide its special Transcontinental body, in which the seat back of the front compartment can be let down and a comfortable bed made with the upholstery and cushions. This body has met with a considerable success since its introduction a few months ago and it is surprising that the type is not more common, considering the popularity of camping on tours.

—

A Good Book for Draftsmen

To books intended to assist the young draftsman there are no end, but one of the best and clearest is the latest addition, published by G. P. Putnam's Sons, New York, and The Cambridge University Press, England. The author is John Handsley Dales, former head of the engineering department of Bradford (England) Technical College. Commencing with instructions on such simple yet elusive things as the proper method for sharpening a pencil, the book continues with a series of drawing exercises designed to train hand and eye in the manipulation of all the tools of the draftsman's trade.

No questions of machine design are considered, the book's sole purpose being to teach drawing and it should be of very real assistance in developing combined speed and accuracy. Perhaps it is rather a college primer than a factory library volume, but there are few juniors in automobile drafting rooms who would not be benefited by a careful perusal of the volume and by some practice with the exercises. The title, Mechanical Drawing (Dales), does not give much idea of the usefulness of the book.



The small eight-cylinder Jackson with the new body

The Rostrum

Flying Paper Dangerous on Speedways

EDITOR THE AUTOMOBILE:—In the interest of fair play and best results in speedway contests, it would seem only fair to recommend that some action be taken in future contests to have men stationed around the track to remove scrap papers which—through one cause or another, may get onto the track.

The writer noticed two laps before entry No. 2, Peugeot, driven by John Atkin withdrew from the race with a cracked cylinder, that his radiator was almost entirely blanketed by a sheet of paper picked up on the track, and without any doubt this had a very considerable bearing on the withdrawal of this car. The writer also noticed that there was a great amount of loose paper, particularly on the bank track at the right of the grandstand, which paper was in a state of constant motion as the cars passed through it.

In view of the results of the race, it is very improbable that had the paper not been on the track the results achieved by the winners would have been any different, but it leaves in the mind of the spectator a possible doubt as it allows an element of luck, which should not be present, to enter into the final result of the race.

We thoroughly believe that American built cars can repeat or even better the records made, and we wish to accomplish this result without a shadow of doubt as to the conditions. H. R. S.

Schenectady, N. Y.

Probable Effect of Lighter Flywheel

Editor THE AUTOMOBILE:—What would be the result of putting a smaller flywheel on an automobile engine? Would it make a faster easier-pulling engine where used in a stripped car weighing say about half as much as the touring car in which the engine is used? My idea is to use the flywheel of a 4 by 4 motor on a 4½ in. by 5 motor. Both motors are identical except as to size and also size of the cars they were used in. Both are the same make and same year model.

Would you advise using the lighter flywheel for the cut-down car?

Columbia, S. C. C. M. L.

—It is not advisable to put a lighter flywheel on a motor unless it is to be used for high speed work only. The lighter the flywheel the more unevenly a motor runs at low speed and this is quite noticeable in a car used for ordinary work. On racing cars, however, where most of the traveling is at very high speed a much lighter flywheel can be used than in the case of touring cars. Therefore, unless you intend using the car for only high-speed work it would be advisable to keep the standard size flywheel.

Applying Stewart Vacuum to Cadillac

Editor THE AUTOMOBILE:—Can you please tell me if a Stewart vacuum gasoline system can be successfully installed on a 1915 Cadillac eight touring car, and if it can be installed, will you kindly publish instructions how to do it?

Bangor, Me. F. H. C.

—The Stewart vacuum system can be installed on a Cadillac eight, the model 113-K being the best for the installation. The instructions for installing are as follows:

Place the tank on engine side of dash, right hand side of car, as high as possible.

Use 4⅝ in. wheel gear spacers under the bracket. This will permit setting the bracket out from dash far enough to clear a pipe that will otherwise obstruct.

Move both brackets on the tank as close together as possible.

Tap the neck of the carbureter above the butterfly valve instead of tapping the manifold, which is water-jacketed.

Five Cylinders Hard to Balance

Editor THE AUTOMOBILE:—Why is it that automobile manufacturers never build a five-cylinder motor? In a five-cylinder, four-cycle motor, there would be a continuous turning effort of the crankshaft, due to the overlapping strokes, the one added cylinder being sufficient to cover the interval of "no power" which is present in the four-cylinder type of automobile engine.

A five-cylinder motor has the least number of cylinders to have continuous power and therefore seems to me should have been the next step after the four.

Since the greater number of cylinders creates the greatest smoothness, it is evident that absolute smoothness can never be attained, no matter how many cylinders are used. For this reason, the most practical motor in my judgment would be a five, as it has the least number of cylinders to give continuous power. K. B. W.

E. Orange, N. J.

—A five-cylinder engine is only in proper balance when the cylinders are arranged star fashion as in some aeroplane motors. This means that a vertical cylinder motor with five cylinders would vibrate a good deal. It would not run smoothly like a six. Vibration has nothing to do with the overlap of power impulses and it is freedom from vibration more than the even torque which accounts for the great popularity of the six.

Ford Direct Ratio 3.63 to 1

Editor THE AUTOMOBILE:—Am asking the following questions with the idea of using Ford axles in the construction of a light car, roadster model for three passengers, using the conventional type of frame and cantilever rear springs and semi-elliptic front springs.

1—Please advise if a Ford rear axle will support a three-, or four-passenger car of about 1900 lb., using spring seats on the axle housing about 32 in. between centers.

2—Give the ratio of driving gears.

3—Will the rear axle stand a four-cylinder, high-speed motor 3¼ by 5, developing about 18 hp. at 1000 r.p.m.?

4—Suggest a method and give a sketch of attaching semi-elliptic springs to the Ford front axle about 27 in. center.

5—Give dimensions of shaft required to fit transmission end of universal joint, also dimensions of propeller shaft end.

Owensboro, Ky. F. S. B.

—The Ford rear axle should be able to support the load you mention.

2—The ratio of the rear axle driving gear is 3.63 to 1.

3—The rear axle is capable of transmitting 18 hp.

4—This is a straight job and merely consists in having the necessary fittings made to fit the frame and axle.

5—A sketch is given in Fig. 1, which will give the dimensions of the part which you need.

Testing Spark Plugs and Cylinders

Editor THE AUTOMOBILE:—Kindly give me the different methods for testing the effectual working of the spark plugs in giving equal and uniform explosions, if there is any variation owing to the strength or power of the spark.

2—Likewise kindly give the different methods for testing out the efficiency of each cylinder for suction of the carbureted gasoline into it and for non-leakage of the gas from the explosion therein.

3—When the engine refuses to respond or chokes down on too sudden and too wide opening of the throttle, kindly explain the causes therefor, i.e., whether from too lean a mixture, or an over-rich mixture, or defective suction of part or all of the cylinders, or whatever they may be.

Connersville, Ind. H. L. F.

—The operation of the spark plug can be readily determined by eye. All that it is necessary to do is to place the spark plug points at the proper distance apart which is between 1/64 and 1/32 in. for magneto use and then after this approximate adjustment is made, remove the plug from the cylinder and start the engine on the other three. The color and intensity of the spark which jumps across the gap of the plug removed from the cylinder gives a ready clue to its performance when firing a charge. The spark may vary all the way from a thin, fine line to a thick dot of flame. Something between the two, or a hot, blue spark, is most desired.

2—The best method for testing the suction of each of the cylinders is by compression. Cylinders, roughly speaking, having the same compression will have the same suction.

3—The choking action you speak of is generally due to too rich a mixture. Properly designed motors, unless improperly timed, do not suffer from defective suction.

Oxygen for Removing Carbon

Editor THE AUTOMOBILE:—I have a 1915 eight-cylinder Cadillac. How far should this car be run before the carbon is cleaned out?

2—I expect to have an expert do this. What is the best method?

3—The gear ratio is 4 7/16 to 1. I get about 10 and 11 miles to the gallon. If this were changed to 5 to 1, can you tell me what I would get to the gallon of gasoline then?

4—What is the best speed that this car will develop as it is with full equipment?

5—Does it harm the engine to run it at 60 m.p.h.?

New York City. J. C. W.

—The frequency with which carbon should be removed from a motor depends upon its steady rate of accumulation. For instance, a motor considerably carbonized one day might have this carbon almost entirely burned out by driving the car at an extremely high rate of speed for a certain time. On the contrary, if the car was not subjected to this extremely high rate of speed, the accumulation of carbon would be constant. The rate of this constant accumulation depends upon the nature of the oil used, the amount of oil used, as well as the carbureter adjustment. If the oiling system is in improper adjustment so that an excessive amount of lubricant is being used, and if after such a time the mixture happens to be too rich, the condensation of this lubricant would form a sticky film to which lamp black from the very rich mixture would readily adhere. Again, certain grades of lubricants have a larger carbon residue than other lubricants, and as any lubricant which finds its way to the combustion chamber will burn under the high temperatures reached, the greater this carbon residue in the oil, the greater will be the amount of carbon deposit. Frequency with which carbon should be removed from a motor depends upon the rate of its accumulation which may, to a certain degree, be controlled by the operator. The instruction book which is shipped with every car from this factory takes up the matter of carbureter adjustment and the nature of lubricants which should be used on Cadillac cars very carefully.

2—When necessary, carbon may be very successfully removed by the oxygen process. When using this process, however, the piston should be on its high dead center, in order to permit the head of the piston to be thoroughly burned over, and at this time both valves in the cylinder should be closed to prevent the possibility of the flame passing through the inlet valve to the carbureter, and as a further precaution the carbureter should be drained.

3—The gear ratio on this particular car is 4 7/16 to 1 and the mileage is from 10 to 11 miles to the gallon of gasoline. As to the effect on the fuel consumption should the ratio be changed to a 5 to 1, this would depend somewhat upon the nature of the country. Ordinarily, of course, changing from a 4 7/16 to 1 to a 5 to 1 means that for any particular road the engine would be operating at a higher revolution per minute, and a higher rate of fuel consumption might be expected. However, if this car happened to be operated in a hilly country, it is possible that by changing from a 4 7/16 to 1 to a 5 to 1 the fuel consumption might be actually decreased, for the reason that with a high gear, hills would have to be negotiated with a wide-open throttle, whereas with a low gear the same grades might be negotiated readily with the throttle partially closed.

4—The maximum speed would depend upon the type of the body, whether a two-passenger, a seven-passenger or a closed type. The gear ratio, size of the tires and whether the windshield were both up or down, would also enter into this question. A complaint was received recently from an owner because his standard type 51 car would not do better than 70 m.p.h. but you probably won't want that speed.

5—The engine speed at a road speed of 60 m.p.h. depends of course upon the gear ratio. If an engine is being run under load, its tendency toward self injury will be less during this period than with the motor run idle for the same length of time at the same high rate of speed. The motor should never be run idle at high engine speeds. If, however, all parts of the car are in proper adjustment; the cooling and oiling systems in proper working condition; the bearings properly adjusted, etc., there is no reason why the usual operation of this car from its lowest to its highest speed, under the proper conditions, should be in any way detrimental or result in any other than the ordinary wear.

Bijur Electrical Units Standardized

Simpler and Lighter Construction— Magnet Shells Cut from Steel Tube

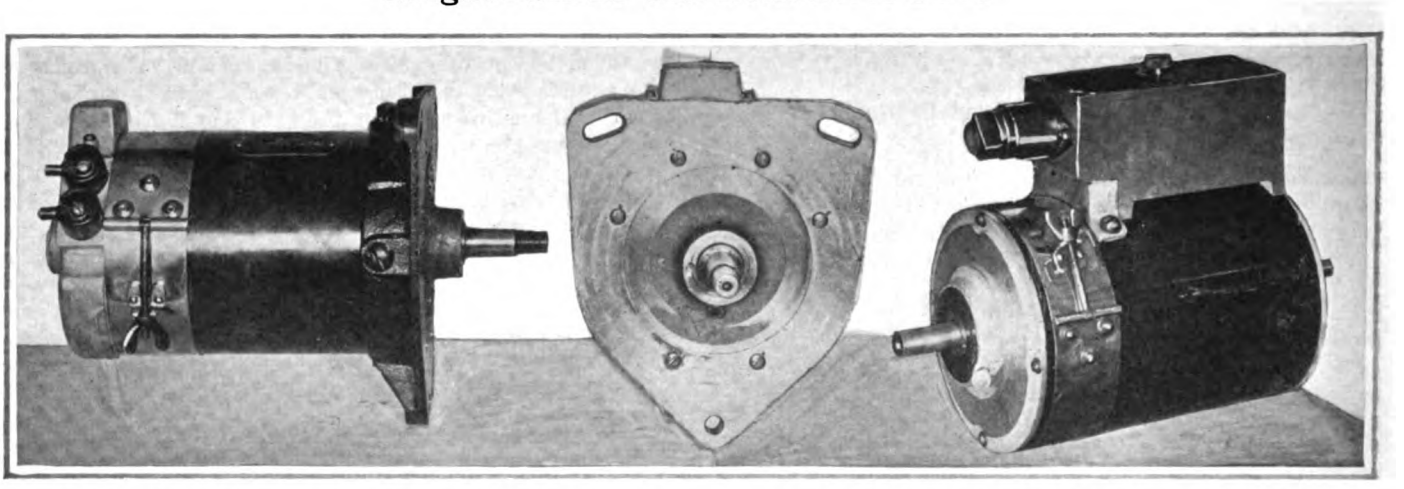

Fig. 1—Left—Constant current generator controlled by third brush principle. Center—Generator base, showing slotted bolt holes for chain adjustment. Right—Voltage-regulated type of generator with detachable regulator on top

INCREASED efficiency in conjunction with a marked reduction in the size and weight of the principal units marks the development of electrical equipments for automobiles during the past two years. Compactness is a fundamental requirement and this has led to the cutting down of much metal in generator and motor construction, especially in regard to the magnet, though there has also been much weight saving in the more efficient and compact methods of arranging the windings. With this desire for compactness has come the necessity for ease of manufacture in order to keep the production cost inside the competitive field.

After more than three years' experience the Bijur Motor Lighting Co., Hoboken, N. J., has decided that the above requirements are best obtained by the adoption of a simple cylindrical form for the field magnet casing with four inserted poles. For 1916, therefore, the Bijur output will consist of motors and generators constructionally identical, with the exception of the windings and size. All magnets are cut from seamless steel tube. All are four-polar with drop-forged poles screwed in after inserting the windings. The motors are designed for flywheel connection only either by direct sliding pinion or through reduction gear and sliding pinion. The Bijur company, however, does not supply gearing.

The generators are divided into two classes, irrespective of size, namely, the constant-current type in which the output is governed inside the generator by means of the third brush principle, and the voltage-regulated type in which a special vibrating regulator of Bijur design is mounted on top of the generator casing holding the voltage by the use of a resistance inserted in the shunt field.

Besides the separate motor and generator there is a motor-generator set for connection by chain to the engine. This design is remarkably simple and is suited to the needs of the smaller sizes of power plant.

The constant current type of generator has the great advantage of simplicity, all the control being located inside the generator casing. The third brush principle is used, in which the speed of the armature controls the amount of current passing through the shunt coils by field distortion. The outfits can be classified as follows:

A Constant current generator Geared motor
B Constant current generator Direct acting motor
C Voltage regulated generator Geared motor
D Voltage regulated generator Direct acting motor
E Motor generator

Vibrating Reed Regulator

The voltage-regulated generator is governed by a vibrating regulator, which is made only in one size for mounting on the magnet casing. This regulator differs from others of similar type in the arrangement of the contact points, Fig. 2, which are fitted to the ends of brass reeds so as to preserve a clean contact surface at all time by varying the actual point at which the spark occurs. The coil is arranged vertically with the hinged iron armature above. Behind the hinge on an extension of the armature one of the two reeds R1 is fitted, while the other reed R2, representing the fixed point is arranged horizontally so that the weights at the ends, in which the platinum points are inserted, face one another. An adjustable spring which holds the armature away from the core is provided. When attraction of the armature takes place as the speed of the generator rises, the contact points are separated. This inserts a resistance connected across the contacts, Fig. 3, in the shunt field, thereby cutting down the power of the field magnet. The spring then returns the armature and again closes the points, allowing the shunt field full current on which the action is repeated. On high speeds this armature vibrates at a fast rate and the claim is made for the special reed arrangement that the contact points cannot become pitted owing to the sideways vibration of the surfaces.

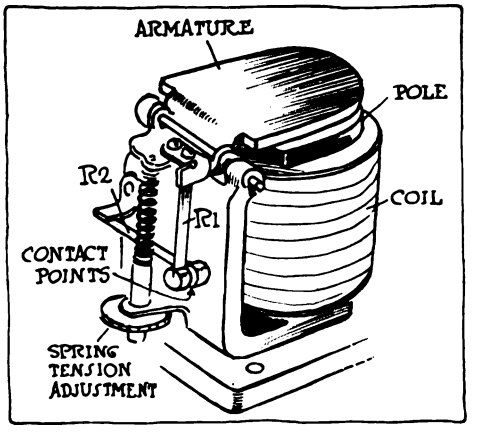

Fig. 2—Bijur voltage regulator in which the contact points are fitted to two vibrating reeds to preserve a good surface

In the same rectangular aluminum casing, Fig. 4, the cut-out *C* is fitted and all the connections to the generator are made by plugs *P*, which are inserted into sockets in the generator casing. No electrical knowledge is required in changing the regulator. The act of putting it in place on the generator and fastening it by the single thumb nut automatically makes all necessary connections through the plugs.

This feature is of great value in the case of a breakdown or failure on the part of the regulator. All the owner does is to remove it, forward it to the maker and replace with a new one. By this arrangement the maker can seal up the regulator, and repair according to guarantee only when the seals are unbroken. The connection to the outer circuit is made through a two-point plug *T*, which is inserted into a socket *S*, in the end of the regulator casing.

Chain Adjustment Provided

There are two alternative methods of fitting the generator to the engine. It may be strapped in a cradle or mounted by the end cover on the crankcase arm. In the latter method provision is made for chain adjustment through slotted holes for two of the three bolts, Fig. 1, center.

The starting motors are series wound and in the direct-acting type have either a squared shaft to take the sliding pinion or a screwed shaft for the self-acting momentum type of pinion.

The starting switches, Fig. 4, are plunger operated and can be located under the floor with the plunger projecting for foot actuation or interconnected with the pedal that brings the driving pinion into mesh with the flywheel. A flat resistance is incorporated in the switch which is included in the circuit on the first movement of the plunger and cut out when the plunger is pushed home. This insures easy meshing and a gradual start.

By using the third brush principle of regulation on the motor generator the moving parts are brought down to the minimum. The field coil for generator purposes is a shunt across the third brush and one of the main brushes, Fig. 3. When the car slows down below the minimum charging speed the unit automatically takes up its duties as a motor helping the engine. By this means the engine is prevented from stalling.

How Magnets Are Made

The method of manufacture of the magnets and the assembly of the windings are of particular interest. Raw stock in the form of seamless steel tube is fed into automatics

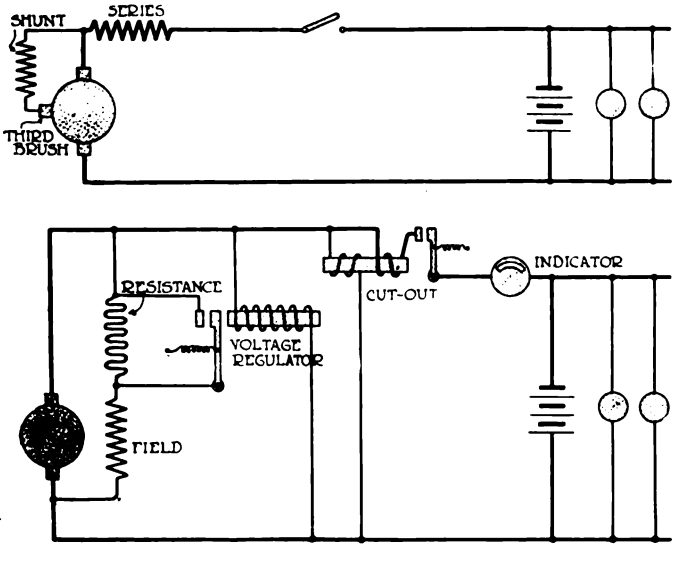

Fig. 3—Top—Diagram of connections on the motor-generator, showing the third brush control method. Below—Connections of the voltage-regulated generator and external circuit

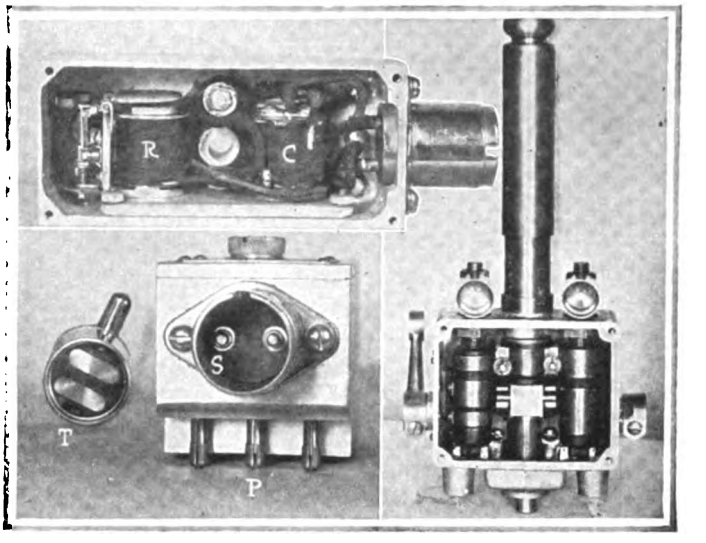

Fig. 4—Left—Interior and end views of the Bijur regulator which is connected to the outer circuits by a change over plug T. Right—Plunger type of starting switch with barrel contacts

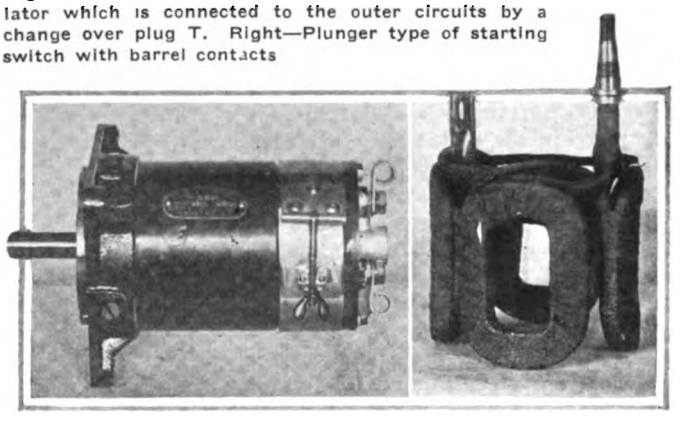

Fig. 5—Left—Bijur starting motor with squared shaft for sliding pinion. Right—Assembly of starting motor field coils

which machine inside and out and cut off to the required length, facing both ends accurately. The shells are then taken to a large press which punches out the holes which give access to the brushes. Until this year this particular operation was performed in the milling machine, which was naturally several times slower than the cold punch. The poles are drop forgings which require only slight grinding to true up. This is done by clamping twenty-four at a time on a mandril, which is inserted in an automatic grinder. The field coils are former wound and are assembled in complete sets, Fig. 5. After all holes have been drilled in the shell a set of windings is taken, four poles inserted and the whole then slid inside the shell. The assembly is then placed over an expanding mandril which forces the poles tightly against the inner machined surfaces of the shell, forming a good magnetic contact. While in this position the screws are inserted through the shell and tightened up with a machine screwdriver. The accuracy of the grinding and this method of assembling are such that a truly circular tunnel is obtained without further machining. Plug gages are used after this operation before passing on to the armature department.

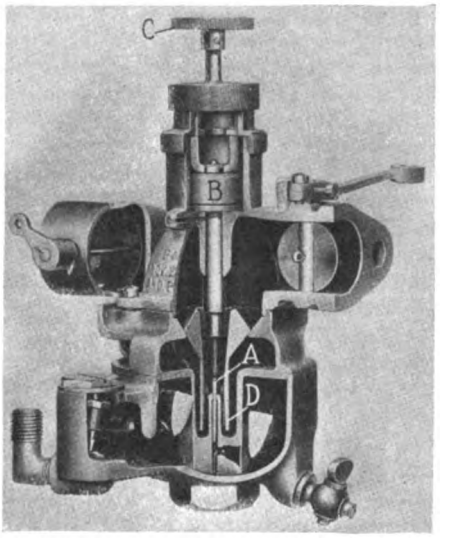
When complete all units are tested for grounds and shorts in the fields, commutator and armature windings. Motors are then given a long free run at a very high speed, after which comes a second test for possible shorts. Finally, motors are taken at random from the output and given brake tests. Generators are first given a test run of half an hour in which all regulator and brush adjustments are made. This is followed by a long run, each generator with individual battery and lights exactly as on the car, the speed being frequently changed over a wide range.

ACCESSORIES

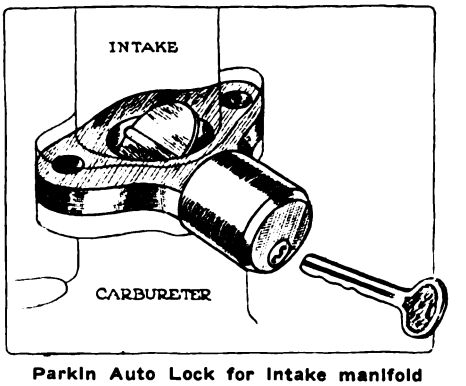
Diamond Drip-Proof Carbureter

TWO new, and extremely ingenious features, are to be found in the Diamond carbureter. The main design is on a simple, approved principle with a lifting valve to control the mixture. As is seen in the illustration, this valve controls both air and fuel passages as it has a metering pin *A* attached which varies the nozzle orifice as the valve rises or falls. At starting the whole of the air passes downward in the central well and then up through the hole pierced through the middle of the valve. When the engine picks up speed the valve lifts and the air stream then divides, so that the velocity of air actually passing the nozzle does not vary much. The metering pin lifts with the valve and thereby increases the size of the jet, calculation so proportioning the size of the pin as to secure a constant ratio between the air and gasoline admitted.

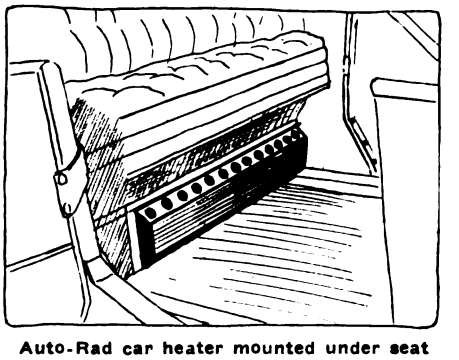
When idling, or when starting with the strangler closed, gasoline collects in the bottom of well *D* around the foot of the nozzle and the air bubbles through and provides a whiff of very rich gas to give acceleration as the throttle is opened up. This feature is well shown by demonstration which the makers are giving on an old Ford, exhibiting a great ability on high gear in heavy traffic.



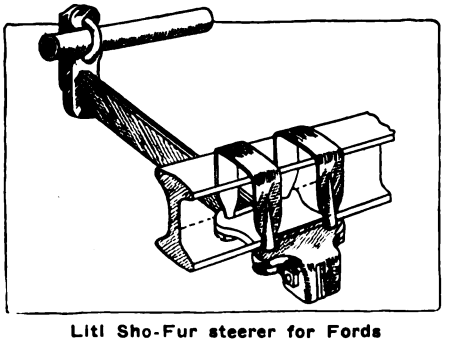
Diamond drip-proof carbureter



Parkin Auto Lock for intake manifold



Auto-Rad car heater mounted under seat



Litl Sho-Fur steerer for Fords

Graphite Dashpot

To steady the action of the valve a dashpot is needed, and a common fault of such dashpots is their tendency to stick. The inventor of this carbureter has hit upon the happy idea of using a solid block of graphite for the plunger *B* which is therefore everlastingly self-lubricating. Another clever feature is that the carbureter cannot leak or drip, as there is no outlet or intake below the level of the throttle. With an air pipe securely attached the carbureter will even operate under water. There is only one adjustment, this being on the metering pin and a control goes from the screw cap *C* to the dashboard.

Being a simple manufacturing proposition the carbureter is sold for the low price of $12.50, and it is made in sizes to suit cars of different make.—Diamond Carbureter Co., Jersey City, N. J.

Parkin Auto Lock

A new type of lock which places a shutter in the intake manifold when it is desired to prevent the car from being used is put out under the name of Parkin. The lock takes the position of a gasket between the carbureter and manifold flanges. In it is a butterfly valve which can be locked across the passage, thereby preventing the flow of gas into the motor. Each of the locks is different mechanically and there is no master key. The carbureter can be removed at any time without interfering with the lock. There is also a combined unit of lock and manifold on the market which can be purchased if desired in this form.—Parkin & Son, Philadelphia, Pa.

Auto-Rad Car Heater

A radiator for heating the automobile has been brought out under the name of Auto-Rad. The makers claim that the exhaust of an ordinary 40-hp. motor would heat an eight-room house, and there is no reason why a portion of this should not be taken for making the car comfortable in winter. The radiator consists of an enameled steel casing inclosing the radiating surface, thus permitting a circulation of warm air around the feet and under the body. The weight is given by the manufacturers as 4 lb. The upkeep cost for fuel is nothing since the exhausted gas which would otherwise pass out into the atmosphere is simply led through the radiator. Since the radiator is gas-tight the device is clean and odorless. The price of the device is $6. —Brevando Mfg. Co., Rochester, N. Y.

Litl Sho-Fur Ford Steerer

To bring the wheels of a car with reversible steering gear back in line the Litl Sho-Fur has been designed particularly for use on the Ford car. As shown by the illustration, it can be attached to any model T without machine work or without boring a hole and can be put on the car in 10 min. It is attached to the front axle of the car by two strap bolts. The means used for bringing the wheels back into line is a two-leaf spring of tempered steel. This passes through an eye clamped on to the tie rod and when this is moved to either side the spring tends to return to its center and bring the tie rod back to its normal position. The price of the device is $3.—White Mfg. Co., Cincinnati, Ohio.

Stewart Duplex Carbureter

To meet the demands for eight- and twelve-cylinder motors the Stewart Duplex carbureter, which is in reality two carbureters in one, has been designed. The principle of the single Stewart carbureter is followed, but all the essential elements such as the metering pins, metering valves, mixing chambers, throttles, and adjustment are all separate. In order to obtain uniform results in both sides of the V, this duplex model is so arranged that the throttle and adjustment can be perfectly synchronized thereby equalizing the two motor sets.

The only function which is the same for both sides of the carbureter is the float bowl and the mechanism which keeps the gasoline at a constant level. There is also a single air intake port which works from a single hot air tube and stove on the exhaust manifold.

The Duplex carbureter is illustrated in the sectional view. The carbureter operates on a metering principle which can readily be understood from the illustration. With the motor at rest the main air passages are closed because the air valves *A* rest on their seats. As soon as the engine starts to rotate a vacuum is formed lifting these valves from their seats admitting air and drawing gasoline through the aspirating tubes *B*, a small amount of air is drawn through the primary air passages and up around the flared top of the aspirating tube. This flare on the end of the tube is for the purpose of spreading the gasoline in a film in which condition it is picked off the rim by the air which passes this point at a high rate of speed.

Only One Adjustment

The more the throttle is opened the more the air valves will lift and the more gasoline will be allowed to pass by the tapered metering pins. The higher the valves are lifted the greater will be the opening around the metering pins, thus increasing the gasoline supply. The only adjustment possible in this carbureter is that of the relative position of the metering pin to the opening in the bottom of the aspirating tubes and when this is once made, it should be permanent.—Detroit Lubricator Co., Detroit, Mich.

Magnalite Alloy Pistons

Aluminum alloy pistons have been much in the public mind of late especially in the automobile engineering world. Among other advantages planned for Magnalite pistons are less vibration and a cooler motor, the aluminum alloy used in their construction being lighter than aluminum and stronger than cast iron. The light weight minimizes vibration and the higher conductivity effects a quicker transference of the heat to the waterjacket. These pistons are manufactured to fit all cars. The rings used may be of either Magnalite or the ordinary cast iron type.—Walker M. Levett Co., New York City.

Guardian Robe Lock

For locking the robes on a car which is abandoned by the driver temporarily, a combination device has been brought out whereby these can be clamped to the robe rail without danger of removal except by tools. It is intended to prevent the theft of robes, raincoats, grips, gloves, dusters, packages and other articles from the car and also eliminates the necessity of dragging the robes into the restaurant or home when the car is stopped.

The Guardian lock operates by combination, thus obviating the necessity for a key which can be lost. There is no ratchet on the lock and it can be closed in any position. The device is 3¾ in. high by 2¼ in. wide when closed. The jaws which clamp over the robe are 1¾ in. wide. The lock is made of heavy sheet steel nickel plated. The price of the device is $1.—Mechanical Products Co., Cleveland, Ohio.

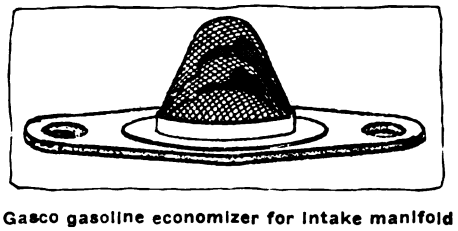
Jasco partitioned tank for speedsters, etc.



Gasco gasoline economizer for intake manifold

Jasco Tank Improvements

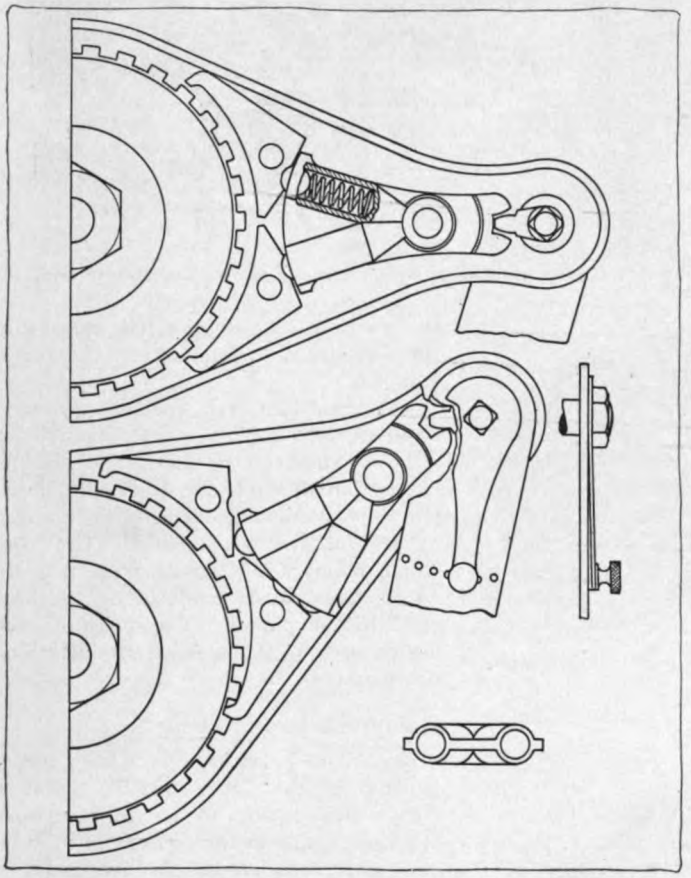
Several new features have been incorporated in the Jasco line of seamless drawn steel tanks. A rectangular tank has been added to the stock, and may be had with rounded or concave ends; a special square Packard tank, is supplied 12 by 14 by 32, holding 21 gal., and ready for installation, having all fittings. The price is $20, or, with gasoline gage, $23. A cylindrical tank is built for roadster, speedster or racing cars with a separate compartment in one end for oil and a splash partition in the middle of the gasoline compartment; these tanks are made in 14, 16, 18, 20 and 24-in. diameters and any length.—Janney, Steinmetz & Co., Philadelphia and New York City.

Gasco Gasoline Economizer

In order to more perfectly vaporize the fuel a device under the name of Gasco is being marketed which is placed in the manifold-carbureter connection. The Gasco device contains a set of screens intended to break up the globules of gasoline drawn from the carbureter. Another function of the screens is to prevent inflammation due to backfire as the screen will act in the same way as in a miner's lamp. The Gasco can be secured in any size, the prices ranging from $1 to $1.50.—The Gasket Supply Co., Philadelphia, Pa.

Absorber Permits Limited Free Motion

Device Invented by Lancaster Man Utilizes Ratchet and Pawl To Introduce Resistance to Violent Spring Action



Figs. 1-2—Shock absorber in normal position with pawls disengaged; shock absorber after obstruction is encountered with lower pawl engaged

A NEW shock absorber has been brought out in which the designer has endeavored to produce a device which will not offer any resistance within a certain amount of spring action. This permits the car to pass over smaller obstructions and depressions without any interference with the natural spring action. Beyond this range the action of the spring is checked in proportion to the severity of the depression or obstruction in the road. The inventor is E. H. Kreider, of Lancaster, Pa.

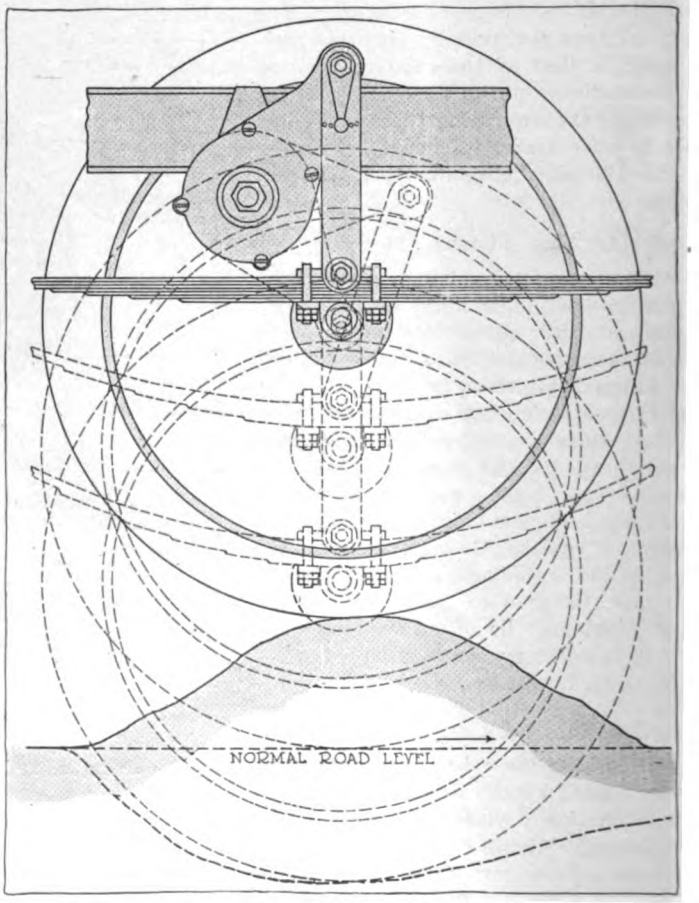
Uses Ratchet and Pawl

The means provided to accomplish this result are shown in Fig. 1 where it will be seen that the pawls of a ratchet and pawl action are both disengaged from the ratchet wheel and remain so for a limited amount of axle movement. When an obstruction higher than the above limit is encountered, the device, which is attached to the body of the car, will turn upward as in Fig. 2 and automatically drop the lower pawl into the ratchet, turning the ratchet wheel against resistance during the recoil movement of the spring. This prevents the up-throw of the body.

Assuming that the car has again taken its normal position with both pawls out of mesh and the wheel encounters a depression in the road, the wheel and axle will drop quicker than the body and thereby cause the shock absorber to turn downward when the upper pawl will engage the ratchet and at the time the body tends to drop, an upward pressure is exerted by the shock absorber. Thus in either case whether the car encounters a depression or an obstruction, the shock absorber is designed to adjust itself without resistance and only comes into action on the return movement.

As will be seen by Fig. 3, the greater the obstruction or depression, the more the device comes into action, that is if it requires 50 lb. to move the device at a point near the neutral position, it will require almost 100 lb. to move it when on a high obstruction or deep depression. This is brought out in Fig. 3, showing the shorter leverage at the extremes in a case of depression or obstruction at the extremes.

Assuming again, that the road conditions are such that the car has a tendency to rock up and down a number of times in succession and with such violence that the shock absorber will move beyond the free action space both ways, the pawls are so designed as to remain engaged across the neutral space and cause the device to act constantly until the body of the car again settles down to its normal position at which time both pawls again drop out, permitting free action of the springs as before. The index pin and latch shown at Fig. 4 is for the purpose of changing the position of the neutral space to compensate for various makes of cars and also for light and extremely heavy loads.



Figs. 3-4—The greater the obstruction or depression the more the device comes into action. This is brought out in the above illustration which shows the action of the device on encountering a large obstruction above the normal road level and also a depression

Winter Driving

IF a national propaganda results from the resolution of the National Association of Automobile Accessory Jobbers to boost winter driving, every branch of the automobile industry will benefit. The car owner will benefit by the elimination of the idea that the automobile is merely a warm weather utility and will get nearly twice as much use out of his car. The manufacturer, the dealer, the garageman and the jobber will benefit because the industry will be more uniform in its demands the year round, rendering production and sales less a matter of seasons, and tending to straighten out the undesirable fluctuations of the demand and supply curve throughout the country, while the dead storage problem will be minimized. Such a condition may seem Utopian and at present unattainable, but results do not come without effort and the benefits involved are of such magnitude as to be worth every effort to attain them.

An editorial in THE AUTOMOBILE for Sept. 16, entitled The All-Weather Car, pointed out the increasing tendency of car owners to take advantage of the all-weather bodies for keeping their cars in active service during the cold weather when they have formerly put them in dead storage. The dealers report a steadily increasing demand for this type of car and, in fact, it would seem that conditions are auspicious for the launching of a boom for winter driving.

Automobile History

THE automobile industry in America has a history little understood not only by the masses owning automobiles but understood very little by several of the oldest pioneers, those who lived through the days of 25 years ago when the earliest efforts were being made. These pioneers are with us to-day, but so busy have they been in working out their own problems of design, manufacture and merchandising that they have had no time to pick up and bring together the threads of early endeavor.

This week THE AUTOMOBILE publishes the opening chapter of its History of the Automobile Industry in America, a work that has been in preparation for several years and on which much searching has already been done to lift the cover from early efforts before those who did the work have passed into the great beyond of forgetfulness. Although much has been gathered, much still remains to be told of a tale that stands without parallel in America. No other industry is more deserving of having its early efforts laid bare, and now that an industry with a manufacturing life of scarcely twenty-five years has attained such world-wide importance it is imperative that its development be accurately recorded.

Hotchkiss Drive

STUDY of the new chassis that have been described in THE AUTOMOBILE during the past six months shows that the Hotchkiss drive is distinctly on the upward trend in popularity. Commencing with small cars it is now being adopted for larger vehicles and is even making steady progress in the truck field.

Now, if it is satisfactory practice in a truck to take drive and torque stresses on the springs, there should be no doubt about the efficacy of the system for passenger cars; for the stresses in a truck are far heavier than in any lighter vehicle. There is much to be said on both sides, and the protagonists of torque and radius rods have much of the engineering theory in their favor, but in practice the advantage of simplicity ranks very high.

Trucks and Food

THE decision of the British government to withdraw the 33 1/3 per cent import duty on commercial vehicles will be of real assistance both to manufacturers in America and to consumers in England. From the British viewpoint it is important above everything else that the wheels of industry should run smoothly, and a plentiful supply of motor trucks has become a vital necessity to almost every trade; how vital has only been realized at the full in England since war absorbed the automobile equipment of industry throughout the United Kingdom.

A free supply of inexpensive trucks will prevent rise in price of almost everything that has to be handled in small quantities, especially foodstuffs, and had the tariff been maintained it would, after the war is over, have retarded the return to normal prices of all sorts of articles.

British Exempt Trucks from Tax

Englishmen Intervene to Free American Commercial Cars from 33⅓ Per Cent Duty

LONDON, ENGLAND, Oct. 15—The order of Chancellor of the Exchequer McKenna, imposing an import duty of 33 1/3 per cent on all foreign cars has been modified to exempt trucks and truck parts. This was brought about by an immediate storm of protest not by American manufacturers but by Englishmen who have learned the value of American trucks at this time. It was brought out that American trucks have been of great advantage to the armies of England and to merchants whose trucks have been commandeered for use by the British army.

—

Robinson Leaves Case

RACINE, WIS., Oct. 23—Richard T. Robinson, for many years secretary of the J. I. Case T. M. Co., Racine, Wis., has resigned and will move his residence to California. He is succeeded by W. F. Sawyer, who has been associated with the Case company for fourteen years and until now was manager of the sales department. Ellis J. Gittings succeeds Mr. Sawyer and R. B. Coleman is promoted to manager of the collection department. Mr. Robinson is one of the founders of the Case company. Thus far the company has made no announcement of the election of a general manager to succeed F. Lee Norton, who retired a short time ago.

New Era Touring Car $660

JOLIET, ILL., Oct. 23—Among the companies to enter the field for the first time with a car for 1916 is the New Era Engineering Co., this city, its product being the New Era touring car to sell at $660. The power plant is a four-cylinder 3⅛ in. by 4½ in., is block cast, the cylinders being integral with the upper half of the crankcase. Gear reduction is 4¼ to 1.

Cooling is obtained by the thermo-syphon system, ample space for circulation of water being allowed on all sides of the valve chambers, while several openings are provided between the cylinder proper and the cylinder head to eliminate as far as possible any restriction in the flow of water. A combined pump and splash lubricating system is used while the fuel supply is from a gravity tank located under the front seat, where it is readily accessible.

The electric starting and lighting system is an Allis-Chalmers, operating through a silent chain. The gearset is in a unit with the motor and is of the three-speed selective type. The gears are heat-treated chrome nickel steel and run on double rows of Hess-Bright bearings. Left drive and center control is furnished for domestic trade or right drive for export trade.

The clutch is a Raybestos-lined multiple disk dry-plate type. The rear semi-floating axle is fitted with chrome nickel steel shafts and Hyatt roller bearings. Service brakes are of the contracting band type and the emergency expanding bands inside the drums. An Atwater Kent ignition system with automatic spark control is used.

—

Overland Elects Officers—Earl a Director

TOLEDO, OHIO, Oct. 26—C. A. Earl was elected a director and one of the vice-presidents of the Willys-Overland Co. at the annual meeting of the stockholders this afternoon.

The following directors and officers were re-elected: President, J. N. Willys; vice-presidents, Isaac Kinsey, O. S. Jameson, H. L. Shepler, H. T. Dunn; secretary, R. R. Scott, and treasurer, Walter Stewart. Representatives of 165,000 shares of common stock voted.

Treasurer Stewart in a general report to the stockholders said: "The financial condition of the Overland company was never so good as now. The company owes nothing on merchandise notes. Its indebtedness to its bank represents its only outstanding paper. It is taking advantage of all discounts for cash, and its average cash balances for the last four months have been in excess of its total debts."

At the close of the stockholders' meeting the directors elected the following executive committee: J. N. Willys, H. T. Dunn, H. T. Shepler, C. S. Jameson, R. R. Scott and Walter Stewart.

New Chase Truck for $1,650

SYRACUSE, N. Y., Oct. 21—The Chase Motor Truck Co., this city, has added a 1-ton model to its present line, known as model A. The new model will be a worm drive type with a four-cylinder unit power plant of the L-head type, 3½ by 5⅛. A few of the features are price of chassis in paint with cab, $1,650; wheelbase, 140 in.; front axle, I section, rear, Sheldon worm drive; Holley carbureter; water-cooled; Bosch ignition; Brown-Lipe selective sliding gear, three-speed transmission, case attached to flywheel housing; weight on rear axle, 53 per cent; payload on rear axle, 83 per cent; fuel tank capacity, 18 gal.; oil tank capacity, 1¾ gal., and loading space, 8½ ft. back of driver's seat. Electric lighting and starting equipment will be furnished at extra cost. Deliveries will commence Dec. 1.

French to Boycott Ford Cars

Manufacturers, Dealers and Owners Indignant at Anti-Loan Campaign

PARIS, FRANCE, *Special Cable to* THE AUTOMOBILE—French dealers have decided to boycott Ford cars from now onward and to do all they can to prevent their sale in France by making an appeal to the public to answer Henry Ford's notorious "tin can" utterance by shunning his car. The indignation created throughout France and England by Ford's anti-loan speeches is very great as shown in many letters to newspapers. It is probable that the sale of Fords, which has been very large in England and perceptible in France, will be reduced considerably for a time at least.

—

Morris Eckhart Heads Auburn

AUBURN, IND., Oct. 23—Following the death of Charles Eckhart, president of the Auburn Automobile Co., this city, Morris Eckhart has been elected president. F. E. Eckhart is first vice-president, J. I. Farley, second vice-president and sales manager, W. H. Denison, secretary, and F. B. Sears, treasurer.

—

I. H. C. Reduces Truck Prices

CHICAGO, ILL., Oct. 23—The International Harvester Co. of America has reduced the prices on four types of trucks, for loads of 1000, 1500 and 2000 lb., ranging from $600 to $1,500. Two new models have been added this year, one of 1500 lb. capacity selling for $950 and a ton-truck the chassis of which sells for $1,500.

Two six-story additions to the factory at Akron, Ohio, will double the present manufacturing equipment. The following list gives the new prices:

Model MA, 1000 lb., air-cooled	$600
Model M, 1000 lb., water-cooled	710
Model E, 1500 lb., heavy-duty motor	950
Model F, 2000 lb., chassis only	1,500

1000 Chevrolets for St. Louis

ST. LOUIS, MO., Oct. 23—The recently organized Chevrolet Motor Car Co. of St. Louis has arranged with the Chevrolet company of New York for the shipment to St. Louis of 1000 Chevrolet 4-90 cars between now and Jan. 1, when it is expected the local assembling plant of the company will be ready for operation.

Shortage of Gasoline in Paris

Fuel Famine for First Time Since War Began—Price Now 42 Cents

PARIS, Oct. 9—For the first time since the war began Paris has experienced a real shortage of gasoline. This week supplies have failed to reach the retail dealers, many of whom have ceased to supply customers, while others refuse to sell more than 1 gal. to any one person. The correct explanation of the shortage appears to be that vast supplies have been requisitioned at the various refineries by the military authorities. This is not surprising in view of the enormous aeroplane activities of the French, and the possibility of an advance, which will of course throw greater work on the automobile transport department. The recent attacks in the Champagne and Arras districts have been responsible for a great increase in gasoline consumption by reason of the thousands of trucks employed in carrying ammunition to the guns, in moving troops, and in clearing away wounded. It is obvious that the military authorities will lay hold of greater reserves than usual in view of the present attacks becoming general.

The average retail price of gasoline around Paris, excluding the city of Paris, where there is a special tax, is now 42 cents per gal. Some dealers are selling at 45 cents per gal. Three years ago the average price was 27 cents, and just before the war gasoline was sold round Paris at 33 cents. There has been no additional taxation during this period. Benzol, which was largely employed for commercial vehicles, taxicabs, and by manufacturers for chassis testing, has been unprocurable since the war, all supplies having been requisitioned for making explosives.

—

Michigan Service Managers Organize

DETROIT, MICH., Oct. 26—Service managers and other factory representatives from most of the automobile manufacturing concerns in Michigan and Northern Ohio met in convention here to-day and formally organized the Automobile Service Managers' Association of Michigan. Its principal object and purpose is to determine the best methods of conducting the work of the manufacturers service and repair departments, to furnish a maximum of service to the mutual advantage of all concerned, to improve and facilitate co-operation among manufacturers, dealers and owners and to promote the more liberal policy of helpfulness to the purchasers of motor vehicles that is reasonable and equitable to all.

Among the cities in northern Ohio where automobile concerns are located and which are included in the new association, are Toledo, Bowling Green, Lima, Sibley and Fremont.

Cleveland has not been included on the list of manufacturing centers to be looked after by the new organization because it is generally thought that before long a service managers' organization will be started there.

Officers Elected

C. R. Lester, manager of the service department of the Packard Motor Car Co., was elected president of the association; E. V. Rippingale, Hudson Motor Car Co., vice-president; D. H. Haselton, Regal Motor Car Co., secretary and treasurer; H. G. Fitch, Willys-Overland Co.; J. L. Kenyon, Cadillac Motor Car Co.; Charles Gould, Maxwell Motor Co.; C. W. Matheson, Dodge Bros.; Pierre Schon, General Motors Truck Co., and A. O. Weise, Oakland Motor Co. were elected directors.

—

Kelly-Springfield Tire to Reduce Common Par to $25

NEW YORK CITY, Oct. 27—At a special meeting the board of directors of the Kelly-Springfield Tire Co. adopted a resolution that the certificate of incorporation be amended so as to reduce the par value of the common stock from $100 per share to $25 per share.

A special meeting of stockholders will be held on Nov. 30 to act on the resolution. The par value of the 6 per cent cumulative preferred and the 7 per cent second preferred stock will not be reduced.

—

Payne Is Manager of Gibson Co.'s Automobile Department

INDIANAPOLIS, IND., Oct. 23—J. H. Payne has been appointed manager of the automobile department of the Gibson Co. Prior to his present connection Payne was manager of the small motor department of the General Electric Co.'s local sales organization.

—

Hayes Truck Wheel Co. Formed

ST. JOHNS, MICH., Oct. 26—The Hayes Motor Truck Wheel Co. has been organized in this city with a capital of $100,000. Officers have been elected as follows: President, C. B. Hayes; first vice-president, N. S. Potter; second vice-president and timber manager, W. C. Morrey; secretary-treasurer and general manager, A. D. Smith, and superintendent, H. J. Keller. The company, which is occupying the factory of the St. Johns Manufacturing Co., expects to be in operation by Nov. 1, and a sawmill will be operated in conjunction with the plant.

Canadian Ford Melon

600 Per Cent Dividend—Capital Increased from $1,000,000 to $10,000,000

DETROIT, MICH., Oct. 26—At the annual meeting of the Ford Motor Co. of Canada it was decided to increase the company's capital stock from $1,000,000 to $10,000,000. A 600 per cent stock dividend to shareholders has been recommended to the directors. Six million dollars par value of new stock is to be issued to the present stockholders who will receive six shares for every share they now hold. Six million dollars will be transferred from the company's surplus fund to capital stock.

Net earnings of the company during the fiscal year 1915 amounted to $3,200,000 in round figures and the surplus is about $7,000,000.

The directors of the company were reelected. They are: Henry Ford, James Couzens, Frank L. Klingensmith, Gordon M. McGregor and W. R. Campbell. The officers of the company now are: Henry Ford, president; Gordon M. McGregor, first vice-president, treasurer and general manager; James Couzens, second vice-president; Frank L. Klingensmith, third vice-president; W. R. Campbell, secretary.

Canadian Ford Stock Up

DETROIT, MICH., Oct. 26—Shares of the Ford Motor Co. of Canada which were quoted $1,500 yesterday, were quoted $2,000 bid and $3,000 asked this morning on the local stock exchange. Some brokers predict that before the end of the week the stock will go up between $500 and $1,000 a share.

—

Canadian Ford to Expand

FORD, ONTARIO, Oct. 23—By Jan. 1 a new mahcine shop, 700 by 45 ft., and a foundry, are to be ready for occupancy by the Ford Motor Co. of Canada, Ltd. This will give employment to over 500 more men. Now there are 1920 on the pay-roll, 1730 in the shops and 190 in the offices. There are eight concerns located in Windsor, Ford, Walkerville or vicinity, making parts for the Ford cars, and they employ all told 1153 men. The sociological department of the Ford company has gathered information tending to show that 15,363 people living within the vicinity of the plant are either directly or indirectly being supported by the company.

Although this the dull season and the lack of material is still prevailing, the Canadian company's business is increasing in such a way that this season's output will be more than 35,000 cars.

Packard Surplus $3,713,747.22

Gains $1,915,926.80—Assets $21,814,153.71—29,936 Cars and Trucks Built

DETROIT, MICH., Oct. 22—During the fiscal year ending Aug. 31, 1915, the surplus of the Packard Motor Car Co. was $1,915,926.80 ahead of the total at the end of the 1914 fiscal year, totaling $3,713,747.22 as compared with $1,797,820.42 in the previous business year, or an increase of over 50 per cent. The total number of cars and trucks built by the company to Aug. 31 was 29,936, nearly 8000 being trucks.

The assets of the company were $21,814,153.71 or $3,850,533.09 or over 20 per cent larger than those of 1914.

Among the assets one of the items which shows the greatest increase is that for tools, the total amount credited to the account being $1,194,101.65, or $522,089.70 more than in 1914. This, of course, is due principally to the fact that the construction of sixes and fours has been abandoned and that entirely new tool equipment was needed for the making of the twelves.

The next item which shows the biggest increase is that of construction work, which has passed the $500,000 mark while in 1914 it totaled less than $17,000. The raw material account shows an increase of over $1,000,000 totalling $7,423,875.93. This includes not only the raw material, but also completed cars and work in progress on cars or trucks.

The investments of the company in stocks, bonds and short time securities have been very heavy in 1915, this account showing an increase of over $1,100,000 as compared with 1914.

While the cash account for vehicles in transit to dealers is over $200,000 lower for 1915 than for 1914, the account as to cars in transit to branches shows an increase of over $310,000.

Among the liabilities the item most conspicuous is that of accounts payable and which means or represents such accounts as accrued payroll, current invoices, not due, deposits on vehicle orders, etc. The total for the past year is $2,335,907.57, or $1,449,126.58 over 1914.

—

Beal with Marmon

INDIANAPOLIS, IND., Oct. 23.—W. A. Beal has taken a position with the Nordyke & Marmon Co. as traveling representative. Mr. Beal is well known in the automobile selling trade through his connection with the Stevens-Duryea Co. since 1911, first as Pacific representative with headquarters at San Francisco, and later in charge of outside territory between Kansas City and Chicago branches.

—

Moon Buggy Builds Roadsters

ST. LOUIS, MO., Oct. 22—The John W. Moon Buggy Co. of St. Louis has submited a bid for the delivery of 500 roadsters in New York for shipment.

Of the preferred shares, there are 50,000 outstanding and 30,000 unissued. Par value of both common and preferred shares is $100.

Elcar Is 1916 Name for Pratt

Elkhart Carriage & Motor Co. Is New Company Style—Car to Sell for $775

ELKHART, IND., Oct. 23—A change in both name of car and company marks the entrance of the former Elkhart Carriage & Harness Mfg. Co., this city, maker of the Pratt car, into the 1916 field. The car for 1916 will be known as the Elcar while the company's corporate name has been changed to the Elkhart Carriage & Motor Car Co.

The Elcar will be made in a touring and roadster model at $775. The four-cylinder motor is of the high speed, high-efficiency, long-stroke type, having cylinders and waterjackets block cast, the cylinders measuring 3½ by 5 in. Much attention has been given to an effort to lighten all reciprocating parts and for the attainment a well-balanced power plant.

The lubrication system is a combination of the splash and force feed, a plunger pump operated by the camshaft, forcing oil through all the main bearings, while the connecting-rods are fitted with scoops by which oil is distributed to the cylinder walls and pistons. Thermo-syphon cooling in connection with a tubular radiator and fan is used.

The motor, clutch and gearset form a unit, mounted directly to the main frame at three points, the third point in front being a large bearing on a common center with the crankshaft. Three speeds are provided with center control. Gears are nickel steel, heat treated, with annular ball bearings. The clutch is a cone type with easy engagement springs under the facing.

The electric system is complete and self-contained, ignition being gained through a Delco distributer, while starting is accomplished by an Aplco motor-generator operating through a silent chain inclosed in front of the motor gearshifts.

The wheelbase of the Elcar is 114 in. The full streamline effect is obtained in the Elcar, and the doors are wide with concealed hinges. Included in the equipment are one-man top, curtains and cover, windshield, electric lights and extra demountable rims and carrier and a full equipment of tools in both the five-passenger touring and roadster models.

—

New Billings & Spencer Co. Formed

HARTFORD, CONN., Oct. 25—At a meeting of the stockholders of the Billings & Spencer Co., held this morning, the stockholders ratified the recommendations of the board of directors to dis-

pose of the assets, good will and business in consideration of 12,000 shares of the new company at $25 a share. The board of directors of the old company was also authorized to vote on the 12,000 shares of the new company in favor of the issue of 8000 additional shares at a par value of $25 to be sold at not less than $37.50, the right to subscribe being offered first to stockholders of the Billings & Spencer Co., and the price to be fixed by the directors of the new company. By vote of the stockholders the old company went out of existence.

—

Townsend Brings Out Tractor

BELOIT, WIS., Oct. 22—The Townsend Mfg. Co., Beloit, Wis., is bringing out a new gasoline tractor for general purposes in the city and on the farm. It is propelled by a gasoline engine rated at 10 to 20 hp. and is built in several types. The tractor may be used for plowing, seeding, cultivating and similar work as well as for filling silos, hauling farm loads, etc. The tractor in a recent test handled three 14-in. plows in sod which had not been plowed for forty years and which averaged 8 to 11 in. in depth. It was turned over at a cost of 11.2 cents per acre for fuel and 3.5 cents for grease and other lubricants.

—

Tower Truck in the Field

GREENVILLE, MICH., Oct. 23—R. J. Tower of this city is bringing out the Tower truck which is to be manufactured by a company to be known as the Tower Motor Truck Co. The first model was recently completed in the machine shop and foundry of Mr. Tower. It has a Continental four-cylinder block motor, 135 in. wheelbase and Timken axles.

—

New Continental Drop Forge Plant

MUSKEGON, MICH., Oct. 22—Work has been begun on the construction of the new drop forge plant of the Continental Motor Manufacturing Co. A building 60 by 180 ft. will be erected on half of property fronting on Muskegon Lake, the site having been recently purchased, and the other half of the site will be kept open for future building operations.

—

Toledo Firms to Enlarge

TOLEDO, OHIO, Oct. 22—Nearly $300,000 will be spent immediately on extensions of two local makers. The Toledo Machine & Tool Co., will build a three-story addition costing $200,000 to be 400 by 100, of steel, brick and concrete construction. The new structure will increase the plants capacity 35 per cent.

The Electric Auto-Lite Co. has broken ground for a $74,000 addition to its Champlain Street plant. It will be 385 by 103, three stories and of concrete and steel construction. The plan provides for a fourth story.

Record Year for Locomobile

—

Truck Orders Large—Domestic Business Shows 12% Gain Over Last Year

BRIDGEPORT, CONN., Oct. 25—Due to the war the Locomobile Co. of America has enjoyed the most prosperous year in its history. Although officials of the company are reticent when questioned about war orders, it has been learned from an authoritative source that nearly 700 trucks of the 3-ton type have been shipped to the Allies, in addition to 100 pleasure cars for the Russian army, a special car for the Grand Duke Nicholas, and 140 pleasure-car chassis for the Russians. The latter will be equipped with soup kitchens.

It was announced to-day that with the year ending Aug. 31, the domestic business had shown a 12 per cent increase over last year, practically all passenger car trade.

Increase in the Locomobile company's business has meant much to other Bridgeport industries which were more or less affected by the tariff regulations. The Locomobile company has divided a great deal of its work among Bridgeport factories, principally the foundries.

—

Six Entries to Date for Sheepshead Meet

NEW YORK CITY, Oct. 27—Six entries for the 100-mile invitation race for the Harkness gold cup have been made to date for the Sheepshead Bay Speedway meet on Election Day as follows: Resta, Burman, Aitken and Mulford, in Peugeots; Rickenbacher, Maxwell, and De Palma in his Mercedes. De Palma, it is expected, will get his car into shape for the race. The trophy is open only to drivers who have won big races this year and is to be the object of competition annually. A gold miniature of the cup will be presented to the winner on Election Day.

Burman in his Blitzen Benz, will try to make a lap in a minute or less, or at the rate of 120 m.p.h. Juan Domenjos will make several flights in his aeroplane and several flights will be made by Frank Goodale in the Stevens dirigible.

Prince Paul Troubetzkoy is planning to race President Harkness in a match race at the track on that date.

—

New Six-Story Addition for Brown-Lipe-Chapin

SYRACUSE, N. Y., Oct. 26—The Brown-Lipe-Chapin Co., this city, has begun an enlargement of its plant which will give it at least 50 per cent greater capacity and will involve an expenditure of $750,000. The factory structure upon which work is now under way is to be six stories, 190 by 70 ft., and will be built of reinforced concrete, corresponding in exterior appearance with the main building erected six years ago.

Extension of the case-hardening plant, to be made at once, will be in proportion to the general plan of doubling the entire plant capacity. Five months are allowed for the completion of the six-story addition.

More than 1600 persons are employed in the factory and office of the company. After the addition is finished at least 500 more will gradually be placed on the pay-roll.

With the plant capacity doubled, it will probably be possible to do away with night work. For several months the plant has been operating 24 hr. a day.

—

Splitdorf Plans 75% Expansion

NEWARK, N. J., Oct. 18—The Splitdorf Electrical Co. has adopted plans for additional factory facilities in the shape of a new building 300 ft. long by 50 wide and six stories high, to be erected adjoining the present main factory in this city. It will be built of brick, and will increase the present plant space 75 per cent or about 100,000 sq. ft.

The new factory is expected to be finished within six months and will contain much additional equipment.

At the present time, the output of magnetos is 1500 a day, but plans contemplate an output of 2000 a day by next spring when the new building is completed. There are 1500 employees in the main plant, 300 in the Sumter, 300 in the Apple and 200 in the third plant.

—

May Forbid Starting Engines Before Ferry Docks

NEW YORK CITY, Oct. 21.—Ferry companies in this city are being fined $500 for each offense by the United States Government for allowing automobiles to start their engines before the boats are actually tied up in their slips. Under the Federal law governing ferry boats the companies may refuse to permit an automobile on any of their boats until the gasoline tanks are emptied, and it is stated that if the drivers of cars continue in violating the law by running their engines, the ferry companies will enforce the last named one in regard to the use of gasoline.

—

Dingley to Undergo Operation

LOS ANGELES, CAL., Oct. 20.—Bert Dingley, the veteran race driver and well-known automobile man of this city, who was injured in the wreck of the Ono car on the Tacoma speedway, July 4, 1914, has returned to the Tacoma General Hospital to undergo another operation in an effort to save his foot.

Co-operation the Slogan Brought Out at Electric Vehicle Assn. Convention

To Develop Business All Must Pull Together— Central Stations Must Do Their Share, Especially in Promoting Sales of Electrics for Municipal Work

CLEVELAND, OHIO, Oct. 22—Reviewing the work of the sixth annual convention of the Electric Vehicle Association of America, which closed here to-night, the outstanding feature was the plea for co-operation between the various branches of the industry. It was recognized that in order to develop the business and make it grow, all who are in any way interested in it must pull together. Competition with other classes of motor vehicles was taken full account of, and petty differences within the industry must be forgotten.

That the central station is a big factor in the promoting of the industry was most strongly emphasized, and while it is not expected that the central station interests will do more than their share in the developing of fields for electrics, the manufacturers expect them to at least do their part. As to the selling of electrics for various municipal work, such as fire, police, ambulance, street cleaning and other service, the central stations were pronounced the one big factor, for it is through their interests that the city officials can be properly approached and influenced.

The electric taxicab came in for a great deal of interest, as well as the light delivery electric, for which there is very evidently a big field.

Close Relations with N. E. L. A.

Along the line of co-operation, the association formally voted to get into closer harmony with the National Electric Light Association, which is a very strong organization in its field. It was immediately realized that the interests of the two organizations are very closely allied, and that each can help the other. Hence the convention instructed its incoming officers to do all they can to promote a close relationship, with possible affiliation with the N. E. L. A. as the goal. There was strikingly little dissention from this future plan.

One other point on which great emphasis was placed was as to the selling of electric commercial cars in fields for which they are best adapted, and not trying to force them in cases where it is a well-known fact that gasoline types are better. There is a distinct field for both the electric and the gasoline truck, it was insisted, and it is a big mistake to try to sell on other than scientific lines. The first step in a sale is to analyze the transportation problems involved and then to be assured that the machines will pay. Unsuccessful installations are bad advertisements and do not promote additional sales.

That electric garage service is not at all satisfactory at the present time was brought out. The makers and central station men feel that the trouble is largely along this line, for people must be assured of good and efficient care of the vehicles else they will not buy. The properly equipped electric garage, in fact, is positively necessary to the development of the electric vehicle industry.

Nearly 300 in Attendance

The attendance ran close to 300, and a good proportion were central station men. There were eighty-seven central station operators on hand, fifty-two battery men, forty vehicle manufacturers or their representatives, sixty-five electric accessory men and forty-five having miscellaneous connection with the industry.

The registration records showed that the gathering was by no means from any one section of the country, nearly all large cities being included. For instance, an unofficial count showed that there were fourteen from New England, ten from Philadelphia, sixteen from Detroit, two from Los Angeles, fifty-one from New York City, and one or more from many other localities. Naturally, due to convenience, many of Cleveland's electric men came, the total from the city being 115.

The convention elected as officers for the coming year four who are connected with current producing companies, two who are members of electric car manufacturing businesses, and one identified with an electric engineering concern. W. H. Johnson, vice-president of the Philadelphia Electric Co., Philadelphia, was made president. Other officers are E. S. Mansfield, Superintendent Operating Bureau of Accounts, Edison Electric Illuminating Co., Boston, vice-president; H. M. Edwards, auditor, New York Edison Co., New York, treasurer; W. H. Blood, Jr., Stone & Webster Management Assn., director; P. D. Wagoner, president, General Vehicle Co., Long Island City, N. Y., director; G. H. Kelly, secretary-treasurer, Baker, R. & L. Co. Cleveland, director, and the retiring president of the association, J. F. Gilchrist, vice-president, Commonwealth Edison Co., Chicago, director.

Although no statement was made relatively to these selections, which were voted unanimously by the convention, it is probable that the central station people were made vitally interested in the association in this way in order to cement their co-operation with the manufacturers more and more.

Convention in Detail

Following the welcoming of the delegates to the City of Cleveland by Bascom Little, president of the Cleveland Chamber of Commerce, the convention got under way with the address by President J. F. Gilchrist. He said in part:

"It may be said that the work of the Association this year has been consistent and persistent, rather than spectacular. A great deal of attention has been given to the accumulation of data and information useful to the members, and equal attention has been paid to publicity of value to the industry in the shape of articles prepared for the information of the *general* public. The membership has shown a very good growth during the year.

The national highways were also favored by Mr. Gilchrist. "While we may not all consider the electric passenger car a touring car at the present time," said he, "nevertheless, we should all, I believe, take an intelligent interest in the great national highways. Do not forget that the use of these highways may be found very important for commercial electric vehicles.

"The year has witnessed a considerable development in the various plans for selling electric vehicles without batteries," he continued, "giving battery service on some rental or battery exchange plan. It is perhaps too early to express an opinion as to the ultimate result of this movement. It is most important, and I do not hesitate to say that some plan of this sort must be worked out to a successful conclusion before the electric delivery wagon or truck is to be regarded as an entire success for the use of the small merchant. The large user has a great success with the electric wagon at the present time, but it seems to me that we must certainly extend a helping hand to the small user in the matter of battery maintenance.

The Garage and Rates Committee reported that early in this year a meeting was held in Chicago to which the representatives of all of the commercial vehicle manufacturers having offices in that city were invited. At this meeting the representatives expressed an unanimous opinion that:

1. A battery service system would make it possible to increase their sales 100 per cent in the district where a suitable service was available.

2. If the battery service could be rendered through independent reliable garages it would be preferable.

3. That more sales effort must be spent

on prospects. At present in this district there are thirty gas truck salesmen to one electric.

Recommend New Sign

This committee has recommended a new sign which measures 24 in. across and has a blue background with a red cross-bar and letters of white. The wording is "electric charging station."

C. E. Smith of the Walker Vehicle Co. spoke on the results so far attained and the experience gained by his company by the new scheme which the concern has adopted in Chicago of renting batteries, selling the cars without them and at a reduction. He outlined the plan of giving the electric garage dealer the benefit of the battery plan, and said that it has been a great stimulation to sales of these cars in the Chicago territory. It enables them to sell the cars at a lower first cost, and then there is a fixed monthly rate for battery rental and charging.

W. H. Conant asked if there are any mileage limitations on the scheme, or where the car is run, or who operates it. He also wanted to know if the condition of the car made any difference in the rental charge. His idea is that the contract should not ignore accidental injury, nor should there be a definite rate for current when cars are run so differently as regards total distance by different people. He questioned as to who is responsible if the car is damaged and the battery hurt, and wondered if it is good business to sell an article of a definite life on a partial or deferred payment plan.

Central Station Co-operation

The report of the committee on central station co-operation was received with a great deal of enthusiasm by the convention, dealing as it does with a subject so vital to the interests of both manufacturers and those who supply current.

George H. Kelly had no written paper to present in attacking his subject of the "Problems We are Facing and How They May Be Met," but he electrified the convention with some most appropriate and rapid-fire extemporaneous logic.

Co-operation Is Better

The past year has shown marked development in the co-operation between the different branches of the electric vehicle industry, Mr. Kelly stated. There are two questions before the industry. One is the creating of a demand, and the other is how to care for the cars after they are sold. The electric car of to-day is a vehicle of utility and service, and not to do stunts with, he said. For city use, the electric answers the question of transportation and utility for 99 per cent of the users to-day. Its possible speed is in excess of the speed limits of any city in the country, and its mileage is greater than anyone requires. The people, according to Mr. Kelly, are beginning to realize more and more that the electric is a preeminent town car.

He says that the big problem is how to prove this to the great majority of the people, and he believes that educational publicity is best. But the members of the industry must be absolutely convinced themselves first. If there were enough of the vehicles manufactured absolutely sold on the great saving of electric trucks, and they would convince the buying public, there would not be enough electric truck makers to meet the demand.

Care A Problem

The other big problem is the care. Mr. Kelly says all must admit that the electric car is unable to get the expert care that the gasoline vehicle can get to-day. In order to be assured of proper electric care, one must go to an educated electric man. There are not over a dozen electric garages of merit in Cleveland, for instance, while there are over 150 gasoline garages, according to Mr. Kelly. It is easy enough to sell the cars, he says, but it is difficult to keep them sold and to get repeat orders under existing service conditions. He emphasized the point that all must make sure of the facilities for care of the cars, and that is where the central station people can be of greatest assistance—in co-operating with the manufacturers. He thinks the new battery service schemes are going to have a tremendous helpful influence. He has already noticed the impetus given the business due to them.

The wise car buyer of to-day, says Mr. Kelly, is not so much interested in the first cost as he is in the operative cost, and battery care is the big problem from this standpoint.

Speaking of the electric taxicab, Mr. Kelly said that as an advertisement it is the greatest thing that the electric vehicle business has ever had. In five years he predicts that the electric cab will so far outnumber any other type that the other will be almost forgotten.

Touching upon the 10 to 15 per cent price reductions of all electric vehicles during the past year, Mr. Kelly emphasized the fact that the reductions are absolutely dependent upon the market to make a dollar. The manufacturers must have the production to make money. They cannot compete in price with the low-priced gasoline car, he says, and the great problem for all is to get together and get more soul into the business.

—

Northwestern Motor Co. at Pottstown

POTTSTOWN, PA., Oct. 21—The Northwestern Motor Co., this city, will lease space in a local plant to manufacture a motor. New York capital is back of the company and will send here part of the equipment of the Hazard Motor Co., Rochester, N. Y.

Lavine Gear Co. Is New Name

—

Co. Reorganized and Capacity To Be Doubled—H. A. Uihlein, of Schlitz, President

RACINE, WIS., Oct. 23—The Lavigne Gear Co., Racine, Wis., one of the most extensive manufacturers of steering gears for pleasure and commercial vehicles in the United States, has been reorganized and has put into effect an extension program which will practically double its capacity. The name of the corporation has been changed to Lavine Gear Co., to simplify pronunciation. Officers are: President and treasurer, Herman A. Uihlein, Milwaukee; vice-president, P. B. Wohlrab; secretary, D. L. Robertson; sales and advertising manager, E. M. Caskey. Mr. Uihlein is a member of the well known Uihlein family of Milwaukee, owning the Schlitz brewing interests. Mr. Wohlrab was for several years production manager of the Lozier Motor Car Co., Detroit, Mich., and Plattsburg, N. Y., and also formerly master mechanic of the Maryland Steel Co. Mr. Robertson was for ten years with Crerar, Adams & Co., Chicago, in charge of purchasing and orders. As secretary, Mr. Robertson will be purchasing agent and office manager of the Lavine company. Mr. Caskey formerly was engineering sales manager of the S. F. Bowser Co.'s Western division.

The Lavine company is experiencing a greatly increased demand for its products from both foreign and domestic sources and is enlarging the shops and installing much new equipment to accommodate the demand.

—

Woods Mobilette Buys International Cycle-Car and Accessories Co.

CHICAGO, ILL., Oct. 23—At meetings of stockholders of the Woods Mobilette Co., and the International Cycle-Car and Accessories Co., held about two weeks ago, action was taken whereby the Woods Mobilette Co., purchased the entire business, assets and good will of International Cyclecar and Accessories Co.

The latter company will, therefore, pass out of existence entirely just as soon as the necessary legal requirements can be complied with.

—

Automobiles Cut S. P. Earnings

NEW YORK CITY, Oct. 25—The Southern Pacific Co., in its annual report states that automobile traffic during the past year made big inroads on its earnings. About two-fifths of the $8,600,000 loss in operating revenue, was due to passenger traffic in automobiles.

Zimmerschied Tells Safety First Men of Engineers' Contribution

Advocates Standard License Plates and Methods of Attaching, Standard Gearshift Gates, Location of Engine and Car Numbers and Anti-Glare Provision for Headlights

DETROIT, MICH., Oct. 22—On the second day of the Safety First Federation of America's convention, the two most important matters discussed were the model street traffic ordinance suggested principally by John Gillespie, Police Commissioner of Detroit, and the suggestions made by Chairman Karl W. Zimmerschied of the standards committee of the Society of Automobile Engineers, on the Contribution of Automobile Engineers to the Movement of Safety First.

Among the principal provisions in the ordinance is the one providing that the driver of any automobile must be licensed, owner or chauffeur, and that his minimum age be sixteen years, and that he be free from any physical ailment which possibly might affect him from properly handling a motor car. Special attention should be given to intoxicated drivers, who, when discovered, should have their license taken away.

Briefly stated the ordinance provides for:

1. Education and special instruction of policemen before assigning them to traffic duty.
2. Standard code of hand signals to be used by traffic officers.
3. Fixed locations for traffic officers at intersections to be distinctly marked.
4. Elimination of glare of head and side lights.
5. Use of muffler cut-outs to be prohibited.
6. Standardization of left-hand turns at intersections.
7. Near-side stops for street cars.
8. Rear lights on all horse-drawn vehicles.
9. Elimination of steps on all horsedrawn and motor trucks.
10. Standard color, size, design, and means of attachment for all street traffic signs, including school, hospital, church, safety zones, fire hydrants, railroad and street railway crossings, alley, mail box, playground, crosswalks, parking, etc.
11. Designation of safety zones and crosswalks as embodied in the Detroit plan of painting.
12. Education of the public to use crosswalks at intersections and authorizing police departments to control pedestrian travel as provided in section 2 of the Detroit traffic ordinance.
13. Standard traffic ordinance and code of regulations for adoption by all cities.
14. Licensing of drivers or operators of all motor vehicles.
15. Exclusive use of siren whistles on police and fire whistles.
16. Standardization of accident reports by municipalities.
17. Chain guards on vehicles driven by the side chains.

Most of these provisions were discussed previously by the traffic committee at its meeting held June 4 in Detroit.

Speaking as chairman of the standards committee of the Society of Automobile Engineers, Karl W. Zimmerschied suggested four regulations which he believes will help the safety first movement a great deal. These suggestions are:

1. Standard license plates and methods of attaching them.
2. Standard gearshift gates or progression.
3. Standard location of engine and car numbers.
4. Anti-glaring provision for headlights.

In the course of his address, which was entitled "The Contribution of Automobile Engineers to the Movement of Safety First," Mr. Zimmerschied spoke as follows:

"It goes without saying that the very first concern of the automobile engineer in his individual capacity as a designer is the securing of increased dependability in the finished vehicle; especially in such details as steering and braking mechanism, commonly known as the control.

Improvement in Design

"Better steels, properly treated and used in adequate sections, are now the rule rather than the exception in such vital parts as axles, steering knuckles, reach connections and brake rods. Brake bands are lined with better materials than formerly, mounted so as to have the maximum life and holding power. Spring suspensions have been redesigned so as to make the car 'hold the road' better than formerly, and the center of gravity of the whole car has been lowered so as to decrease skidding and to lessen the liability of the vehicle to capsize.

"There is little or no mechanical advantage to be gained by locating the steering column either on the right or left, but the majority of engineers have adopted the left hand drive largely in the interest of the driver's safety, since this position decreases the chances of collision.

Standard Location for Numbers

"Taking the last first, the committee has adopted a standard position for car, chassis, and engine numbers so that police departments can identify vehicles with the minimum of trouble and loss of time. It recommends that the car number be indented in the right frame member, as near the spring horn as possible.

"The engine number shall be on the crankcase, as far forward as possible, on top and as near the middle, crosswise, as possible, preference to be given the right hand side. This ought to act as some deterrent against the stealing of cars, and certainly will be of great benefit in restoring cars that have been stolen.

Standard License Plates

"Standards for the details of license plates, with recommendations designed to secure greater legibility and more adequate lighting of the same have passed the standards committee and are ready for final action by the society. We wish to lay considerable stress upon these standards, calling the attention, especially to those who have any influence in legislation to the great desirability of obtaining uniformity at least with respect to methods of affixing license plates throughout the various States.

"The maker's interest begins with the necessity for providing a standard bracket for attaching these plates; as long as almost every States uses a different size and shape, it is evident that the designing of a bracket which will accommodate all plates is exceedingly difficult, if not impossible.

"Many of the present brackets are either useless in themselves or require annoying operations on the part of the final user in order to attach the plates at all.

Standard Gearshift Gates

"One of the cardinal principles of safe driving is of course that all the manipulations necessary to control a car should be performed by the driver as a matter of unconscious habit. Steering, braking, accelerating, and shifting of gears must come as natural as walking, and in attaining this end, especially in the case of those who have to drive more than one make of car, the standard provisions for the control are of the greatest importance. The location of the clutch pedal on the left and the service brake pedal on the right has become practically universal; the successive positions through which the gear shifting lever has to go in progressing from one speed to another have been standardized by the society and are closely followed by the majority of cars using selective transmissions.

"It is most disconcerting to a driver who has become used to one of these standard progressions to try to drive a car with any other order, so that the society is using all its influence to obtain adherence to the preferred form.

"The accelerating pedal is sometimes located between the other two control pedals and sometimes to the right of both; it is not unusual for a man in a strange car to depress the accelerator pedal instead of the brake pedal and it is therefore desirable that this location should be standardized also. Some throttle and spark levers are opened or advanced with a counter-clockwise motion—often the opposite is the case. As in the case of accelerator pedals this practice should be unified also."

New York S. A. E. Talks Metallurgy

Hears That Recrystallization Is Non-Existent and Sees Movies on Tube-Making

NEW YORK CITY, Oct. 22—At the regular October meeting of the Metropolitan Section of the Society of Automobile Engineers held at the Automobile Club of America last night two lectures on metallurgical subjects were given. Prof. William Campbell of Columbia University made an address on the elements of metallography and C. F. Roland of the metallurgical department of the National Tube Co., delivered a lecture on steel tubing from ore to tube accompanied by three reels of motion pictures showing the progressive stages of manufacture from the time the ore is taken from the ground until the tube is finally stamped with the nameplate of the manufacturer.

Professor Campbell's talk brought out the difference between the chemical analysis method of determining the qualities of the steel and the newer and rapidly growing method of determining the merits of material by its structure under the microscope. The lecture was accompanied by a series of stereopticon views showing photo micrographs of different classifications of material. The granular structure of the metals was illustrated and the pith of the address brought out clearly how the inter-relationship of the granules determined the strength of the material, and its ability to resist various kinds of stresses.

Recrystallization a Myth

One of the most important points brought out in the address was the non-existence of the so-called re-crystallization which many engineers still believe to take place when the metal becomes fatigued. Professor Campbell illustrated by the photo-micrographs thrown on the screen that these so-called crystallization fractures are nothing more than breaks due to the development of a weak spot, caused by the action of one grain upon another, thus breaking up the closely knit structure necessary to strength. The distorted area of the metal loses its strength and the piece fails when the section has been reduced to such a degree that it is stressed to the ultimate.

The lecture by Mr. Roland was of an explanatory nature dealing with the subject shown by the three reels of motion pictures. The first picture shown, illustrated the prospective process of drilling the ground and then forcing by means of a stream of water samples of the ore to the surface. If the ore thus found is sufficiently rich in iron, mining operations are started. The next step shown was the removal of the useless surface dirt and then the giant steel grab buckets, which pick up practically a ton of ore at a time and place it into the waiting ore cars in long trains of which it is conveyed to the coke fields where the blast furnaces are located. It is cheaper, Mr. Roland explained, to bring the ore to the coke, than it is to bring the coke to the ore, and since coke is necessary in the manufacture of pig iron, all the ore is transported first by car and then by lake steamer in this instance, to the coke fields.

The products of the blast furnace or the pig iron is refined into steel and the billets are rolled into longer billets and finally into skelt, or plating from which the tubing is manufactured, either by the butt welding process or the lap welding process. The two methods, as the names imply, indicate the manner of joining the ends of the plate in fastening the tube. In the butt welding the ends are brought together end to end and the weld completed while in the lap welding, one end is brought over the other and hammered into position at forging temperature. The pictures illustrated the rolling and welding operations step by step and finally showed the inspection of the finished tubes and the methods of testing.

Testing the Quality

Portions of the end of each tube are cut off and submitted to bending and flanging tests to determine the quality of the material and the efficiency of the weld. Tubes such as those used in boilers, or for other work where a high degree of strength and reliability are necessary, are clipped at both ends and subjected to a double test. Throughout the entire series of films, the audience was impressed by the great amount of automatic electric machinery employed and the absolute uniformity which seemed to be secured from the time that the ore left the mines, until the tube was ready for shipment from the huge mills.

—

Detroit S. A. E. Publicity Committee

DETROIT, MICH., Oct. 25—A publicity committee for the Detroit Section of the Society of Automobile Engineers has been appointed by chairman George W. Dunham of the section. The members are: H. W. Ford, chairman; Lee Olwell, K. W. Zimmerschied and J. C. Weed.

—

Ward Electric Shows Economy

NEW YORK CITY, Oct. 21—The Ward electric delivery car which left this city for Clevelend on Oct. 6 and arrived in the latter city on Oct. 17, covered the 733.8 miles with a total current consumption of 1564 amp.-hr. Only twenty-five charges of the battery were necessary.

Army Wants Motor Ambulances

Surgeon General Orders Convening of Board to Select Type—Horses To Stay

WASHINGTON, D. C., Oct. 23—Acting under the belief that the time has arrived when there may be greater dependence upon motor transportation as ambulances and for for field sanitary units, the surgeon general of the army has directed the convening of a board for the purpose of ascertaining what type of automobile ambulance it is desired to adopt for the use of the medical department. The board is composed of Major A. W. Williams, Captain Percy L. Jones and Captain Arthur W. Christie, and all of the medical corps on duty in this vicinity.

There are about twenty automobile ambulances now in the service, all of them equipped with the standard ambulance body. Department officials point out, however, that this does not mean that there will be dependence upon motor transportation for the medical department to the exclusion of the animal-drawn vehicle, which is destined, they say, to remain of practical use in certain places where the motor vehicle cannot be used to advantage.

—

Propose Changes in Bay State Automobile Laws

BOSTON, MASS., Oct. 22—The Massachusetts Highway Commission is now making preliminary notes on what recommendations it will present to the next Legislature on motor topics, and one of the principal requests will be to have the law changed so that the initial suspension of a driver's license when convicted of operating recklessly or under the influence of liquor will be lengthened from the present period of 60 days to several months or a year.

"The board will also advocate again, no doubt a flat rate of 25 miles an hour on the State highways," says Commissioner James D. Synan. "Something should be done toward uniformity in the matter of city and town regulations, and the board will welcome some such legislation. Now there are so many conflicting regulations that drivers do not know where and how to proceed through some of our cities and towns without breaking a law. When this is done the number of accidents should be lessened. Our board is doing its share to try to lessen them by our suspensions and making people who have had accidents submit to an examination as to fitness sometimes, together with requesting those who drink to sign a pledge not to drive after drinking.

$74,000,000 Exports in 1915

Increase Over 1914 Is $36,000,000—Trucks Gain and Passenger Cars Lower

WASHINGTON, D. C., Oct. 23—A statement issued by the Department of Commerce says that American automobile manufacturers doubled their sales abroad last year, their exports of automobiles and parts thereof in the year ending June 30, 1915, having aggregated over $74,000,000, against $38,000,000 in 1914, $2,000,000 in 1904 and $1,000,000 in 1902, the first year of record. The gains were most pronounced in the second half of the fiscal year, and if the record made by July is maintained until the end of December, which seems probable from present indications, the total exports of automobiles in the calendar year 1915 will be well above $120,000,000.

All parts of the world are buying American motor trucks and passenger automobiles, about eighty different countries being represented in the year's sales. Our motor trucks are being sold most largely in England, France, and Russia. In Greece, Denmark, Sweden, and Servia sales have also reached unparalleled proportions. Increased sales are likewise being made in many countries far removed from the war zone, including Canada, Cuba, Central America, Java, Australia, British South Africa, and in our own territories of Hawaii, Porto Rico, and Alaska.

The year's exports of passenger automobiles were slightly less than those of 1914. Large gains in exports to the United Kingdom, Asiatic Russia, Cuba, Central America, the British West Indies, British Guiana, Venezuela, and British East Africa were more than offset by decreases occurring elsewhere, notably France, Germany, and various countries in Europe, South America, and Asia.

The constituent factors in the automobile export trade for the last two fiscal years are as follows:

Value of—	1914	1915
Commercial automobiles	$1,181,611	$39,140,682
Passenger automobiles	25,392,963	21,113,953
Automobile tires	3,505,267	4,963,270
Automobile engines	1,391,893	1,405,334
Automobile parts	6,624,232	7,853,183
Total exports to foreign countries	$38,095,966	$74,476,422
Total to Alaska	68,435	91,381
Hawaii	1,285,258	1,514,585
Porto Rico	686,906	775,879

A complete record of the United States export trade in automobiles is contained in the table which follows. It shows the number of automobiles of each class exported to the different countries in the fiscal years 1914 and 1915 and the value of the exports in the latter year, expressed in thousands of dollars.

Exported to—	MOTOR TRUCKS Number 1914	MOTOR TRUCKS Number 1915	MOTOR TRUCKS Value 1915	AUTOMOBILES Number 1914	AUTOMOBILES Number 1915	AUTOMOBILES Value 1915	PARTS Value 1914	PARTS Value 1915

Note—The shipments to American territories included: Hawaii, 864 automobiles valued at $972,000; Porto Rico, 548 valued at $433,000; Alaska, 59 valued at $80,000 in fiscal year 1915.

Multibestos Maker Buys Former Walpole Plant

FRAMINGHAM, MASS., Oct. 23—The Standard Woven Fabric Co., this city, maker of Multibestos products and rubber specialties, has purchased the entire plant formerly operated by the Walpole Tire & Rubber Co. at Walpole and will take possession about Dec. 1. This plant will be used for the making of the company's own asbestos yarn sent direct to it from its asbestos mine. Part of the plant will be used for the manufacture of mechanical rubber goods, friction tapes, splicing compounds and other products.

F. J. Gleason, formerly of the Walpole company, will be in direct charge of manufacturing.

Anderson Rolled-Gear Plant in New Hands

TOLEDO, OHIO, Oct. 25—The Shaw-Kendall Engineering Co., this city, has signed a contract to take over the plant of the Anderson Rolled Gear Co. of Cleveland, and will manufacture the patented gears controlled by the Cleveland company. The Cleveland plant at which the experimental work has been done will be moved to Toledo, where the local concern will employ 1000 men within a year.

Columbia Commercial Car Moves

PONTIAC, MICH., Oct. 26—The Columbia Commercial Car Co., which is to locate here, is bringing its machinery from Kalamazoo, Mich., along with an order for fifty trucks to be delivered at the earliest possible date. Work will be begun at the local plant within a very short time.

Reo to Add 10-Acres Floorspace

Plans to Partially Construct and Assemble Most 1915-16 Output in New Plants

LANSING, MICH., Oct. 26—The Reo Motor Car Co. is constructing new buildings and additions which will add between 10 and 11 acres of floorspace to the plant, and work is being rushed that the additional space may be utilized at the earliest possible moment. It is planned to partially construct and assemble most of the 1915-1916 output in the new building space.

It is believed that within the next month the addition to the engineering building will be completed. The new building is three stories, of fireproof construction. The assembly room and body room will have double the present floorspace, as will the machine room on the second floor. The blueprint room will be located in the new structure and the old blueprint room will be given over to the drafting department.

With the completion of the addition the company will make its own photographs. The studio, which will be located on the third floor, will have ample space for the showing of complete cars and allow various views to be taken.

The following departments will be enlarged with the completion of the addition: Designing, drafting, machine shop, body engineering, body finishing, chemical, physical and motor testing.

One of the largest buildings will be the new receiving warehouse, which will be of brick, three stories, 52 by 121 ft. A Grand Trunk railway spur already has been laid to this location which is east of Platt Street and north of the other Reo buildings, and the contract calls for a 20 ft. receiving dock along this spur. A basement under the building will be used as a general stock storage room, as will the first floor. The second floor will be utilized for body and paint storage and the third floor will be used as a repair storage room.

New Truck Plant Largest

The largest building is the new truck plant which will be 667 by 250 ft., one story. The foundation of this building has been completed, and work is being rushed on the placing of the new steel windows and the erection of the walls. According to R. H. Scott, vice-president and general manager, it has not been decided whether the truck plant on North Grand Avenue will be discontinued with the completion of the new building or whether both will be operated.

Work on the new building at Baker Street and Washington Avenue, which joins the newly-erected assembly building, practically has been completed, and a portion of it already is in use. This building is of steel construction, 126 by 292 ft., three stories and basement, and will be used in the various assembling operations.

The present stock receiving room is undergoing the addition of two stories, and the excavation for the new Reo clubhouse is practically complete.

—

Detroit Steel Products Celebrates Record Breaking Business

DETROIT, MICH., Oct. 22—Officers and heads of department of the Detroit Steel Products Co. were entertained at a dinner given them by General Manager J. G. Rummey, at the Detroit Athletic Club. The reason was to celebrate the record-breaking business of the company. Practically all departments are working overtime and with night shifts. In the spring department there are three shifts and there is a 24-hr. working schedule. An average of 720 springs are turned out a day.

—

Chalmers to Add Again

DETROIT, MICH., Oct. 22—Further additions to the plant of the Chalmers Motor Co. have been decided upon, although several new buildings were completed only during the last few days. The new building now contracted for will be a four-story structure, 60 by 200 ft. to be used as machine shop and stock room. It will provide about 50,000 additional square feet of floorspace.

The convention hall is completed and will be inaugurated in conjunction with the annual Chalmers dealers convention, which will be held Nov. 15 to 17.

—

Strike at General Vehicle Plant

NEW YORK CITY, Oct. 21.—Machinists in the plant of the General Vehicle Co. plant in Long Island City to-day went on strike in sympathy with the strikers at the Schenectady plant of the General Electric Co., of which the General Vehicle Co. is a subsidiary.

It is stated that the strikers, numbering from 250 to 600, will not return until the 48-hr. week and other concessions which they asked for are given their fellow-workers at Schenectady. About 40,000 men are employed in the General Electric plants throughout the country.

—

Peerless Employees Strike

CLEVELAND, OHIO, Oct. 22—One thousand employees of the Peerless Motor Car Co. went on strike to-day. The strike comes because demands for the 8-hr. day and other concessions had been refused.

50,000 Model 83 Overlands

Motor of New Series To Be Block Type—Upholstery of Fabrikoid

TOLEDO, OHIO, Oct. 25—To date 50,000 model 83 Overland cars have been sold at $750 in touring form and $725 as roadster. Beginning the first week in November, shipments of the second series of 50,000 will be commenced by the Willys-Overland Co.

Several changes have been made in the model for this second series. Instead of having a motor with separately cast cylinders the power plant will be of the block type, with inclosed valves and removable cylinder heads. The bore and stroke remain the same, 4⅛ by 4½, also the five-bearing crankshaft. Another change is to be found in the upholstery. Instead of cloth, Fabrikoid will be used. Otherwise the cars will be identical with those of the first series.

—

Franklin Adds Three Buildings

SYRACUSE, N. Y., Oct. 25—The H. H. Franklin Mfg. Co., this city, has now under way additions which will increase its floorspace about 33 per cent. The additions will cost approximately $500,000 when finished and will bring the total floorspace up to 10½ acres.

The first additional unit consists of a two-story building with basement, that will be devoted exclusively to the die-casting department, with a capacity of 5,000,000 die castings annually. This is now practically ready for occupancy.

The second unit, a two-story saw-tooth building, will be used for a machine shop, experimental department and chassis tests, furnishing 24,000 sq. ft.

The last addition will be six stories high and will represent approximately 136,000 sq. ft., costing $200,000. It will be equipped about the first of 1916 and will be the largest plant in Syracuse when made a unit with a companion building already in use, according to the company.

—

Crowther Plant Nears Completion

ROCHESTER, N. Y., Oct. 24—Construction is rapidly progressing on the building being erected for the Crowther Motor Co. at Ridgway and Woodrow Avenues, this city. The first unit of what is ultimately intended to be a large plant is 145 by 150 ft., with a concrete floored shipping platform 20 ft. wide. The building will be completed for occupancy by Dec. 1. The company will manufacture a low-priced runabout, touring car and light delivery wagon, featuring the roller friction drive developed by C. E. Duryea.

Finds Prosperity Gaining in West

Studebaker Man Impressed by Widespread Improvement of Conditions in West

DETROIT, MICH., Oct. 23—"From my observations during my recent visit to Studebaker distributors throughout the Middle West and Southwest, there seems to be no possible doubt that we are at the beginning of the most prosperous period in the history of the country." This is, briefly stated, the way George L. Willman, assistant sales and adveritsing manager for the Studebaker Corporation, expressed himself upon his return.

"What impressed me most is that the condition of prosperity is general. Formerly we had cases of great prosperity in one or several states and either a stationary condition, or even a less healthy condition in other states. From what I have seen, and from what I hear from every one, the condition is general throughout the country. All through the corn belt reports are the same, namely, that the crops of this year are the best ever produced. Throughout the cotton region, although the production as to quantity is not as heavy as formerly, it will, however, be of greater money value and there will be no overproduction. The fruit crop, apples especially, I hear, will be one of the best ever seen. The farm products are good all around and the farmers have been getting more for them. In the mining districts prosperity is greater than at any time the oldest settlers can recall.

"This all means that the automobile industry will still further benefit by the general conditions.

Russell Has $2,000,000 Orders

MONTREAL, QUEBEC, Oct. 21.—The annual meeting of the Russell Motor Car Co. will be held in Toronto on Oct. 28. The total orders on the company's books for the new year opening Aug. 1, 1915, amounted to $2,000,000. The report, summing up the present position of the company, says: "The past two years have been most trying to your board. Without attempting any forecasts for the future, they feel justified in stating their belief that the working out of the business at present in hand, together with that to be secured from the regular branches of the company's operations, will enable them to meet their problems and assure the shareholders of the successful carrying on of its operations."

The results of the two years, as indicated in the profit and loss account, show a deficit of $741,670. The loss for the first year was $356,223 and for the second $140,388.

The company has few new cars or second-hand cars in stock. The program for this year contemplates the sale of two models, the Knight 32 and a lighter, smaller car than any yet produced by the company. It was deemed advisable to sell the company's business in Australia, payments for which will extend over a number of years.

Gray & Davis Increase Capital

BOSTON, MASS., Oct. 23—Because of constantly increasing business and heavy orders recently received, Gray & Davis, Inc. have enlarged the capitalization of the company from $1,750,000 to $2,000,000. A new issue of capital stock amounting to $250,000 has been authorized.

Market Prices Steady

NEW YORK CITY, Oct. 26—With the exception of rises in a few of the metals, prices in last week's markets were steady. Trading was brisk in most of the markets. Lead featured the metals markets with a rise of 25 cents per 100 lb. Copper was weaker, due to the demoralized foreign exchange situation. A fair business in copper was booked yesterday at 17¾ cents a pound. Tin was steadier and active with good trading in spot. The market yesterday went up to $33.63, a net gain of 38 cents for the week. Aluminum, with a fair demand, went up yesterday to 53 cents for No. 1 ingot in ton lots.

Trading conditions in Up-River Para was a little more active last week. The prices remained unchanged throughout the week at 57 cents. The oils and lubricants markets, with the exception of a 2-cent rise in linseed oil, remained unchanged.

Olds Export Trade Gains

LANSING, MICH., Oct. 23—Since the beginning of its active campaign for more foreign business, which was started four months ago, the Olds Motor Works reports, that it has met with much success. At the beginning of July the concern had representation outside of the United States and Canada, in Porto Rico, Cuba and the Hawaiian Islands only. Now there are Oldsmobile dealers in Great Britain, Holland, Norway, India, South Africa, Japan, Australia and New Zealand, while arrangements are being made for the car to be handled in practically all other countries in the world. The export business has been exceptionally satisfactory, states Export Manager W. von Zimmermann, considering the high ocean freight rates and the prohibition act of the British Government against shipping tires on cars.

New Departure Elects Directors

BRISTOL, CONN., Oct. 21—At the annual meeting of the board of directors of the New Departure Mfg. Co., this city, held on Oct. 19, at which DeWitt Page was elected president, as reported in THE AUTOMOBILE last week, F. P. Furlong, vice-president, C. T. Treadway, treasurer, and A. C. Hitchcock, secretary, the following directors were also elected: DeWitt Page, C. T. Treadway, F. P. Furlong, C. F. Pope, E. R. Burwell, A. C. Hitchcock, T. G. Treadway. Mr. Hitchcock succeeds Mr. Page. The new directors are Mr. Hitchcock and T. G. Treadway.

Elect Baker, Rauch & Lang Directors

CLEVELAND, OHIO, Oct. 25—Filling vacancies in the board of directors, stockholders of the Baker, Rauch & Lang Co., at an annual meeting last Tuesday, elected J. H. Wade, W. J. Mather, D. Z. Norton, J. H. Kling and C. L. F. Wieber, Jr.

Milwaukee Jobber Lowers Grade of Gasoline in Price War

MILWAUKEE, WIS., Oct. 23—The Bartles-Maguire Oil Co., one of the largest independent jobbers of gasoline and other petroleum products in Wisconsin, has issued notice to its customers in Milwaukee that owing to the shortage of high grade crude oils, it can no longer sell straight run distilled 62 deg. gravity

gasoline to compete with the 59 deg. gravity sold by Standard Oil. In consequence, the company offers a new grade, designated 59 deg. gravity gasoline. The new scale of prices now in effect, is as follows:

Gravity	Filling Station (Cents)	Tank Wagon Delivery (Cents)	Tank Wagon, 100 Gals. Delivery or More (Cents)
59 degrees...	12.5	11.6	10.6
62 degrees...	13.5	13.0	12.0
65 degrees...	16.5	16.0	15.0
70 degrees...	19.5	19.0	18.0

It is expected that the other independent jobbers, four in number, will follow suit in order to make uniform the prices for fuel in competition with the Standard. Nearly 125 filling stations are operated by the jobbers in various parts of Milwaukee.

—

Gasoline Up in Indiana

CHICAGO, ILL., Oct. 23—The Standard Oil Co. of Indiana will advance the price of gasoline 1 cent to 12½ cents and to 11½ cents for 100-gal. lots. The price of refined oil will be raised ½ cent to 7 cents.

—

142,000 Tons of Rubber Predicted

AKRON, OHIO, Oct. 23—A Goodyear Tire & Rubber Co. expert states that the world's production of crude rubber for this year will reach 142,000 tons, a substantial increase over 1914. Of this, 75,000 tons will be used in the United States, and fully one-half of it will find its way to the rubber factories of Akron. The acreage of plantation or cultivated rubber has increased from 75,000 in 1905 to about 1,330,000 in 1915.

Plantation rubber now comprises about two-thirds of the world's output.

General Advance in Securities

—

Firestone Tire with 145-Point Rise Features Market—Motor Issues Strong

NEW YORK CITY, Oct. 25—Automobile securities last week closed with unprecedented gains, ranging from a fraction to 145 points. Tire issues, especially, showed unusual strength. Firestone Tire common which reached the high mark of 804 on Friday, closed the next day at 720 at a record gain of 145 points. This represents a gain of 460¼ points in the last six months. No early realignment of the stock is said to be contemplated. Excess earnings are to be devoted to extending the plant and not to big dividends, officials of the company state.

General Motors, after a 15-point drop, rose last week to 372, a gain of 46 points. Studebaker, Overland and Maxwell also showed substantial gains, there being a scarcity of these issues for sale. Chevrolet, stock, which will be ready for delivery Oct. 27, closed on Saturday at 125, a drop of 5 points. Studebaker common went up 27 points, Overland 11 points and Maxwell 13 points. The latter stock was one of the strong features of the market. It is expected that the earnings for the current year may be as high as 15 per cent on the common stock. It is understood that the company has more than earned the full year's dividend on the first and second preferred stocks in the first three months of the current fiscal year, so that all earnings for the balance of the year will accrue to the common stock.

Most of the tire issues showed gains. Kelly-Springfield common rose 32 points; Goodrich, 1½; Goodyear 2, and Miller Rubber, 7 points.

A majority of the issues in the Detroit markets showed gains. General Motors closed at 375 with a gain for the week of 60 points. Studebaker common rose 32½ points and Continental Motor, 20 points.

—

$3,000,000 Bearing Co. Formed

DOVER, DEL., Oct. 23—The Killian Roller Bearing Corp., has been organized to manufacture roller bearings. Its capital is $3,000,000. The incorporators are: H. E. Latter, H. P. Coffin, and C. M. Egner.

—

$250,000 Tire Company Formed

CLEVELAND, OHIO, Oct. 23—The Mason Tire & Rubber Co. has been incorporated with a capital of $250,000 to manufacture automobile tires and inner tubes, and other rubber articles. The incorporators are: D. M. Mason, M. B. Mason, Robert G. Berlekemp, W. E. Sexton and O. M. Mason.

—

Victor Rubber Capital $400,000

SPRINGFIELD, OHIO, Oct. 23—The capital stock of the Victor Rubber Co. has been increased from $150,000 to $400,000 to allow for improvements and additional equipment.

—

International on War Orders

PLAINFIELD, N. J., Oct. 23—The International Motor Co. has closed an order for 700 5-ton trucks for Russia.

N. A. A. A. J. Closes 4 Day Convention

50 Accessory Manufacturers Represented—Jobber and Manufacturer Defined

KANSAS CITY, MO., Oct. 22—The National Association of Automobile Accessory Jobbers, in which there are about fifty accessory manufacturers as associate members, concluded its four-day autumn meeting to-day with excellent results. Several trade abuses received attention and progress was made toward a better condition in the field of the jobber and manufacturer.

One of the important works was the compilation of a list of jobbers; there are 254 in the list, but it may be changed if the future develops a necessity for alteration. This will eliminate the dealer or would-be jobber who in the past has been able to secure a syndicate catalog or other credentials and has secured a jobbers' price from the manufacturer. These jobbers' prices, it was stated, have in many cases been used to cut prices under the legitimate dealer, the goods being sold to the consumer instead of being jobbed. Both jobber and manufacturer were defined as follows:

Definition of a Jobber

A jobber of automobile accessories is one who buys in bulk or quantity for re-sale to established retail dealers in accordance with established trade methods. It is required that the major portion of the business be wholesale, and that he maintain sufficient general stock to meet the requirements of his trade.

Definition of a Manufacturer

An eligible manufacturer is one who produces one or more accessories on which his policy is to establish a consumer's, a dealer's and a jobber's scale, does not solicit consumer's business and maintains his own scale to both dealer and jobber. Legitimate exceptions to be considered according to established customs of the trade conditions of each member.

Future dating was condemned as unbusinesslike and a burden on the seller, who by this practice is obliged to carry the obligations of the buyer for a term of months without compensation.

The syndicate catalog was condemned, despite the eloquent plea made on the floor by a representative of a Chicago catalog publisher. It was held that this catalog, which can be bought in quantities, by a jobber or dealer, is often used by a non-jobber to get jobber's prices. The jobbers agreed that the use of a general catalog of this description by all jobbers would submerge the jobber's individuality.

Especial condemnation was accorded to the syndicated catalog of some jobbers. The manufacturer is often, it was stated, held up for payment for the space occupied by his goods. This was aimed at one jobber in particular. The only relation between the manufacturer and such catalogs in the future will be the furnishing of standard electrotypes for use in their pages. No payment will be given for their use and no inserts will be furnished.

To Support Stevens Bill

The Stevens bill, which would permit the manufacturer to maintain prices on his goods, was discussed by G. A. Waddle of the Goodyear Tire & Rubber Co., and after his address the association went on record as in favor of it. Members elected to urge their congressmen to support it.

Mail order houses and leagues were placed under the ban and the members ruled that goods should not be sold to them. It was also voted that there is no field for purchasing syndicates.

The member who has legitimate branches will not be required to take out additional memberships for his branches.

The next meeting will be held in New York, Jan. 7 and 8 and 10 and 11, the last two days of the show and the first two days of the following week. The first two days of the meeting will be taken up by committee work and Jan. 10 and 11 by open sessions.

At this time the association will bring up the question of: What is a proper discount for the jobber? Figures given at the convention showed that it costs 17½ per cent to do business and that unless the jobber gets at least 35 per cent on his selling price he cannot make money. A seal and insignia are to be prepared.

Winter Business Problems

A valuable discussion centered around winter business, led by H. R. Williams of the Gibson Co., Indianapolis, a jobber, and William K. Norris of the McQuay-Norris Mfg. Co., St. Louis, a manufacturer.

Williams showed a curve of the business of three jobbers, which curve went away up in the summer and slumped far down in the winter. The overcoming of this difference is the problem.

Both manufacturers and jobbers agreed that winter business must be stimulated, and Williams proposed an installment repairs plan, which he said he and his salesmen worked with some success last winter. The salesmen went to garagemen in the smaller towns of the Middle West, where many of the garages close up in the winter, and urged the repairmen to get cars in for overhaul during the winter. The car owners paid for this work in monthly installments and the shop was kept busy. Incidentally this developed some business in accessories and supplies for the jobber; seventy garages, that would otherwise have closed, were kept open.

To Boom Winter Driving

Williams and Norris both recommended a propaganda in favor of the use of cars in winter. Manufacturers of cars have in some instances run advertising of this kind, the McQuay-Norris company itself has run some, and it was urged that every manufacturer of accessories and cars do likewise. There was laid out a wide field of operation for salesmen in missionary work of the kinds mentioned.

Following the sessions the McQuay-Norris Mfg. Co., took fifty members to St. Louis on a special train of Pullmans to be the company's guests in that city. The entertainment included an inspection of the factory, golfing, dinners and theaters.

—

Dixie Tourists on Florida's Sandy Roads

LIVE OAK, FLA., Oct. 20—Swaying over the wet, sand highways of Florida, the ten cars participating in the first inspection trip of the Dixie highway, covered 97 miles to-day in their run from Tallahassee to Live Oak, which is about half way between the capital of the State and the metropolis on the Atlantic seaboard.

The roads of Florida in this section of the State are several stages removed from boulevards, being composed mostly of sand with some short stretches of red clay. In dry weather the cars travel in deep ruts. When it rains hard, as it did to-day, the highways are a combination of sticky mud and water. Little provision has been made for drainage and for the greater part of the way the highways through the dense pine forests are too narrow to permit machines to pass. There are some places on the primitive trails where the tops scraped against the trunks of trees.

Reach Jacksonville

JACKSONVILLE, FLA., Oct. 21—For the first time since the Dixie highway tourists left Chicago and the shores of Lake Michigan fourteen days ago, the motorists gazed upon a large body of water this afternoon when Jacksonville, cooled by the breezes of the Atlantic Ocean, was reached after an arduous 87-mile trip from Live Oak, last night's stop.

The run across the northern counties of Florida, where the natives apparently are living a hand-to-mouth existence, was made over soft sand roads through which the cars staggered on low speed. An attempt had been made by the good road boosters of the section to make the going less tortuous by scattering pine needles, sawdust and pine shavings on the pristine trails through the turpentine

camps and practically untraveled swamp land.

Northern Florida does not lack good roads enthusiasm. This was evident all along the route and at every stop, where a rousing welcome was extended the tourists. This section of the State, however, is shy on funds and because of the small population, bonding the counties for any large amount is impossible. Baker County, for example, has 30 miles of Dixie highway, more miles than any other county through which the Chicago-Miami thoroughfare passes. But Baker County is 30 miles square and has a population of only 4,000, of which number but 500 are land owners.

—

Maxwell Makes Detroit to Indianapolis and Return in 20:1

DETROIT, MICH., Oct. 21—From Detroit to Indianapolis and return in 20 hr. and 1 min. for the 597.2 miles, is the run made by Ray McNamara, of the engineering department of the Maxwell Motor Co. in a Maxwell stock car. He was checked at the start and finish by W. D. Edenburn, local representative of the contest board of the A. A. A., while in the Indiana city the checking was done by Jack Baci, A. A. A. representative for Indiana. On the run to Indianapolis the 298.6 miles were covered in 8 hr., 58 min., or an average of 33 m.p.h. This run was 1½ hr. faster than the fastest railroad run. The start was made at 4.11 a. m. from the Maxwell headquarters on Woodward Avenue and McNamara reached Indianapolis at 1.09 p. m. After a stop of 14 min. he restarted and arrived here at 12.26 a. m.

Tom Orr also made a fast trip in another Maxwell stock car, although he was considerably delayed by a series of tire troubles en route.

—

Henney Buggy Will Build Bodies

FREEPORT, ILL., Oct. 23—The Henney Buggy Co., this city, will hereafter devote its plant largely to the manufacture of bodies for commercial trucks to be attached to Ford chassis. After a series of experiments, the plant has turned out a line of models to suit various industries, ranging from the small package box or open body that can be fastened at the back of the seat on the Ford runabout, to the large steel paneled-inclosed body that is used largely by clothing, dry goods, and laundry firms, the bodies ranging in price from $18 to $100 according to the requirements of the trade.

—

Master Carbureter on Owen

DETROIT, MICH., Oct. 25—The Master Carbureter Corporation announces that the Owen Magnetic Co., New York City, which makes the Owen cars, has contracted for Master carbureters as standard equipment.

Aluminum Alloy Piston for Fords

—

McQuay-Norris Mfg. Co. To Sell Set with Leak-Proof Rings for $30

ST. LOUIS, MO., Oct. 22—The McQuay-Norris Mfg. Co., this city, maker of Leak-Proof piston rings, has announced a die-cast aluminum alloy piston, completely equipped with Leak-Proof piston rings and suitable for Ford cars. The company has adopted a new alloy, a product of the French patented Cothias process, which is composed largely of aluminum and known to the trade as Lynite.

The conductivity of Lynite, it is stated, is calculated at three times that of cast iron and coefficient of friction is several per cent less than that of cast iron.

The company sells four Lynite pistons for $30. This equipment will be in the hands of jobbers throughout the country in the near future and can be had for Ford motors that have been rebored to 0.031 oversize.

—

Miller Aluminum Alloy Carbureter

LOS ANGELES, CAL., Oct. 19—Harry A. Miller, this city, has placed a new carbureter on the market known as the Miller. It is constructed of Miller metal, an aluminum alloy discovered while experimenting on a carbureter for military aeroplanes.

—

Aluminum Piston Ring Tried

LOS ANGELES, CAL., Oct. 24.—The Harry A. Miller Mfg. Co. has run a successful 12-hr. test of a new aluminum alloy piston ring in a motor with pistons also of aluminum. The new ring is a double, concentric pattern with light wall pressure and it is said that the effect of the run was merely to put a gloss on the surface of the rings.

—

15 per Cent Raise for Rubber Men

AKRON, OHIO, Oct. 25—About 1500 machinists employed by Akron rubber companies and allied industries were notified to-day that their wages would be increased 15 per cent. The increase is made voluntarily by the employers and adds about $1,000 a day to the income of local machinists.

—

Goodyear Sales Officials Meet

DETROIT, MICH., Oct. 22—A conference was held this week of the Detroit district sales representatives of the Goodyear Tire & Rubber Co. Business conditions and policies were discussed. Among the officials who were present were C. W. Martin, manager of the automobile truck department at the plant in Akron, Ohio; H. G. Palmer, assistant manager of the automobile tire department in Akron, R. S. Burnham, special manufacturers representative, R. H. Daniels, special sales representative from Akron; E. F. Jackson, district manager; C. W. Hockler, assistant district manager; W. A. Hazlett, city manager; Harry Ammon, assistant city manager; J. P. Kennedy, manager of the local truck tire department; J. D. Harding, manager of the electric tire department.

—

$10 a Week Buys a Ford

BOSTON, MASS., Oct. 23—What is claimed to be the first offer of its kind, a Ford club financed by the Dorchester Trust Co., has been started in Boston. It originated with Wilbur F. Beale, treasurer of the trust company, who worked out all the details and then began advertising it in the papers. The plans call for a person agreeing to deposit $10 a week with the trust company from now on for a period of thirty or thirty-five weeks depending upon whether a runabout or a touring car is wanted. The bank will pay interest upon the deposits, but those who enter the plan must agree not to withdraw any of the money until the time limit is up. Then if the depositor decides that he does not want a car he can have his money and the interest back. It will be paid over to him and he will be sent to a garage if he decides he wants a car and there he will get a new Ford machine. If he wants any extras put on there is a clause in the contract requiring the depositor to continue puting $10 a week in the bank until the extras are all paid for. If depositors prefer a more expensive car arrangements may be made later to carry along deposits for such a one.

—

Garford Men Study Worm Drive

PHILADELPHIA, PA., Oct. 22—Fifty owners and drivers of Garford trucks together with the Garford organization in Eastern Pennsylvania assembled at the salesroom and service station of the Garford Philadelphia Co., last evening, to study the construction and operation of the Sheldon worm gear drive axle used on the Garford truck. E. A. Shelly, advertising manager of the Sheldon Axle & Spring Co., discussed the salient points of worm gear constructions.

—

Manzel Pump Reduced to $15

BUFFALO, N. Y., Oct. 21—The price of the two-cylinder engine-driven tire pump made by the Manzel Bros. Co., this city, has been reduced from $20 to $15. This price will include all fittings ready for immediate installation.

To Make Trailers—The Lowell Cutter Co., Lowell, Mich., has added the manufacture of automobile trailers to its activities.

Timken Roller Bearing Adds—The Timken Roller Bearing Co., Canton, Ohio, is building an addition to its grinding room.

Beach Creek Co. Builds—The Beach Creek Auto Co., Beach Creek, Pa., will build a two-story factory. The estimated cost is $25,000.

Guide Motor Co. Adds—The Guide Motor Mfg. Co., Cleveland, Ohio, will construct an addition to its plant at Madison and West 114th Street. The estimated cost is $3,000.

Rutenber Adds—The Rutenber Motor Co., Marion, Ind., has contracted for the building of a third story to its plant, which will give the company 30,000 ft. more floor space and will increase its capacity 40 per cent.

McQuay-Norris Adds—The McQuay-Norris Manufacturing Co., St. Louis, Mo., maker of Leak-Proof piston rings, has purchased a tract just east of its present building at 2808 Locust Street and will begin the erection of an addition immediately.

Heron Adds—The Heron Mfg. Co., Utica, N. Y., will build a two-story addition, 85 by 150 ft., costing about $100,000. This will practically double its present working force. The company recently received a large order for the manufacture of a daily minimum of 4000 connecting rods for engines.

Milwaukee Engine Plant Started—The Milwaukee Auto Engine & Supply Co., 708 Winnebago Street, Milwaukee, Wis., has broken ground for its new factory and machine shop at Twenty-ninth Street and Meinecke Avenue. Work will be rushed so that occupancy may be taken early in December. The shop will cost about $15,000.

Hoosier Auto Parts Co. Incorporates—The Hoosier Auto Parts Co., Muncie, Ind., has incorporated with a capital of $100,000. The company is putting its plant into first class condition and operations are expected to commence the manufacture of parts for clutches, universal joints, etc., as soon as conditions will permit. A service department will be maintained for supplying repair parts on jobs formerly turned out by the B-T-K Gear & Engine Co., the plant of which was recently bought by the Hoosier company at a receiver's sale.

F.-W.-D. Adds—The Four Wheel Drive Auto Co., Clintonville, Wis., will enlarge its headquarters and add to its equipment. A new stock room 46 by 120 ft. is being built. A number of new heavy duty turret lathes, milling machines, boring bars and drill presses are being installed. There will be a new machine section, 54 by 120 ft. A new heat treating and tempering room, 20 by 40 ft. This latter room is completed. The company has just completed a building entirely separate from the plant. This building is entirely of steel, is fireproof, and will be used for the storage of oils, grease and paints.

Wallis Tractor Plant to Move—The plant and headquarters of the Wallis Tractor Co., Cleveland, Ohio, owned principally by Racine, Wis., capital, will be moved to Racine by the end of October. The concern was organized about eighteen months ago by H. M. Wallis, president of the J. I. Case Plow Co., Racine, whose son is the designer of a farm tractor. A plant was established at Cleveland, in charge of the son. It is now desired to concentrate production t Racine, and a large part of the former Racine-Sattley Co.'s Racine works have been leased as a permanent home for the tractor company.

Kellar Tool Busy.—The Kellar Pneumatic Tool Co., South Brooke Street, Fond du Lac, Wis., specializing in the manufacture of special tools, dies, punches and similar tools for manufacturers of motors and motor vehicles, has been obliged to put on a night shift to accommodate the extraordinary demand. According to Julius Kellar, Jr., general manager, the company has enough orders from one motor car manufacturer alone to keep the plant taxed to capacity night and day until the ened of the year. Mr. Kellar also said that during the last four or five months the company has turned down from $2,000,000 to $3,000,000 worth of war business.

Milburn Electric in Hartford — The Thomas A. Stewart Co., 69 Pearl Street, Hartford, Conn., has been appointed distributor of the Milburn electric in Hartford, Tolland, Litchfield and Middlesex counties. P. A. Wainwright of Hartford has been placed in charge of the automobile department. Temporary vehicle quarters have been secured in the Cole Service station at 67 Mulberry Street and later the company will be located in the remodeled Heublein garage. This is the initial appearance of the Milburn in this section of the State.

New Delion Tire Sub-Agencies—The Delion Tire Sales Co., 203 Allyn Street, has appointed the following sub-agents: W. E. Luettgens, South Manchester; H. H. O'Neil, New Britain; the B & S Tire Repair Co., Middletown.

Late Ohio Trade News—E. T. Paul, 123 Parsons Avenue, Columbus, Ohio, has taken the central Ohio agency for the Quaker line of tires.

The Cott-McKelvey Company, 448 North High Street, Columbus, has opened a service and repair department in conjunction with the Pullman and Jackson agencies.

The Griswold-Sohl Co., Columbus, has purchased the stock of Harry E. Smith, automobile dealer at 43 West Broad Street,which will continue the business at present at the same location. Later on the stock may be moved to the Griswold-Sohl Building.

Spokane News—The C. H. Hornburg Co. has moved into new quarters at 1421 Second Avenue. It will continue to handle the Regal line.

The latest addition is the Oldsmobile Co., incorporated for $50,000, and composed of G. K. Marsh, F. M. Marsh, Henry Madigan and R. L. Strickie. This company will distribute Oldsmobile cars in eastern Washington, except three counties south of the Snake River, and all of northern Idaho. Headquarters are at 2122 Walnut street.

Opens Portland Tire Shop—G. M. Thomas, inventor of a stretchless inside tire, with stores in Los Angeles and San Diego, Oakland and San Francisco, Cal., has opened a tire shop at 82 Broadway, Portland, Ore.

Seattle Truck Co. Moves—Gerlinger Motor Car Co., distributors of Federal trucks, have moved into its new home, 2319-23 Fifth Avenue, Seattle.

Late Louisville News—Robinson Bros. & Co., 609 West Main Street, has acquired the agency for the Globe tire.

The Paige Motor Sales Co., 725 South Third Street, Louisville, Ky., has secured the agency for the Grant in the Louisville territory. This concern also handles the Paige.

The Breyfogle-Green Co., 1600 South Second Street, has secured the agency for the Allen.

The Louisville Auto Top Co. has opened an office and shop at 304 West Breckenridge Street. The concern, of which R. P. Bottorff is the manager, will make a specialty of auto trimming.

The National Auto Sales Co. will move on Oct. 15 from 728 South Fourth Street to 931 South Third Street, the former location of the Louisville branch of the Ford Motor Co. The National company will handle tire accessories and used cars, and will also engage in general repair and garage business.

New Savage Tire Agencies—The Savage Tire Co. of California, manufacturer of Savage tires, has established representation in Seattle with the Tyre Shop, 607 East Pike Street, Seattle, Wash., of which H. B. Wilbur is manager. The firm will act as distributor in Seattle and the territory north to the Canadian boundary line. The Savage Tire Co. also has established a distributing agency for the State of Oregon at Portland.

New Gasoline Stations in Los Angeles—With the completion of ten gasoline service stations in Los Angeles, the Ventura Refining Co. is now in better position to supply the trade. The service stations conform in detail to the style of architecture found in the old California missions. Aside from the unique style of architecture, a striking feature is an absence of gaudy signs. Only a small gold-lettered sign giving the name of the company and a mission bell, the trademark of Ventura gasoline.

Recent N. Y. Leases—The Jandorf Automobile Co., New York City, has leased the fourth floor of 239-241 West Fifty-sixth Street, and also the entire building at 303-307 West Fifty-ninth Street. The Hayes-Diefenderfer Co. has leased the second floor at 239-241 West Fifty-sixth Street. The C. T. Silver Co. has leased the top floor of 3-7 West Sixty-first Street. This company has moved to its permanent home in the Silver Building, corner North Broadway and Manor House Square, Yonkers. The Globe Tire Co., formerly at 228 West Fifty-eighth Street, has moved to 1853 Broadway, where larger quarters have been attained. The Holbrook Body Co. has leased 28,000 sq. ft. in the block Forty-third to Forty-fourth Street, Eleventh and Twelfth Avenues. The Ford Steel Pneumatic Shock Absorber Co. has leased space in the Circle Building, Columbus Circle. The Akron Tire Co. has taken space in the Thoroughfare Building, 1777 Broadway. The third floor at 319-320 West Forty-eighth Street has been leased to the Maxwell Motor Sales Co.

A lease has been made by the Kent Motors Corp. for one-half of the fifth floor in the building at 1700 Broadway The Pullman Motor Car Co. has leased space at 1922 Broadway. The building at 233 West Fiftieth Street has been taken by the Northern Pacific Motor Co.

Denver Trade News—The Platt-Fawcett Motor Co., 1249 Broadway, Denver, Stearns, Paige and Mitchell distributor for Colorado and Wyoming, has dropped the Mitchell and is handling the other two exclusively.

The Maines-Hough Motor Co., 439 Broadway, Colorado and Wyoming distributor for the Chevrolet and Monroe, has added the Mitchell agency for the same territory.

Shannon G. Loes, formerly sales manager for the Jones Motor Car Co., Inc., Richmond, Va., Cadillac distributor, has taken the position of sales manager for the Charles F. Cole Corp., 35 East Colfax Avenue, Denver, Pathfinder distributor for Colorado and Wyoming.

W. R. Woods, formerly Hupmobile agent in the Cripple Creek, Col., district, has been made sales manager for the Hupp Motor Sales Co., 1260 Broadway, Denver, Colorado and Wyoming distributor for the Hupmobile and Locomobile. George De Witt, formerly district salesman for the Cadillac in Texas and Louisiana, and also formerly well known as a Buick racing driver, has been made assistant sales manager and given charge of the city sales for the new Hupmobile concern.

The Denver local agency for the National has been transferred from the A. T. Wilson Auto Co. to W. F. Bell, 1616 Broadway.

Tom Botterill, 1278 Broadway, Denver, Dodge, Pierce and Hudson distributor for Colorado, Wyoming and Utah, has left for Detroit and Buffalo to visit the three factories. He is accompanied by Frank Botterill, a brother and manager of his Salt Lake City branch, which is known as the Tom Botterill Automobile Co.

W. W. Beeson, Colorado and Wyoming distributor for the National, has opened permanent headquarters at 1616 Broadway, Denver.

The Victor Auto Co.'s garage, Victor, Col., has been established as official Hupmobile service station, to work in connection with the Woods Auto Co., Hupmobile agent for the Victor district.

W. F. Bell has secured the Colorado and Wyoming territory for the Monarch, and has established headquarters at 1616 Broadway.

Plans have been completed by the Northwest branch of the Metz Company for a three-story fire proof building on East Pike Street, Seattle. The building will be completed by March 1 at an estimated cost of $25,000.

Paterson Agency Moves—R. W. Vining, who has the New England distribution for the Paterson, has just moved into new quarters in a building at 1121 Commonwealth Avenue, Boston, Mass.

VOL. XXXIII. NEW YORK—THURSDAY, NOVEMBER 4, 1915—CHICAGO No. 19

The AUTOMOBILE

Vast Progress in Motor Design

Nearly All Engines of Recent Design Are Years Ahead of 1915 Models—Higher Pressures and Higher Speeds the Rule —Better Lubrication—Less Vibration— Greater Economy

By A. Ludlow Clayden

NEVER in the whole history of the automobile has the design of any part progressed so much in one year as has that of the American automobile engine during 1915. Owing to a variety of causes, change was forced upon the motor manufacturer and upon the automobile makers. The opportunity has been seized upon by engineers to let loose the pent up knowledge they had accumulated through the several years previous, so American engine design and construction has leaped forward in a year as far as Europe advanced in the previous three or four. From a position in the rear, in the engineering sense, the American motor has made a forced march to the van and stands alongside the best of foreign products.

Higher Speed

It is greatly to be regretted that the habit ever arose of estimating speed by revolutions per minute. The speed that counts in an engine is the speed of piston movement in feet per minute and it is easier to get high crankshaft speed than high piston speed. On a 3-in. stroke 3000 r.p.m. means just the same piston speed as does 1500 r.p.m. for a 6-in. stroke, so there is little sense in calling the former a high speed and the latter a slow speed engine.

Similarly, horsepower ought to be plotted against piston speed rather than against revolutions, and the quality of the engineering in a motor is better judged by a curve of brake-mean-effective-pressure plotted against piston speed, than it is by any ordinary power curve plotted to revolutions. Of course, both curves show the same forces and velocities in different forms of expression, but the ηp-piston speed curves are at a glance, indicative of the relative quality of two motors while the hp.-r.p.m. curves are not.

Still, however the plotting is done, the fact remains that piston speeds have risen enormously this year, and in conjunction gas speeds through valves and passages. Simultaneously, modern motors are expected to operate at slower speeds than formerly, so the total range of speed has been widened at both ends. This has made things distinctly difficult for carbureter makers, but they have risen to the occasion very well.

Demands of User Complex

The automobile engineer has this year been asked to give the following new features to his engine:

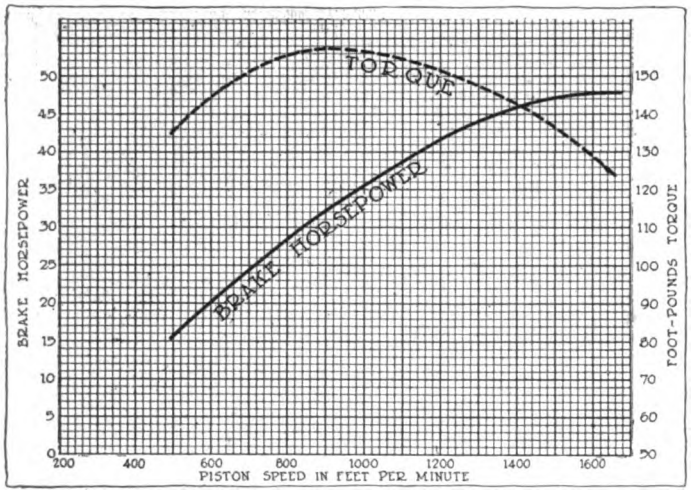
Higher maximum speed.
Lower minimum speed.
More power at all speeds.
Greater quietness.
Better gasoline economy.
Lighter weight.
Less vibration.
Better oil economy.
Smoother torque.
Cheaper construction.

These make up a fairly formidable array of problems.

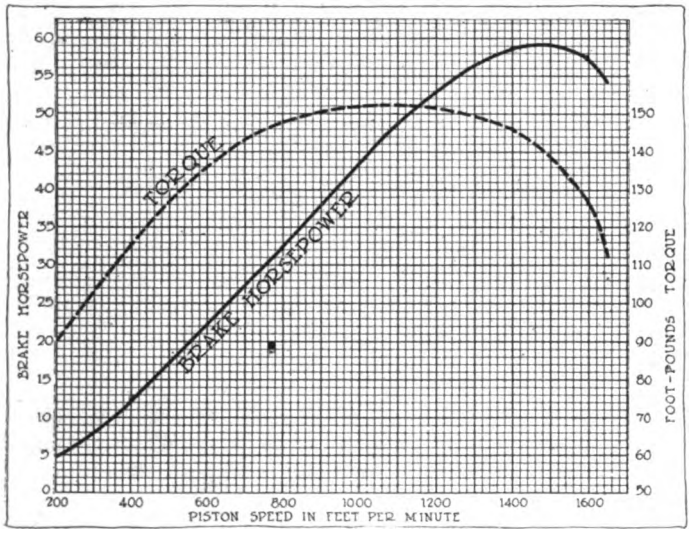
To get the nearest approach to satisfaction of all these demands there has been produced:

The eight.
The twelve.
The aluminum piston.
The aluminum cylinder.
Larger crankshafts.
Higher pressure lubrication.
Higher compression.
Larger valves.
More elaborate cams.
Simplified gas passages.
Greater rigidity.
Less machining.
New machine tools.

Much credit for the progress made belongs to [illegible] shop men, the factory superintendents and [illegible]



Power and torque curves for the Continental light six, 3½ by 5 in.



Power and torque curves for the Ferro eight, 3¼ by 4 in.

whose names never reach the automobile public. Without the able support and help of these men the automobile engineers would have been handicapped heavily, for the all important requirement of inexpensive manufacture would have been impossible to combine with better performance.

Overhead Valve Position Speculative

Before descending into detail on what has been done, there are a few trends which should be noticed. A conspicuous one is that toward the overhead valve and this is likely to persist. The old idea that an overhead valve is essentially noisy is exploded utterly, the present trouble in the main is to control the lubrication of rockers and parts above the cylinders without flooding the valves themselves.

Intimately bound up with the overhead valve is the detachable cylinder head that is returning to popularity, both for cheap motors and engines of the very highest class. Whatever the type of valve, the detachable head is a great advantage to the car owner, because it renders carbon removal and valve grinding far easier than with any one-piece L- or T-head motor. It is a manufacturing advantage with most designs, and there is now no difficulty in replacing a head so that the water and gas joints are tight. Probably less leakage occurs with the detachable cylinder head than normally is found around the valve plugs in the other type.

Given the detachable head and the necessity for valve cages disappears, and it is the cage that has been liable to give most trouble in overhead valve motors.

Cages are satisfactory if the volumetric efficiency is not very high, but as soon as pressures and temperatures rise there occurs trouble in cooling the valve cage seating and danger of cracking the cage. It is only on racing motors that valves with seats in a non-detachable cylinder head are permissible, because valve grinding under such conditions is almost a factory job, as was found by the Hispano-Suiza Co. with a model of car that cost them much trouble and distress two years ago.

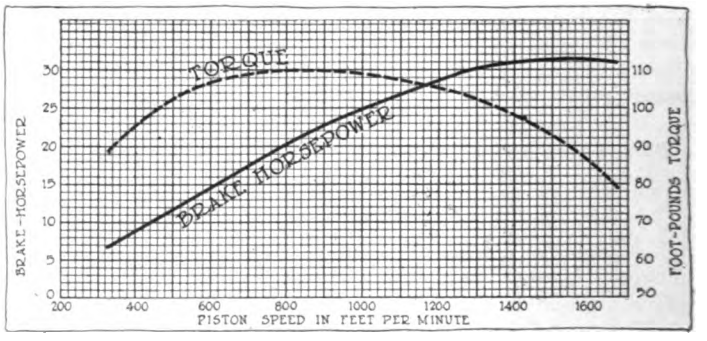
Overhead Camshaft Not Popular

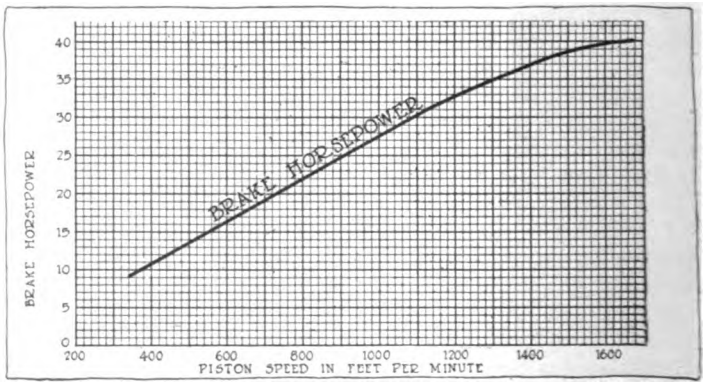
While it becomes universal for racing, the overhead camshaft is not too attractive for touring car engines, because a quiet drive is difficult of attainment and lubrication is rather complicated. With the camshaft in the usual place and long, light push rods, it is now easy to design an enclosed rocker mechanism which will be self-lubricating without a pump feed, and the final arrangement will be more accessible than any overhead camshaft job.

Of course the overhead shaft is comparatively new and development may easily show some scheme for simplification. The present situation is that the overhead valve presents no specially difficult problems, while the overhead camshaft still does. The self-lubricating bushing in which graphite is used as a part of the bearing surface has been applied successfully to the rockers of overhead valves and this needs little, if any, oil to keep it in good condition. Also there is the spherical end type of rocker like that used on the Brush engines, which contains its oil and uses all the lubricant without waste. The main reason for the overhead camshaft is to reduce to the minimum the reciprocating weight of the valve operating parts. For an engine to be used in a touring car the lightness obtainable by employment of an overhead camshaft is not *yet* necessary, wherefore it is more likely that overhead valve development will be mainly in connection with camshafts in the crankcase position.

Chain Drive Camshafts Slow

The chain-driven camshaft has not developed to the extent expected, and the reason is mainly that manufacturers have been loath to spend enough to insure good chain. Good chain is expensive to make and cannot be sold cheaply, and there are only a very few firms in the world who can make really

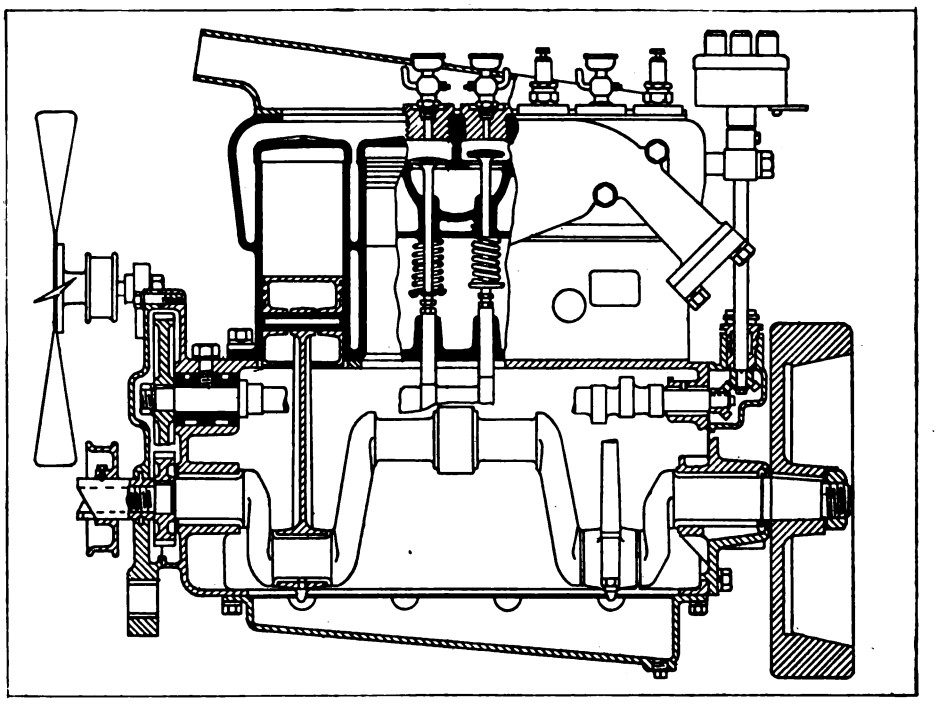




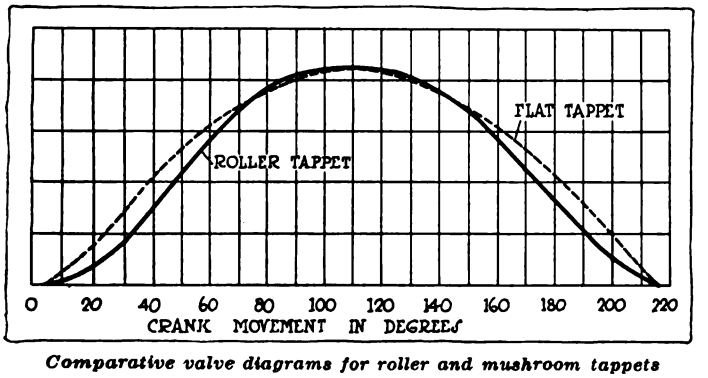
Power and torque curves for Northway four, 3½ by 5 in. and power curve for Rutenber eight size 3 by 5 in.

good chain. Also, the application of a chain drive needs expert knowledge and automobile designers have often used chain in a way that no chain maker would approve. In such cases failure is usually blamed on the chain, which is totally unjust.

On the other hand, those few people who have used chain intelligently are extremely pleased with the result, and especially comment should be made on the success of the Packard-Morse automatic adjustment. It will be remembered that the Packard twin six has a triangular chain drive and that the sprocket which drives the pump and the generator contains within it an Oldham coupling which is in permanent operation. This coupling has taper tongues and this prevents the development of slack, while spring pressure takes up what little wear may occur. The device is simple, and has proved thoroughly effective, it is an American idea used with American chain and the results are better than the average attained with imported chain which was the most reliable sort in the first attempts made by motor builders at chain layout.



The Perkins four; a well-known small engine of great simplicity and featured by the small number of parts. Several sizes are made of correspondingly clean design



Comparative valve diagrams for roller and mushroom tappets

TABLE I

Port Beneath Valve Diam.	Valve Area	Equivalent Valve Lift For— Flat	30°	45°
1	0.785	0.25	0.26	0.35
1 1/16	0.886	0.26	0.27	0.37

1 7/16	1.623	0.35	0.37	0.51
1 ½	1.767	0.37	0.39	0.53
1 9/16	1.917	0.39	0.40	0.55
1 ⅝	2.074	0.40	0.42	0.57
1 11/16	2.236	0.42	0.44	0.59
1 ¾	2.405	0.44	0.45	0.62
1 13/16	2.580	0.45	0.47	0.64
1 ⅞	2.761	0.47	0.48	0.66
1 15/16	2.948	0.48	0.50	0.68
2	3.142	0.50	0.52	0.70
2 1/16	3.338	0.51	0.53	0.73
2 ⅛	3.546	0.53	0.55	0.75
2 3/16	3.758	0.55	0.56	0.77
2 ¼	3.976	0.56	0.58	0.79
2 5/16	4.200	0.58	0.60	0.81
2 ⅜	4.430	0.59	0.61	0.84
2 7/16	4.707	0.61	0.63	0.87
2 ½	4.909	0.62	0.65	0.88

Where gears are used for camshaft driving it is often found that a chain is used for the generator shaft. That is an anomaly which cannot endure and it is reasonable to expect that the complete adoption of chain driving will follow.

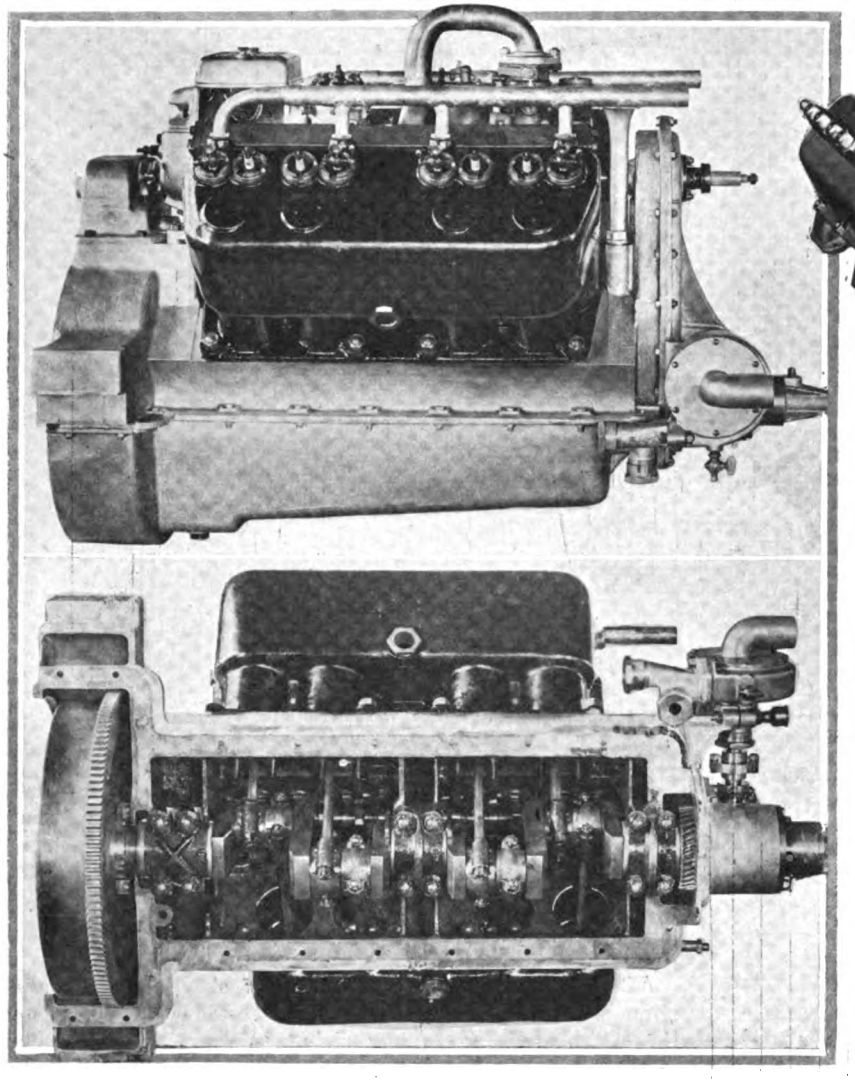
Aluminum Pistons Arrive

After years of experiment, years of skepticism, the aluminum alloy piston has been accepted and bids fair to become the standard. The rapidly rising price of aluminum has retarded this development, but despite the high price aluminum pistons are now fitted to motors on quite cheap automobiles. The aluminum piston, weight for weight and strength for strength, is the cheapest type. The light weight is necessary because of high piston speeds and it is cheaper to obtain it by using aluminum than by elaborately careful machining of iron or steel. There is less machining on an aluminum piston than on any other type, and it is easier machining too. Between die-cast and sand-cast pistons and pistons cast by a combined process part die and part sand, much argument remains which time alone will settle. It must be remembered, however, that die-casting is still in its infancy, while sand casting is not and the tendency is towards die-casting. It may prove to be but a temporary trend, but that it should so do seems improbable.

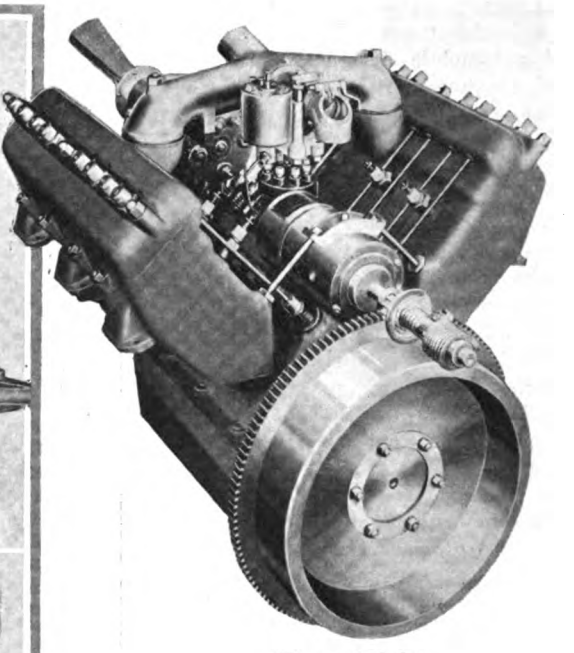
Aluminum Cylinders on Trial

In the race for lightness, the aluminum motor makes its debut as a standard product on one 1916 car alone. Naturally this is a high-priced car, for aluminum cylinders are out of reach of the cheap car maker with the metal at its present price. During 1915 something like fifty cars have been in use with aluminum cylinders, and none have given trouble on this account. Each automobile was some 80 to 120 lb. lighter on this account and so great a saving is well worth a small price increase. Development along this line depends entirely on the price of aluminum; should this fall the aluminum motor will become common very rapidly, but if it rises the day of aluminum cylinders will be postponed. At present that is all there is to be said.

A gear ratio of 4.5 to 1 on high gear means a crankshaft speed of 2000 r.p.m. at 50 m.p.h. approximately. Again

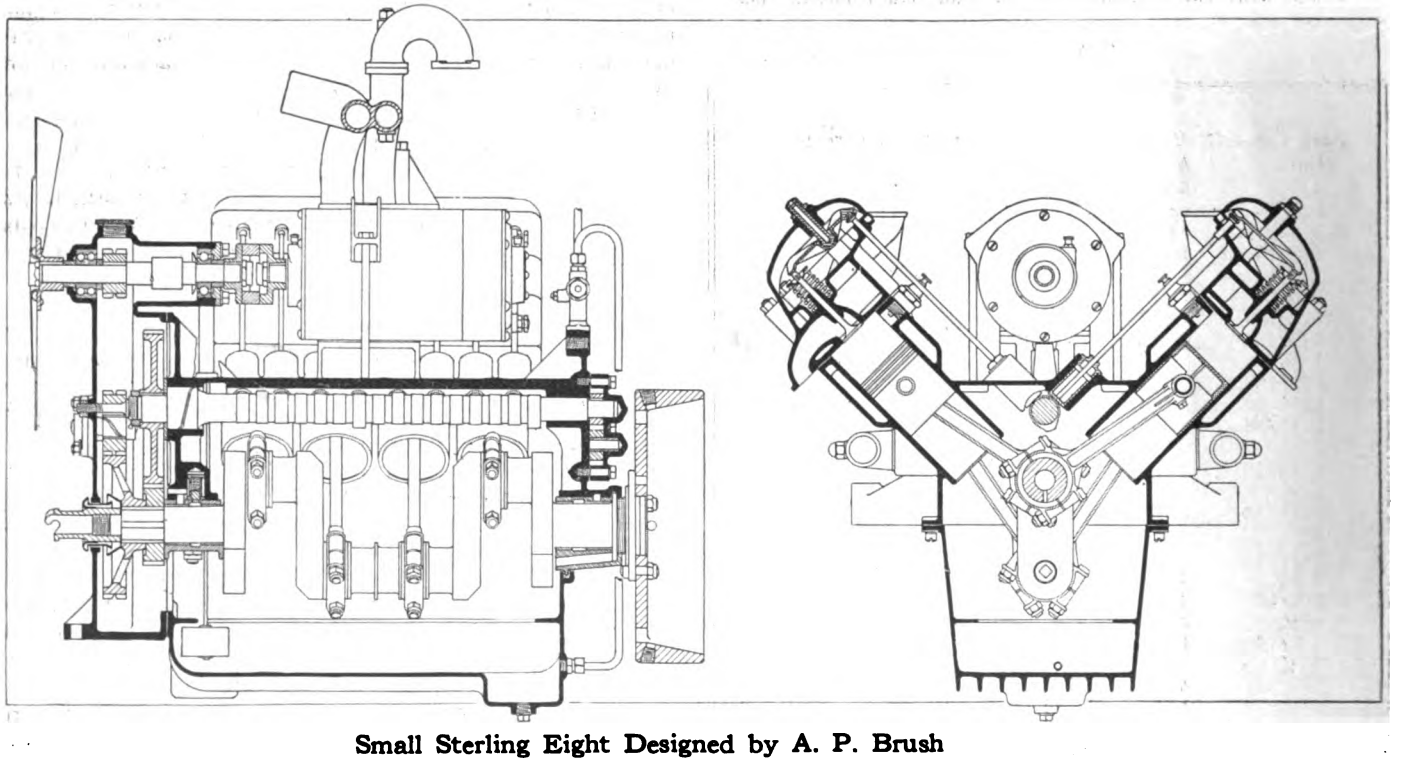


Herschell-Spillman Eight

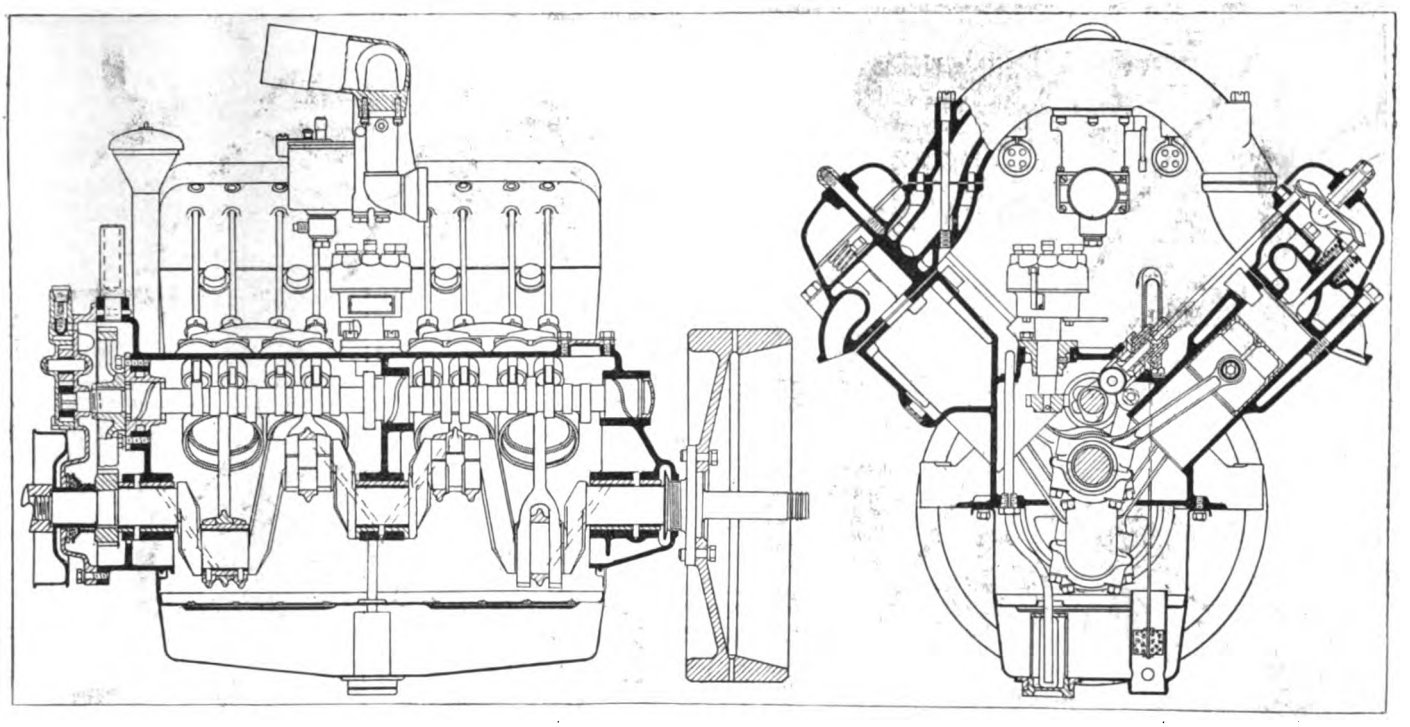


Ferro Eight

SIX DIFFERENT EXAMPLES OF V-TYPE EIGHT CYLINDER MOTORS ILLUSTRATING ALL PRINCIPLES OF DESIGN

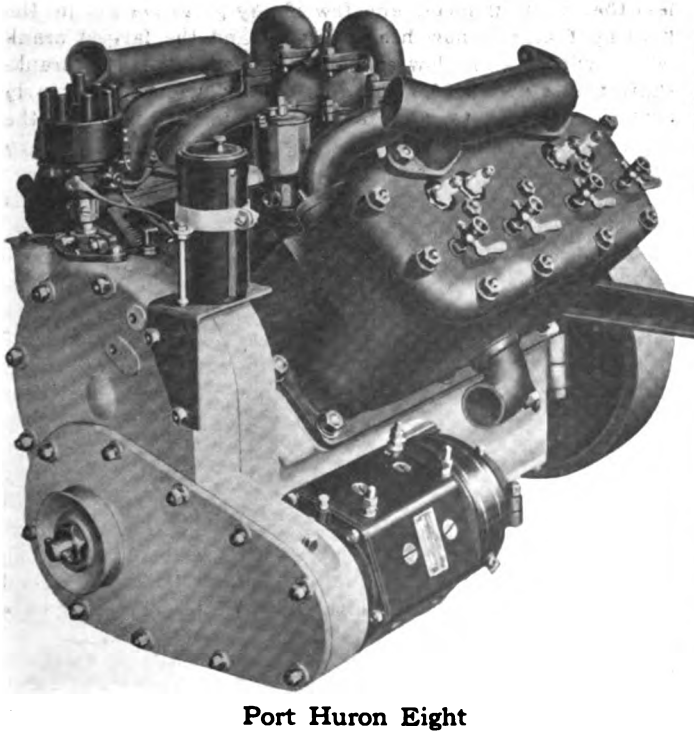


Small Sterling Eight Designed by A. P. Brush

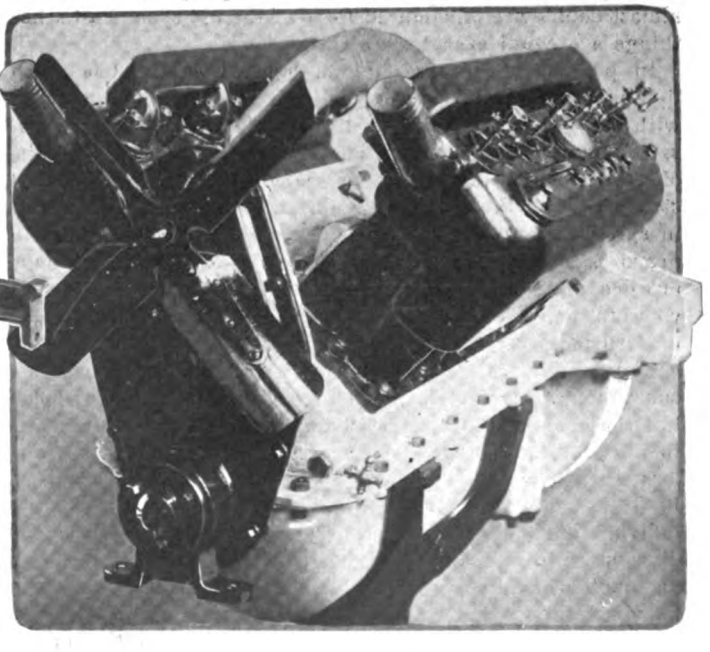


A contrast in eights is provided by a Herschell-Spillman on the left of page 824 seen from the side and from beneath, and the Ferro beside it. The former is an L head motor and has the side by side connecting rod arrangement, while the latter is provided with the most up-to-date idea in overhead valves and use the forked connecting rod system. The great rigidity of the bearing support in the Herschell-Spillman motor is observable. The bearings in this motor are finished by an unique burnishing process. Connecting-rod bearings can be taken up just as for any other type of motor. At the bottom left of this page is the Port Huron eight, which is distinctive by having the camshaft very high up. The valves are inclined at an angle of 135 degrees, which enables one cam to be used for each opposing pair of valves with straight push rods and no rockers. Detachable cylinder heads make the valve heads accessible and the wide angle brings the tappets into a position where they can be reached without as much trouble as usual in L head eights. Beside it is the Buda eight, a robust motor with all the characteristics of high quality workmanship that have given the Buda fours and sixes their reputation for long, trouble-free service.

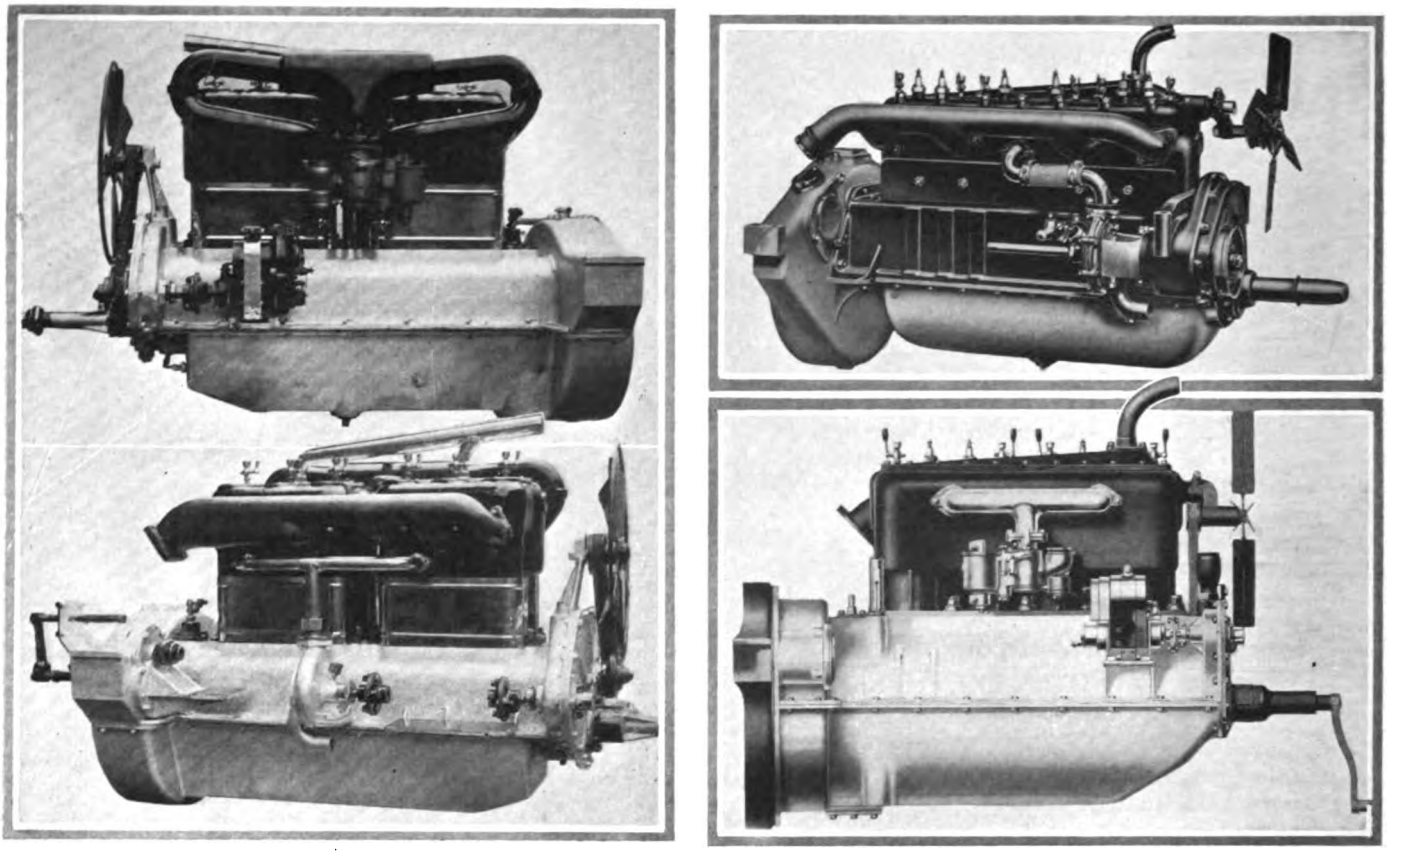
The drawings show two examples of the eights designed by A. P. Brush. That on this page is the Ferro and that on the page opposite is the Sterling. They have many points of similarity, of which the principal one is the overhead valves, the special type of rocker operation, and the casting of the two blocks of cylinders in one piece with the upper half of the crankcase. As can be seen in the cross sections, the rockers seat on ball shaped bolt heads instead of on the ordinary pin joint, and this facilitates adjustment because the bolt can be screwed down a little from outside the motor, so lowering the whole rocker and taking up any slack. Points of difference are that the Ferro, which is the larger, uses three crankshaft bearings and forked connecting rods, while the Sterling has the other kind of rod and only two crankshaft bearings



Port Huron Eight



The Buda Eight



These are three typical and different motors. On the left two views of the Herschell-Spillman six, a large and powerful T head design. The intake is a Herschell-Spillman specialty. Excellent accessibility is a conspicuous feature as can be seen by the ample space round every part. Top right is the popular Continental light six, a new motor this year. It has a one-piece cylinder block and crankcase upper half and is 3½ by 5. The oil pump is a plunger, driven off the camshaft and so very accessible, while valve accessibility is assured by the detachable cylinder head. Right lower, is quite a different sort again, being a heavy duty Wisconsin four. This is the only motor in the group with an L head cylinder and it may be seen that the carbureter and magneto are very easy of access

approximately, this gives a piston speed of 1700 ft. per minute at 50 m.p.h. or 70 per cent above the speed on which the formula horsepower is based, if we assume an engine with the extremely popular stroke of 5 in. This increases the amount of any unbalanced force, or the pressure on the bearings due to inertia of the reciprocating masses as much as 89 per cent. In other words, the high-speed engine has almost double the unbalanced force of the old type if all other things are equal except gear ratio.

In practice, of course, the high-speed engine has much lighter parts, and therefore is able to run at high speed with no greater vibratory stresses than the larger slow-speed motor, but the public have not been satisfied with the old type; so it has been necessary to reduce unbalanced stresses below the old level simultaneously with an increase in speed. Increasing the speed increases vibratory stress in proportion to the square of the speed and dimensions have not decreased in proportion to the square root of anything, wherefore much higher engineering quality is necessary in modern motors.

The weight of reciprocating masses has been reduced enormously, size for size, and pressure on bearings reduced likewise, so that the balanced and unbalanced stresses due to the reciprocating masses in a 1916 engine may easily be less than in a 1915 engine of the same piston displacement. Multiple cylinders reduce the unbalanced forces by reducing individual piston weights, and higher speed sixes have allowed dimensions to be cut and weight reduced in proportion. With any motor having more than four cylinders it has been the balanced forces that have proved most troublesome.

An automobile engine is balanced by virtue of the ability of the crankshaft to hold adjacent pistons so truly in relative positions that the unbalanced forces due to the pistons individually cancel out. As the stresses increase in proportion to the square of the speed the strength of the crankshaft has been forced up likewise, and thus we see cranks on motors of 3 in. bore now often of well over 2 in. diameter. This vibration question has destroyed any idea that may have existed as to proportion between bore, stroke and crank diameter. In practice few modern motors have crankshafts less than 2 in. diameter and few if any go above 2½ in. the limiting factor is now bearing speed and the largest crank which will keep this low enough is employed. A 2-in. crankshaft turning at 3000 r.p.m. has a bearing speed of nearly 1600 ft. per minute, and 1800 ft. per minute is above the safety limit for ordinary bearing materials and ordinary lubrication.

Though it has so far appeared on one car only, the use of the Lanchester damper for eliminating the effect of torsional vibration from crankshafts marks a stage in development, because it belongs to a class of fitting hitherto considered "uncommercial." There are now so many motors which run without perceptible vibration up to road speeds of 40 m.p.h. or over that the automobile user is going to get extremely critical. For this reason it is safe to predict that the moderately large number of coarse running, roughly made engines still manufactured are entering their last season.

Cheaper cars and better equipped cars has been the cry for many years and the leaders of industry have stood still on engineering quality. Now, engineering quality is improving rapidly in the more costly cars and the cheaper field is following fast. Nineteen hundred and sixteen has marked the beginning of a change which will take three or four years to consummate.

Valves Are Larger

In Europe two years ago, it was obvious that the stock motor makers had picked upon a valve diameter equal to half

the cylinder bore as the practical maximum, and large valves with a small lift were used generally because this combination gave the greatest opening with the least noise. To-day the best American engines have valves of just about this same proportion and it is customary to find the lift is such that the full port area is available at maximum opening. Table 1 shows the lift of valves with flat and angular seats to give maximum opening for 1 in. to 2½ in. ports.

Now, maximum lift and large diameter is not all that requires consideration for the important thing from the viewpoint of volumetric efficiency is the average valve opening during the cycle. The constant acceleration cam profile is usually considered the ideal, but it is worked to very seldom, because to form a cam of this character calls for very delicate machining and the use of grinding wheels which have a very short life. The flat sided cam gives commercially good results on moderately priced jobs, but the fact that the more elaborate profile is really much better offers a great opportunity to the ingenuity of the machine tool trade. There is a huge field for a robust cam-grinding tool which will produce small, constant acceleration cams at reasonable cost.

Quietness of valve operation has been shown to be affected greatly by the weight of the tappets, and a light tappet enables a lighter valve spring to be used. Everything which will reduce the inertia of the valve, tappet and valve spring is desirable. It is the search for quietness that has caused the roller ended tappet to gain in favor, for a slightly better diagram is obtainable with the mushroom type, when a flat side cam is used. Curves on page 823 show characteristic diagrams for cams of different forms with differing tappets.

It must be remembered, however, that the diagram obtained at high speed may differ greatly from the theoretical, as the tappet has a tendency to "float" and actually does so as a rule at speeds exceeding 1500 r.p.m. In this connection it is claimed that there is advantage in using two light springs instead of a single heavy one, the theory being that all springs have a certain amount of hysterisis and that this is lower in the case of two small concentric springs than in one large spring of heavier section. This is by the way, however, as there is no stock motor yet in which two springs are used on each valve.

Lubrication a Difficulty

With the coming of higher piston speeds lubrication has become troublesome. Particularly in engines with many small cylinders, where the total piston periphery is large in proportion to the piston displacement, there has been a tendency for water to deposit in the crankcase and this has given great distress to several manufacturers. The reason is that the loose pistons deemed necessary for high speeds have allowed products of combustion to pass freely at low speeds, and the water from these products has condensed. Hence the efforts of V motor makers have been rather to insure the presence of plenty of oil in the cylinders than otherwise. The trouble is new this year, and is serious, because the water has a terribly destructive effect.

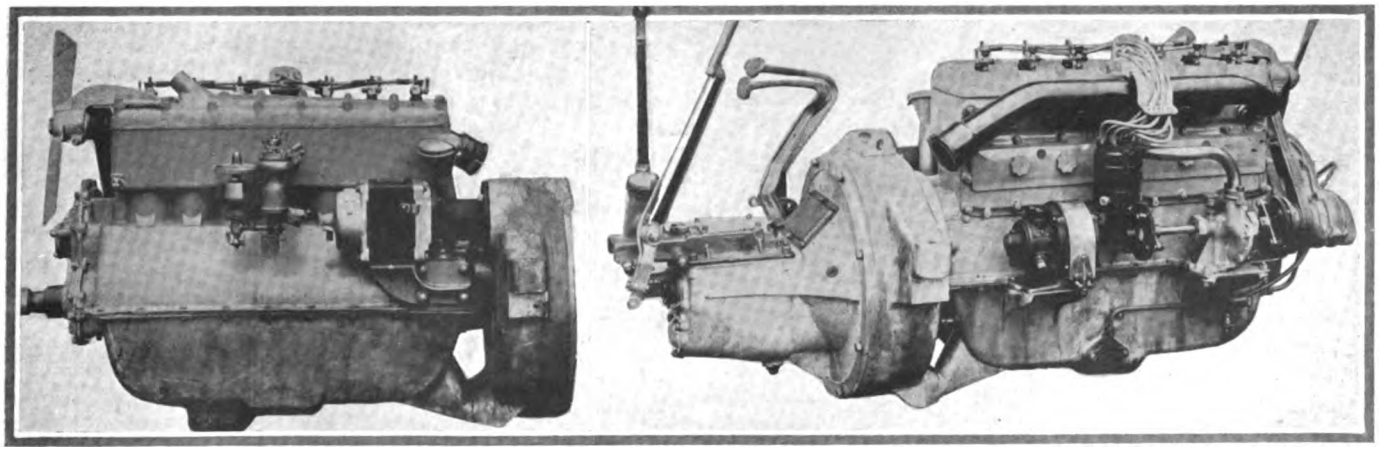
To overcome it, for it has been overcome, pistons have been tightened a little and bottom rings or V shaped "lifting" grooves have been put in the piston skirt. None the less the user of a new car may find it worth while to change the oil a little more often than he had to do with older cars.

The most striking development of lubrication has been the coming of the pressure system. This has gained steadily for years, but has been regarded as complicated for some mysterious reason. A splash system needs a pump to maintain constant level, crankshaft bearings will wear longer in proportion to the pressure of the oil entering them, to join the pump to the bearings by direct pipes is *simpler* and just as cheap as to make gutters and pockets to catch splashed oil. Hence to call pressure feed to the main bearings complicated is absurd.

Then for the crankpins, what could be simpler than a drilled crankshaft? It costs more than the dip troughs, but a hole through a shaft is less complicated than a system of troughs and feed pipes and guides and splashers. Say that the pressure system is more expensive, and the case is unarguable, but the extra cost is not great and the extra life of bearings, in a high-speed engine, is very great. Any engine that has a good bearing life with splash oiling will have a longer life with pressure oil. This being realized by the engineering leaders of design, we see many more motors appearing with the best system.

A drawback to high-pressure oil which caused much trouble in European development was that there exudes from the ends of the crankshaft bearings a whirl of oil spray which has a tendency to soak the cylinders. Fortunately for the American engineers, the aluminum alloy piston can be made of greater length than the European practice without increased weight and this, together with improved means for scraping the walls, has enabled oil pressures up to 50 lb. per square inch to be used without the production of smoke.

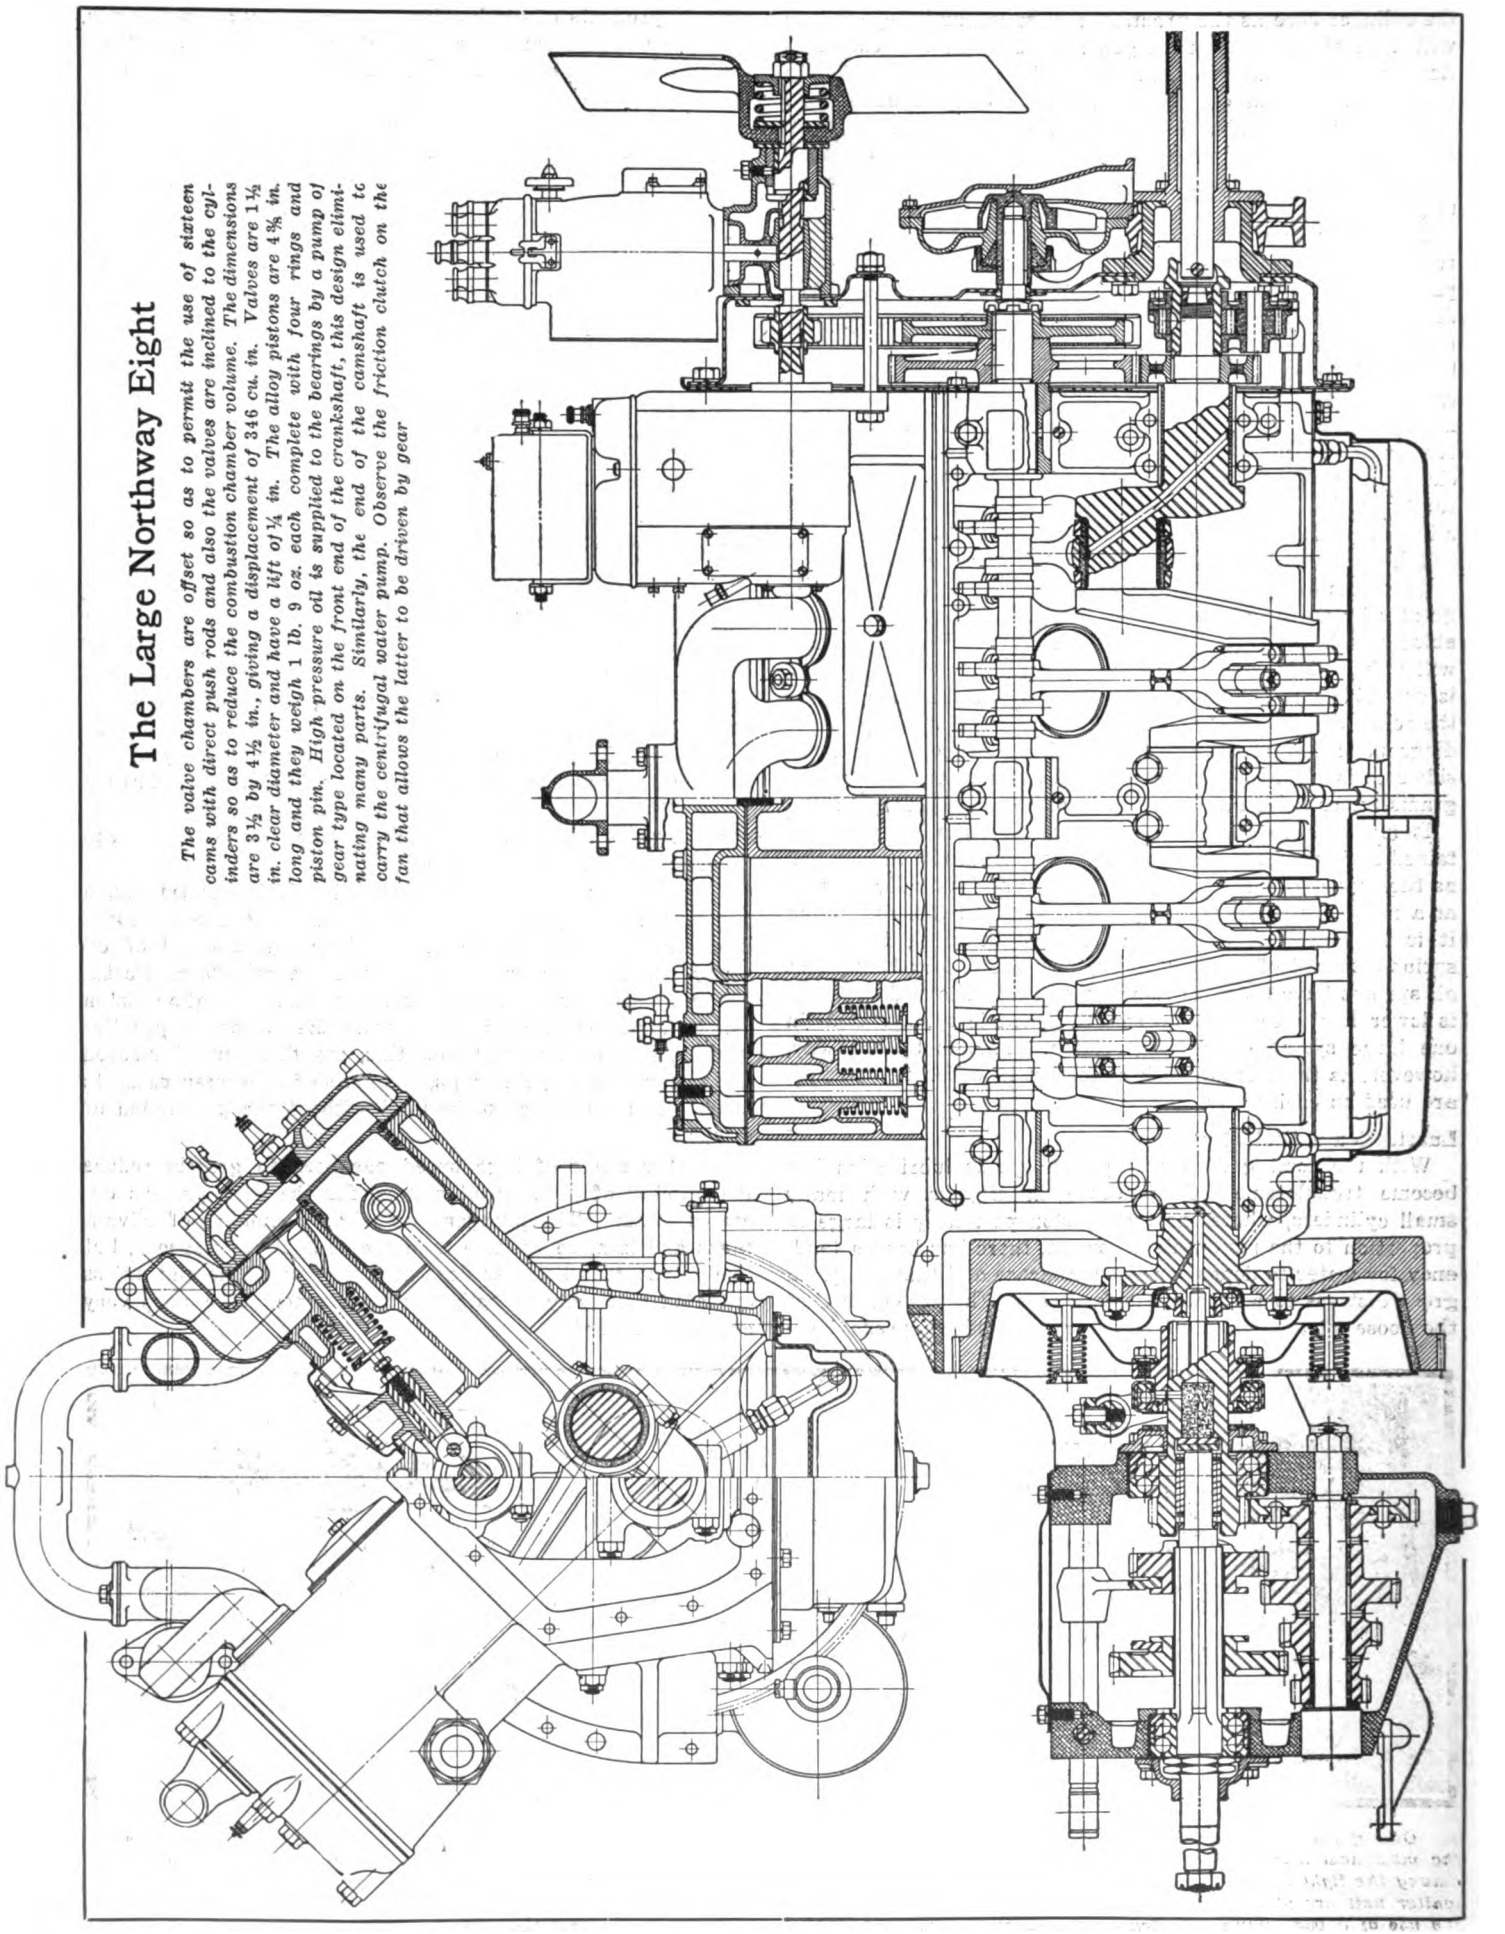
Another effect of high speed has been to greatly reduce the number of plunger oil pumps, for the gear pattern operates better. The plunger pump has a number of advantages and is more positive than the gear at slow speeds, but like valves, it is liable to float at high revolutions and unless operated positively in both directions when it becomes very expensive indeed.

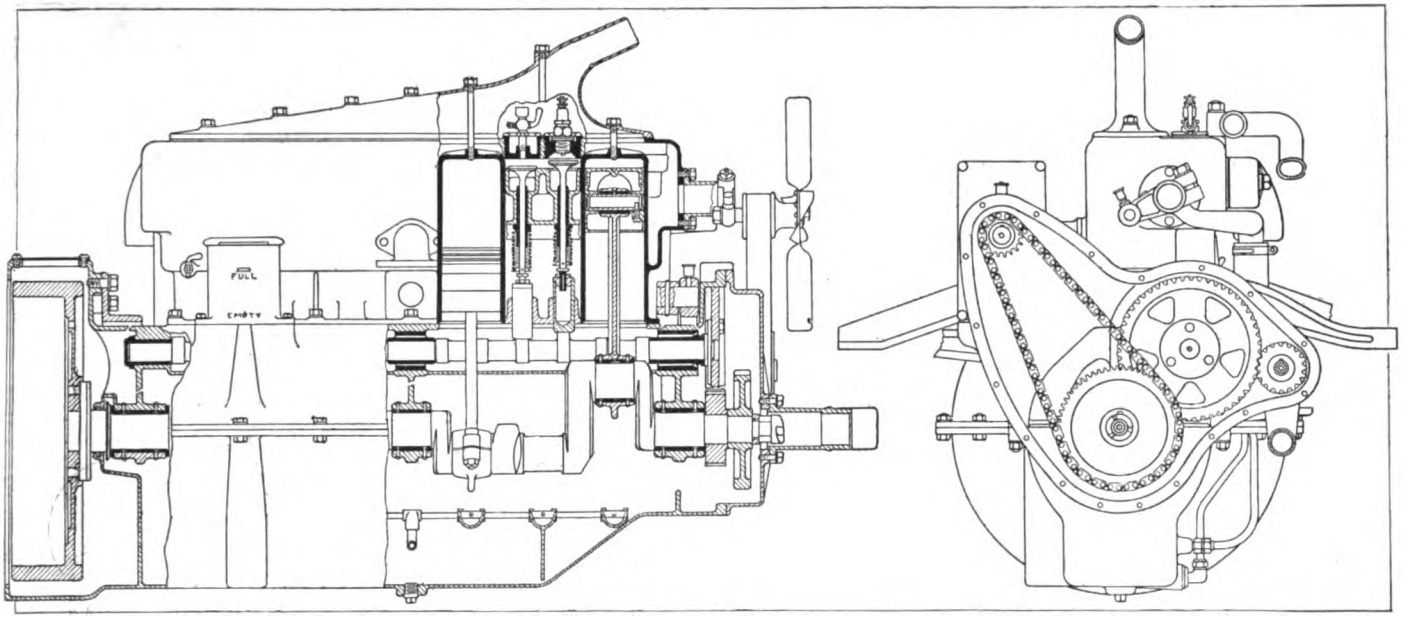


One of the most popular of the light sixes, and one of the most successful, the Rutenber 3 by 5-in. motor. This engine is one of the most neat and clean examples of the one-piece cylinder block and crankcase variety, and has the extra credit of being a pioneer among the light sixes of the year. All the intake manifolding is done within the casting, and the water pump with the generator and igniter unit are placed low enough to render tappet adjustment easy without removing more than the cover plate. A peculiarity is the use of a vane pump situated on the extreme front end of the cam-shaft for oil circulation, this also being very accessible

The Large Northway Eight

The valve chambers are offset so as to permit the use of sixteen cams with direct push rods and also the valves are inclined to the cylinders so as to reduce the combustion chamber volume. The dimensions are 3½ by 4½ in., giving a displacement of 346 cu. in. Valves are 1½ in. clear diameter and have a lift of ¼ in. The alloy pistons are 4⅝ in. long and they weigh 1 lb. 9 oz. each complete with four rings and piston pin. High pressure oil is supplied to the bearings by a pump of gear type located on the front end of the crankshaft, this design eliminating many parts. Similarly, the end of the camshaft is used to carry the centrifugal water pump. Observe the friction clutch on the fan that allows the latter to be driven by gear





A typical example of modern high-efficiency six-cylinder design is the Model motor made by the Pittsburgh Model Engine Co. The dimensions are 3 by 5 in., giving a piston displacement of 212 cu. in. The pistons are light iron castings and the crankshaft 1¾ in. diameter with three bearings. It will be noticed that the piston pin is fixed to the piston, a practice that is gaining favor. The valves are 1⅝ in. diameter with ¼ in. lift and the tappets are of light, hollow section with flat heads. In the front end gears are used for the camshaft drive and an adjustable chain for the generator drive

It is good to see that a few pioneers are taking up the matter of controlled oil supply and varying the pressure to the speed, or to the effort of the motor. This is absolutely rational as it saves oil and maintains the oil pressure in proportion to bearing load.

Stock Motor Lubrication

In stock motors, such as are most commonly used in cars built on the assembly system, the lubrication is almost universally by dip troughs in combination with separate leads to the main crankshaft bearings. A few motors have drilled crankshafts, but they are rare and not used on many cars. At one time a very popular stock motor system was to feed the dip troughs from an oil tank by an automatic "vacuum" air entering through a hole in the bottom of the tank when the level in the crankcase fell far enough and allowing a few drops of oil to escape. This was a fairly good system and did away with the pump, but it is not so accurate as pump filling for the troughs and is seldom used to-day.

With very few exceptions, where plunger pumps are employed, they are driven from an extra cam on the camshaft, the plunger being lifted by the cam and depressed on the suction stroke by a spring. Where there is a gear pump it is most often located in the crankcase and driven by a special vertical shaft off the camshaft. Of course the plunger is cheaper and it is just as good for speeds up to 1800 r.p.m. or a little over. It also has the advantage that it is easily accessible for cleaning.

In all motors almost, whether stock or special, there is room for improvement in the means provided for removing the filtering screen, but it is noteworthy that the 1916 stock motors are generally better provided with screening gauzes. Higher crankshaft speeds call for more perfect oil, as well as for better distribution of that oil.

Lubrication of Eights

When the Cadillac eight made its first appearance on the drafting board it was already the intention to make it a high-efficiency motor, to use high-working pressures and high-bearing pressures. Thus it was designed with a full pressure lubrication system as had been common on high-class fours and sixes abroad.

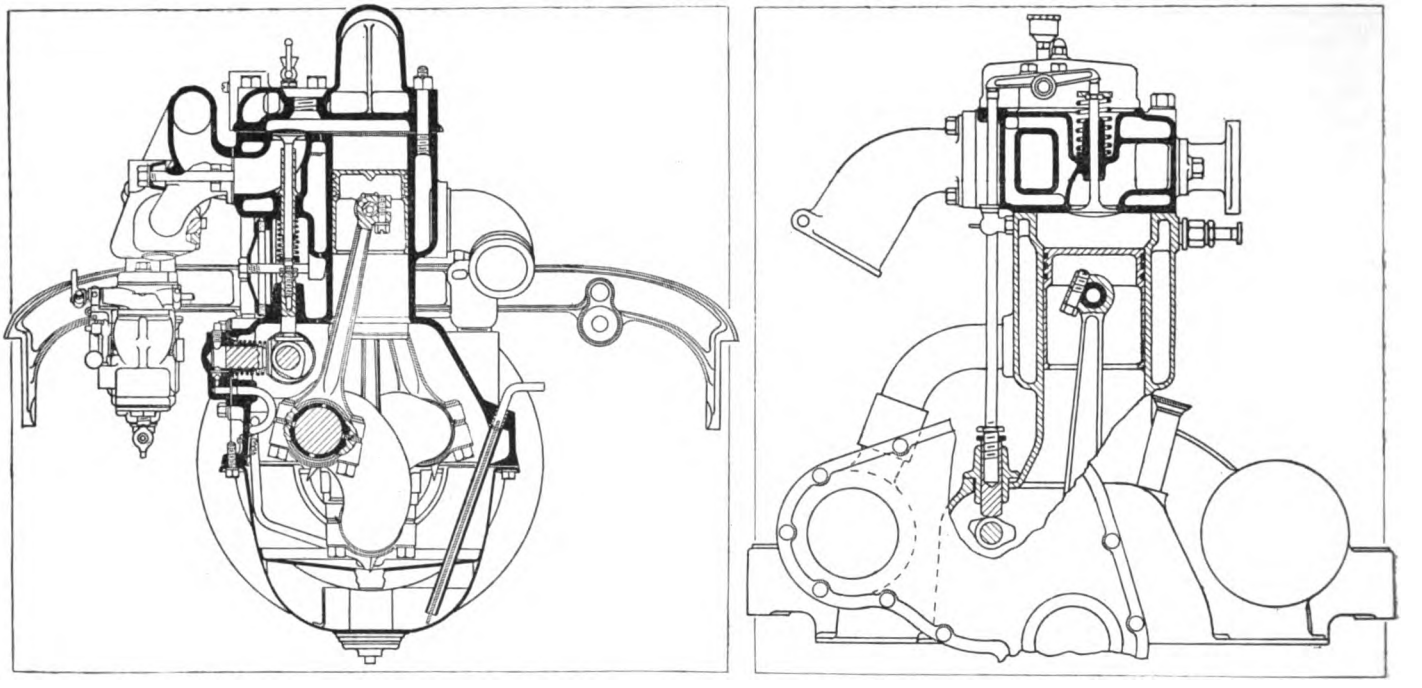
As the other eights appeared the desire to make them highly efficient as well as novel, persisted, so other designers and engineers turned to the pressure system, naturally. There then arose an impression that the eight *had* to have a pressure oiling system, for some mysterious reason, though this is not necessarily true. The fact is that to drill the simple four-cylinder crankshaft for internal oiling is much less expensive than to perform the same operation for a six, so the better system could be used without extravagance. Also the lower end bearings of the connecting-rods of the various patterns were all experimental to some extent, and the manufacturers felt safer with oiling that could not fail. Experience suggests that, if the maximum speed is not too high, trough oiling is quite practical for eights or even twelves. There has been remarkably little trouble with V-motors due to one set of cylinders getting more oil than the opposite set, as was anticipated at first, and it is quite possible that the absence of dip troughs has helped in this respect.

Effect of Eight on Other Types

This year has seen almost every engineer more interested in the V-motor than in anything else, so we often find that a big motor manufacturer has made his eight the principal new model, embodying most improvements, and has left the remainder of his product fairly well alone. The high pressures of the new eights have not caused trouble, the lubrication systems have worked out well and so on; wherefore it is to be expected that next year will show us various high-pressure, high-efficiency sixes and fours in which the experience gained with the eight will show up.

The tendency in this direction is shown by the various light sixes, which are designed to run up to speeds of 2000 to 2500 r.p.m. and are proving not only lighter, but actually more powerful than the older, larger motors. The light six stock motor is now to be found in the range of almost every manufacturer. Usually it is also an inexpensive engine, so in making it a great many desirable things have been combined.

Fours are so often made solely for cheapness that the efficiency enthusiasm has not yet put its mark upon stock motors of this number of cylinders. Here and there new designs have valves made larger, bearings bigger and everything stiffer, to permit increased revolutions, but the movement which is well advanced in the eights and is started and on



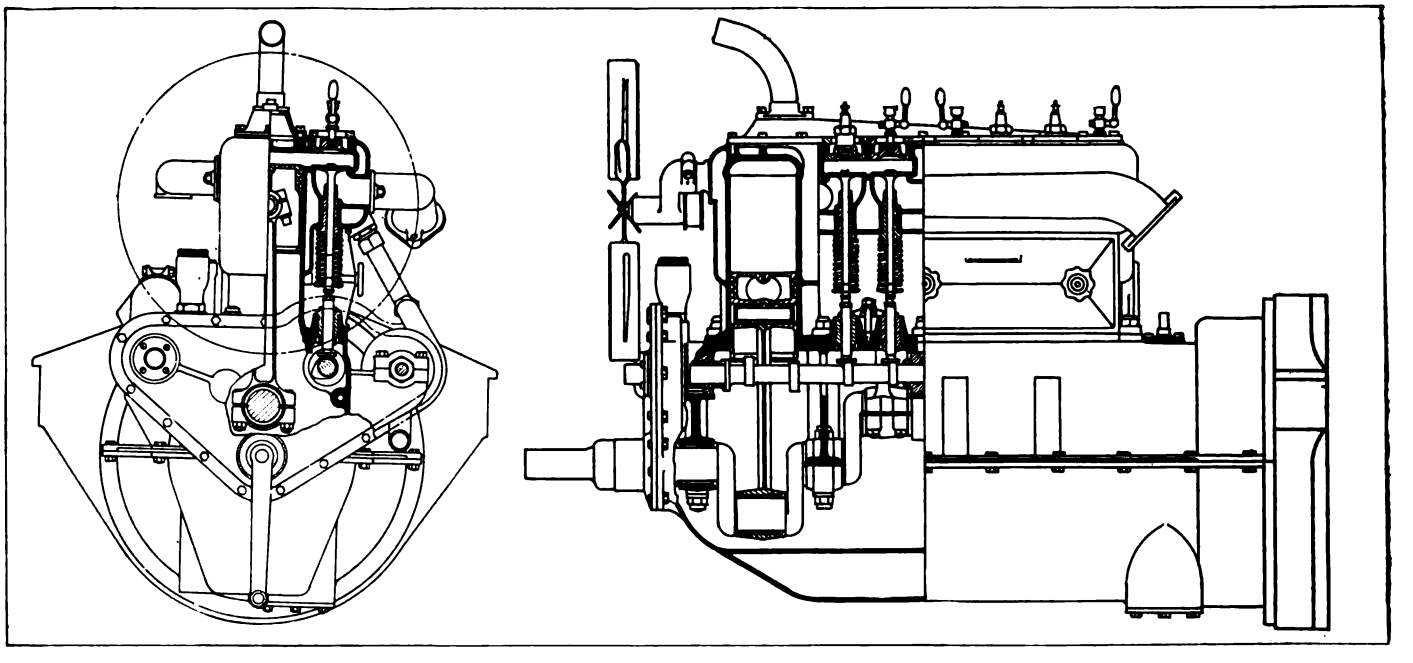
Left—One of the smallest and most widely used sixes is the Continental power plant of the little Saxon car. Note that the oil pump is operated off one of the exhaust cams and that there is a detachable cylinder head. Large waterways and free gas passages are also characteristics. Right—Section through the cylinder head and valve gear of a Falls motor cut through one of the exhaust valves. This section is instructive because it shows the way the intake manifold is carried through the water jacket on the head block, this being the inner rectangular black section just to the left of the valve

its way with the sixes is only to be observed in the stock fours by very close observation.

Water-Cooling Innovations

For circulating cooling water the centrifugal pump still is king. Thermo-syphon cooling gains slowly, but it does seem to be specially applicable to V-engines, because the low altitude of the latter allows a good head of water in the radiator and a good head is the life and soul of a successful syphon system of circulation. The thermostat, for controlling the flow of water in the circuit, has been perfectly satisfactory, but so also have systems without a thermostat. Probably the most correct view would be to say that the thermostat is a refinement which aids carburetion, especially in cold weather, but is an item of cost the moderate-priced car can afford to do without.

The most striking thing about water systems is not to be observed from outside a motor and seldom to be appreciated from sectional drawings, as it is the increased amount of water space allowed around the valve ports and pockets. In raising the efficiency of an engine the valves soon suffer if they are not well cooled, and also, which is more important to the average owner, if the valves are overheated and their accuracy of closing injured, slow running becomes uncertain.



Though primarily a heavy duty motor this example of Wisconsin manufacture is typical in outline. The four crankshaft bearings are a peculiarity which is favored by the Wisconsin engineers and give an exceptionally firm support for a four-cylinder crankshaft. The crankcase is all aluminum and lubrication is by pressure. Notice the very large water spaces behind the valve pockets, between the valves and the cylinders, also the light mushroom headed tappets. Slender valves are also a striking characteristic of this engine

It has been remarked that carbureter makers are being called upon to supply instruments which will give gas at very low speeds, and to do this a steady suction is imperative. If the valves are not functioning perfectly the suction will vary and the carburetion be upset. Hence, it is rendered doubly important that the valves should be in the best possible condition all the time.

Materials of Construction

The materials used for engine parts have undergone some change but not a great deal. The rising price of aluminum has rather encouraged the use of iron for the upper half of the crankcase, as instanced by several of the light sixes, and the popularity of the detachable head has helped this system of construction because it simplifies the foundry work. Casting an L-head motor with crankcase and cylinders in one with a fixed head is difficult because the cores become rather complex, but with the loose head the casting is easier than for an L-head cylinder block without the crankcase portion.

Probably, when the price of aluminum falls again, it will find the readiest application to cylinder casting by straight replacement of the all-iron designs, as the casting advantage is more than ever valuable with the lighter metal.

Steel as used for crankshafts is usually of about the same strength and character as that employed last year, as the upward trend in size of shaft enables more than enough strength to be obtained without the use of very high tensile material.

For valves tungsten steel would have been the rule, had the supply of the tungsten ore not been almost cut off by the war. Cast-iron heads welded to steel stems are still fairly popular, but are giving way slowly before the improved valve steels which mostly have tungsten as an element. The valve steel which gives best service in a high duty motor has some resemblance to the high speed steels that are most durable for cutting tools on high-speed machines.

Piston Valve Motor Provides Compressed Air

A NEW engine which has several features of interest including a device for air braking has been recently patented by E. U. Stewart of Long Beach, Cal. The motor is shown in section below. The primary object of the motor is to eliminate the poppet valve and to secure more even compression at all times by using piston valves instead. It is also hoped by the use of the piston valve to increase the efficiency of the motor without the addition of weight.

One of the purposes of the piston valves which are clearly shown in the illustration is that in making their working strokes they will pump air on the descending stroke and on the ascending stroke they will force the air into a storage tank attached to the motor. The general purpose of this air is to be used for air brakes, it being one of the inventor's ideas that it would not be necessary to use the foot or hand brake on long descents.

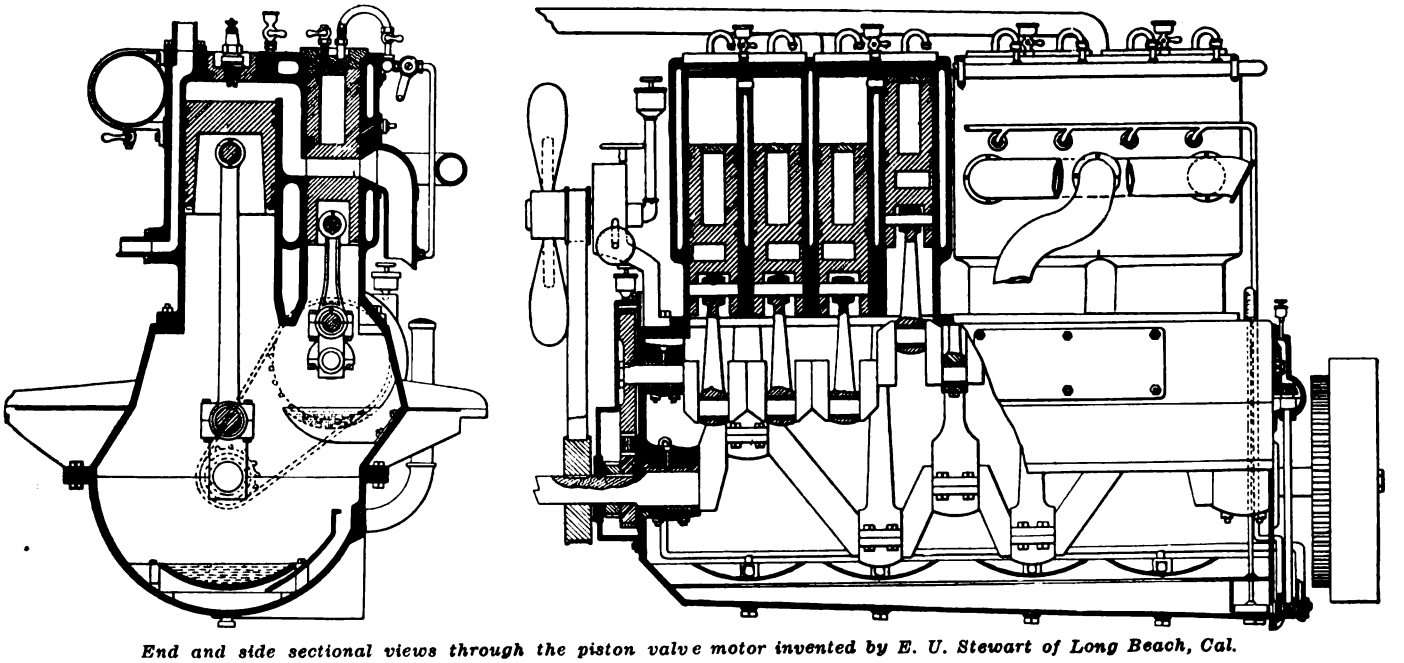
The air is also used for starting the motor, inflating tires, cleaning and dusting the car, raising an air jack, producing air for the carbureter and any other purposes for which compressed air in a clean, pure condition may be employed. The over-production of air passes through the exhaust to keep it clean.

In general, the motor is a four-cycle design which other than the valve mechanism does not vary materially from common practice, the oiling system is splash and force feed with rocking oil pockets. As may be noted from the illustration the piston valves are driven by a short throw crank and connecting-rod from an auxiliary shaft which could be driven by silent chain from the crankshaft. The inventor believes that by careful carrying out of the details of this design no material weight will be added while the advantages of the compressed air and piston valves will be obtained.

Design Has Possibilities

The novel idea in this motor is, of course, the suggestion that the piston valves should be used as air compressing pumps, and it is conceivable that on this account the engine might find some special sphere of usefulness. It would, like all piston valve motors, be rather expensive to make, and it would not be easy to get very large port openings.

For very large, heavy motors such as can be used for fire department vehicles or for boats would appear to be the most promising field of application at the moment, and the idea seems to have merit enough to warrant further investigation and experiment. It will be interesting to see if the motor succeeds in reaching the practical stage.



End and side sectional views through the piston valve motor invented by E. U. Stewart of Long Beach, Cal.

The FORVM

HOTCHKISS DRIVE ADVOCATED FOR HEAVIEST CLASS OF TRUCKS —EFFECT OF CONDUCTIVITY OF PISTON IN COOLING DISCUSSED

Hotchkiss Drive for Trucks

By A. M. Laycock
Chief Engineer Sheldon Axle & Spring Co.

EDITOR THE AUTOMOBILE:—At the present time, when live axles are being used so extensively for heavy motor vehicles, there is no more debatable point than the question of driving through the springs as against the use of radius rods and torsion members. Driving through the springs has been very successfully used in the pleasure car field for a good many years, particularly in racing cars, but in this discussion I would much prefer to confine my remarks to its application to worm gear design as applied on very heavy motor truck construction.

On the 1000-lb., 1500-lb., 1-ton and 2-ton sizes, it is generally conceded that this form of drive cannot be improved upon, but there is quite a little misunderstanding in regard to its application to 3-ton and 5-ton chassis and upwards. In the writer's estimation on the 3-ton and 5-ton class the forces acting on the spring eye are very much less in proportion than on the lighter vehicles, the speed factor being the important item.

In England, in the early days of the automobile, it was thought impossible to operate successfully any worm gear axle without the parallel radius rods and cantilever spring suspension as brought out by Lanchester on his first model, Lanchester at that time claiming that to work worm gears successfully there must be some parallel motion given to the axle which would at all times maintain a uniform velocity on the pitch line and cut down the unit pressure per square inch which was at that time the all-important consideration.

Then, as now, the successful operation of the worm was entirely dependent upon the retention of the oil film, particularly under high pressure, and unless the radius rods gave to the axle a parallel motion, as in the Lanchester suspension, the load came on the bronze gear with rapidly varying force as compared with a uniform pressure when the parallel motion was employed. Up to the present time in the United States there has not been a single adoption of the Lanchester suspension in its entirety.

The particular and all-important point of which designers in general have lost sight is, that the center line of the worm shaft must at all times be parallel to the center line of the engine power plant, which of course gives an equal angle to the rear universal joint as obtained on the forward one, transforming the uniform velocity into a variable in the propeller shaft and then changing it back into a uniform velocity (owing to the equal angles) and maintaining that uniform pressure which is so desirable in worm gear operation. The stresses created in some of our heavier 5-ton vehicles, equipped with radius rods and torsion members must be very high as compared with the sweet, harmonic motion of similar trucks equipped with the Lanchester drive.

Hotchkiss Drive Gives Parallel Movement

The point must be conceded, however, that very successful results have been obtained as regards the life of the worm unit, differential and the various parts influenced, but the question still remains—how much longer life would these same parts have if no radius or torsion members were used?

The illustrations as shown in Figs. 1 and 2 are anything but conventional designs, but the worm has been purposely underslung in order to describe and exaggerate the angles and bring out the points more clearly. In Fig. 1 you will notice there is no angularity whatever on the rear joint, but the torsion member tilts the rear axle up, generally pointing the worm shaft to the forward universal joint center. If the torsion member is raised somewhat and the worm shaft is tilted up more, one can obtain fairly satisfactory results, particularly when the eye of the torsion member is in the center of the propeller shaft longitudinally, for this also gives equal angles on both universals and so an unvarying worm velocity, but this construction has been very rarely carried out in practice.

It might be well to notice the action of the flat spring under load as this approaches very close to the Lanchester suspension, but cuts out its attendant complication. The prevailing idea at the present time is quite erroneous in regard to the front eye being the pivotal point and that the axis of the worm shaft moves around that point. The rear half of the spring always corrects the movement and imparts a true parallel motion within certain limits of deflection.

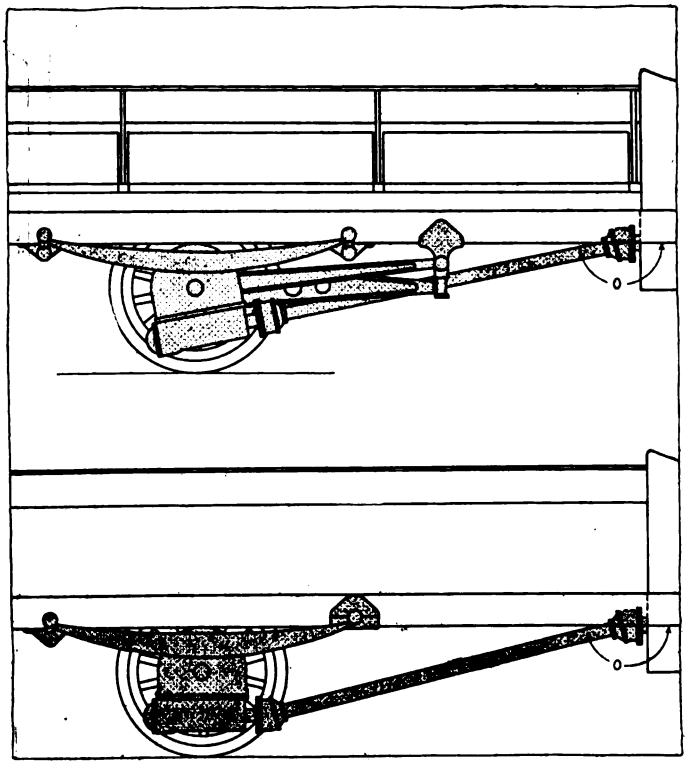
Springs Should Be Flat

In a good many designs abnormal cambers are used. This of course defeats the very object of driving through the springs, not only increasing the bending moment on the spring but upsetting the parallel motion to an alarming extent, particularly when the brakes are applied vigorously.

It is well also to note that in the Hotchkiss drive the spring seats attached to the axles are welded and not swiveled as in the radius rod and torsion member construction, which always gives more or less trouble particularly when operating in places exposed to mud and water, as it is most difficult to lubricate this bearing satisfactorily.

One of the greatest claims that Lanchester made for his parallel radius rod and cantilever suspension was the wear on tires. At that time, quite a few objections were raised in regard to the riding qualities of the Hotchkiss drive on account of the brake and torque reactions, but it is very interesting to note that this view is rapidly being changed. In the writer's opinion, the additional load put on from the brakes, and the torque reaction, assist very materially in dispensing with the use of the shock absorber, as the only time you need the shock absorber is when additional work is put on the spring, and this automatically increases the friction between the plates which naturally damps the effect of the spring.

Furthermore, by utilizing the Hotchkiss construction you have eliminated two spring seat bearings to take care of, two bearings on the torsion member, and four on the radius



Figs. 1 and 2—Diagram comparing torque arm with Hotchkiss layout

rod; and an additional two bearings on the springs, when the springs are suspended on links, together with the weight of all the parts named—a quite considerable item. Thus there seems everything in favor of driving through the springs on very heavy vehicles.

Analyzing Heat Flow

By E. H. Sherbondy

Consulting Engineer Clay & Sherbondy

EDITOR THE AUTOMOBILE:—Again reviewing the use of aluminum for automobile motor construction.

Mr. Leopold brought to light some interesting historical facts as to the use of aluminum for motor pistons and cylinders and to these I should like to add the following comments:

Interesting Historical Facts

In 1902 Alexander Winton of Cleveland built a racing car having a two-cylinder opposed crank motor in which he used aluminum cylinder heads and later in 1903 he used aluminum heads in the racing car "Bullet No. 2." During 1904 the German Daimler company built some large high-speed gasoline motors, after the designs of Loutski. These motors were six cylinders of 12-in. bore and 7½-in. stroke running at 900 r.p.m., developing about 1500 b.h.p. They were equipped with aluminum pistons and this is the earliest application within the writer's knowledge. These motors were designed for the use of submarines.

About 1905 Emile Mors brought out a design for a four-cylinder motor of 105 mm. and 150 mm., which comprised a number of novel features in design, among others, cast-iron sleeves pressed into aluminum jackets. The cylinders were T-head valve arrangement, cast in pairs, and the external appearance was very similar to that of the conventional iron cylinder design. I believe the St. Louis Car Co. produced a limited number of these motors under license. Prior to the general advocacy of aluminum pistons in America many French engineers had considered the subject.

In 1909 the Tony Huber Peugeot motors submitted to the A. C. F. were equipped with aluminum pistons.

A French engineer and writer, A. Contet, has given some comments on aluminum pistons, showing comparative power curves of the same motor using aluminum and iron pistons. These power curves indicated that there was a slight rise in mechanical efficiency as would be expected by reducing the inertia forces, however, his consideration of the subject at that time was superficial. I was told some time back that Chenard-Walcker and Doriot, Flandrian, Parant have been using aluminum pistons continuously since 1910 with good success in small motors (80-90 mm. bore).

Engineers Are Hasty

In the case of aluminum pistons which are now in vogue commercially I find the majority of engineers with whom I have talked on this subject have not carried out comparative tests in the same motor with iron and aluminum and plotted the resulting torque and horsepower curves, but have gone over to the aluminum piston in new designs on the strength of superficial considerations, aluminum being the fashion as is the case of many details of motor-car construction which are not settled on by reason of their engineering value but rather conforming with some powerful precedent which has been established primarily as a result of commercial consideration. Some of the older engineers in the industry, who have had the widest possible experience are not yet sold on the aluminum piston proposition for commercial product.

Peugeot, Talbot, Sunbeam, Mercedes and a great many other firms well known and established purely because of their engineering ability, have more than a passing knowledge of the materials of construction they employ. Peugeot was carrying on experiments with aluminum pistons in 1909. Chas. Faroux of *La Vie Automobile*, told the writer that the Peugeot practical results were within 2 per cent in all particulars of calculations on which the designs were based. Certainly these European firms have shown far more originality, initiative and independence of thought than has been exhibited on this side of the water—and the only logical deduction is that they are better students of engineering than we are over here. Certainly you will not find them buying American cars to cut to pieces and see how the trick is done. To make a long story short, we don't diagnose the disease before we take the cure but join the motley crew because it's the thing that is "being don."

It has been repeatedly asserted, by some of those interested in this field of work, that the increased conductivity of aluminum over iron was a factor of great importance in the dissipation of heat from motor cylinders and pistons and in my former communication, I perhaps did not bring forth my views on this point in as clear a manner as might be desirable. However, I believe the following may be stated axiomatically. "The dissipation of heat necessary and unavoidable in an internal combustion engine is controlled by the initial and final heat elements," *i.e.*, the temperature, coefficient of conduction, convexion and radiation of the gases of combustion at a higher level and the temperature coefficient of conduction, convexion and radiation of the cooling water or air, as the case may be, at a lower level. The coefficient of radiation in gases undergoing combustion is as yet an indeterminate factor having been a matter of experiment and consideration by Clerk, Callendar, Hopkinson and others. See the magazine *Engineering* (British). The coefficient and conduction of gases in general is very low, varying with the density of the gas employed (about 1/14,000 that of copper). The coefficient of convexion depends upon the internal agitation of the gases of combustion at one end and the rate of circulation of the cooling water at the other. It should be noted that liquids in general have a very small coefficient of conduction and that the transfer of heat through a liquid takes place almost altogether by convexion and is merely due to the agitation of the liquid molecules.

According to Dr. Watson of the Royal College of Science (London), who has done so much good work carrying out complete motor tests, the conductivity of aluminum is a little more than twice that of iron, namely, 0.344 cal./cm. sec. for aluminum and 0.167 cal./cm. sec. for iron. In the case of the aluminum cylinder where the wall proper is of this material, the heat passing from the gases of combustion by means of radiation and convexion to the cylinder wall is carried through by conduction at twice the rate of speed occurring in the iron cylinder. This heat must be carried away from the wall—to prevent an undue rise of temperature—by the cooling medium, and the rate at which this is done depends only the temperature of the cooling medium and its rate of circulation, so that we see in this case at least the conductivity of the metal employed has no effect upon the regulation of the working temperature in an internal combustion engine.

In the future development of automobile engines, aluminum cylinders may be an important factor in reducing the weight and it is very probable that satisfactory designs will be worked out, but the sole advantage will be weight reduction and not some startling thermo-dynamic change.

Due to its great affinity for oxygen when molten, aluminum, when cast, is usually porous, and if used in cylinders, there is likely to be a large percentage of bad castings because of water leaking through the jacket chamber to the bore. This may be overcome by designing the cylinders so that the inside of the jacket and the cylinder wall can be painted with litharge.

Favors Inserted Sleeve

Probably the best way of using aluminum to advantage in an automobile motor is to cast the cylinder jacket and crankcase integral, to insert cast-iron sleeves to form the cylinders proper in much the same fashion which is used in large gas engines so that the cooling water comes into actual contact with the sleeve. In general this construction would necessitate a loose head.

In reply to Mr. Leopold's comments on my earlier communication.

It is, of course clear to anyone informed on elementary physical processes, that the transfer of heat from one portion to another of a continuous metallic body takes place by the vis-viva or living force of the molecules of that substance, which cannot change their position relative to the aggregate in which they are found but only their amplitude of vibration. This phenomenon is called conduction.

In my former communication I pointed out that the heat of the piston was carried off "mainly by convexion to the lubricating oil film." It, of course, is apparent that the heat must flow from the piston head proper to the side walls and that sufficient material should be supplied in the design and construction of a piston to attain this end. Now, as pointed out in my earlier article, the only two exits of importance for the heat residing in the piston is by the way of the lubricating oil film, or the cylinder wall proper where the oil film breaks down—and the crankcase air. Some of the piston heat is given up to the gases of combustion but a technical analysis of the interchange of heat between the gases undergoing combustion and the cylinder walls, involves the use of mathematics and is too complicated to be presented in these brief comments.

The heat must be carried off to the crankcase air by convexion and radiation, and as the crankcase air is always heavily laden with oil in various states of disgregation from large liquid drops to vapor, we have an added agency of importance. The coefficient of radiation of cast aluminum is rather low, and the heat given up in this manner should be accounted negligible. There remains one method of carrying the heat from the piston—convexion—which depends on the rate of circulation of the cooling medium. The rate of air circulation on the inside of the piston is not rapid unless some special construction is used to obtain a flow of air into and out of the piston. To this end the writer applied for and obtained patents in connection with other motor improvements some years ago. The German Daimler Co.—I believe through Paul Daimler—also have issued patents on means for circulating air on the interior of pistons. This work was carried out in both instances with a view to enabling large engines to run at very high speed, without running up the inertia pressures to unreasonable values, which would have occurred with water-cooled pistons.

Factor of Crankcase Air

The importance of the nature of these considerations relative to other factors at play in internal combustion engines appears rather small. It would be somewhat difficult to determine just how much heat of the total amount received by the pistons passes to the crankcase air but it would be my guess that the percentage would be very much less than that passing by way of the cylinder oil to the cylinder walls. There is, of course, plenty of data available in the case of water-cooled pistons, such as are used in larger work than we are considering at present. In conclusion of these remarks on the importance of the coefficient of conduction of the material employed, I can only hold to the deductions which seem inevitable, in view of evidence presented by a consideration of the physical processes involved.

In relation to the consideration of inertia pressure, I think my position on this matter was clear enough.

In review: I hold that the inertia pressure occurring in the commercial product issuing from motor car factories today is not a matter for serious consideration and that cast iron is certainly as satisfactory and far cheaper than any other material which may be employed for pistons in touring car motors. As Mr. Lawrence Pomeroy (Vauxhall Motors) puts it "when a motor gets up to 3000 r.p.m. or so, the average customer gets so thoroughly frightened at the job that he is glad to take his foot from the accelerator," and this is the point worthy of consideration above all others. However, I shall make the high-speed engine a matter for consideration in another article.

In reference to Mr. Diamond's comments: Mr. Diamond's point, namely, "that the diffusion of heat through the aluminum pistons is more rapid than cast iron," goes of course, unquestioned, and in my former article I touched on only a few of the high spots of this subject, which came to my mind in the short period at my disposal, at that time. I must, however, refer to my answer to Mr. Leopold in answer to the points at issue and in conclusion admit that I have no axe to grind other than the advancement of automobile engineering.

Twin-Six Balance

—

By D. Fergusson
Mechanical Engineer, Pierce-Arrow Motor Car Co.

EDITOR THE AUTOMOBILE:—I am sorry I did not have an opportunity of seeing Mr. Vincent's letter before mine was published. It would have admitted of my altering my letter slightly and would have done away with much of Mr. Vincent's argument. Will you please insert in your next issue that I wish to add the following postscript to my letter published in your issue of Oct. 28, 1915?

"To the loads due to the inertia of the pistons and the reciprocating parts of their connecting-rods, must, of course, be added the centrifugal force due to the rotating parts of the connecting-rods. I assume that the same standards of engineering practice are used in both the six- and twelve-cylinder types."

The History of the American Automobile Industry

Second Installment of the Complete History of the Industry in America, the Opening Installment Appearing in Last Issue —Complete History To Be Published Later in Book Form

This Week the Conception and Early Development of the Steam Vehicle, the Pioneer in the Automobile Field

By David Beecroft

THE year 1769 is to the history of steam automobiles what the year 1492 is to America. In 1769 Nicholas Joseph Cugnot, a Frenchman, built the first steam locomotive, which was a three-wheel vehicle. The next year Cugnot built a more perfected type of vehicle by means of State funds appropriated for the purpose, and a model of this vehicle is still in Paris. True, it was a crude affair, scarcely possessing a single feature that could be compared with the vehicles of to-day, yet it incorporated many of the basic features of the present-day steam engine, even if they were in forms that can scarcely be recognized, and handled a boat of 2.5 tons at 3 miles per hour. Cugnot used a bowl-shaped boiler that hung out in front, ahead of the single-drive wheel, the boiler being over 4 ft. in diameter. A fire beneath it supplied the requisite heat; and the steam was alternately conducted to two cylinders by means of a four-way cock. The cylinders were placed vertically above the single drive wheel and power was conveyed to the wheel by means of two ratchet wheels in connection with a system of pawls and rods. Cugnot steered by the single driver and so was spared the difficulties of solving steering, differential gears and other later problems. The frame was a stout wood one, which rested at the rear on the back axle with its wheel on each end and in front it joined an iron frame carried in bronze bearings on the axle of the driving wheel. Such was the pioneer steam vehicle.

If the honor of building the first steam vehicle goes to Cugnot and France the honor of making a steam vehicle possible must go to James Watt and Scotland. James Watt was a prominent engineer, who had been watching the crude steam engines that were used for pumping water in mines, these cumbrous affairs dating back to 1698, when they were first made practical by Thomas Savery, a Briton, to whom belongs the honor of being the first man to harness the power of steam to any useful practical device, as previous to that time steam was centuries old, but it had only been used in toys and for a few minor tasks.

The Savery engine had been improved by Thomas Newcomen, a Scotchman, in 1705, whose engines were the recognized designs from that time until 1763, when Watt made his great improvement on them. Watt saw that the Newcomen engine, explained later, was exceedingly wasteful of fuel and impossible of general adaptation. To improve its economy he conceived the separate condenser for the steam, and by this one invention gave us the condensing steam engine as we have it to-day and made it possible for steam to be adapted to vehicles and a myriad of other uses. Thus Watt, by this master stroke of genius, gave practical birth to the steam engine just as in 1876 practical birth was given to the gasoline engine of to-day by introducing the compression of the explosive mixture, which made it a reality.

It was by virtue of Watt's patent granted in 1769 and which expired in 1800 that Cugnot was able to make his first steam locomotive. But Watt did immeasurably more, in a few years he had invented the centrifugal governor, which is continued until to-day. He established the law in steam that the cylinders must be kept as hot as the steam entering them; he conceived the employment of the expansive power of steam in the cylinder; previous to his day water had been used to make the pistons steam tight, but Watt invented the packing as we have it to-day.

Although on Watt's shoulders rests the mantle of Father of the Steam Engine, we must not imagine his engine similar to ours of to-day. At that time the crankshaft as we know it to-day was unknown, and it was not until 1780 that the crankshaft was first used in an engine by Pickard. Previously various rod-and-ratchet devices were used.

After Cugnot's steam vehicle was running, activity in developing steam road locomotives, as they were then called, was rife in France and England, but no radical improvements were made until 1802, when Richard Trevithick, in England, built the first practical steam vehicle in that it incorporated so many of the features that time has proved are necessary in the steam vehicle as we know it. Trevithick built a steam engine with a crankshaft, as we know it to-day, in gasoline vehicles as well as steam automobiles. This crankshaft carried a flywheel; and Trevithick went further by connecting the crankshaft by gearing with the driving

road wheels. This Trevithick automobile made many journeys at speeds of 10 miles per hour, an amazing performance for 113 years ago. It was sold after being in use for 3 years to a hop rolling mill, where it furnished the motive power for many years. Trevithick must receive the honor of being the first inventor to transmit power from the motor to the drive wheels through a chain of gears, as well as being the builder of the first practical steam automobile.

The third big forward step in developing steam automobiles came in 1821 when the first steam vehicle that afforded comfortable accommodation for passengers was built. Cugnot gave us, in 1769, the first steam vehicle; Trevithick in 1802 gave us the first practical steam automobile and the honor of the first steam vehicle designed with the object of giving some comfort to the passengers it carried goes to Julius Griffiths of England. The body resembled that of a stage coach and was hung on springs and the boiler and motor were mounted on a special frame in rear of the coach body. A chain of gears connected the two-cylinder vertical motor to the driving wheels on the rear axle. The driver sat separately over the front axle, which was used in steering. Griffiths used an engine that condensed the used steam in a set of thin tubes and returned the water to the boiler for repeated use.

In this History of the Automobile Industry in America it is imperative to trace the evolution of steam and the steam vehicle from its inception in those countries where it was developed. Turning next to America, before completing the stage of progress abroad, it must be remembered that carriages and workmen were not plentiful in this new country at the time of the War of Independence.

The first steam engine in America was set up in a copper mine near Belleville, N. J., in 1753, at which time steam-engine construction could not have been very familiar to American inventors because of the large territory and the imperfect means of communication. In spite of these things Oliver Evans (1755-1819), a celebrated American engineer and millwright, turned his attention to the propulsion of road vehicles about 1772. In 1786 he petitioned the legislature of Pennsylvania for the sole right to use his steam engine in that State and was thought insane, an unjust accusation too often extended to many of his successors. Maryland, however, although probably thinking the same, granted him a patent for 14 years, dating from 1787. Another American inventor, Nathan Read, took up the steam automobile problem in 1788, 1789, and in 1790 applied for a patent for his invention.

Just which of these two inventors actually did the first work seems not to be known. Read obtained a patent for a multi-tubular boiler in 1791 and must therefore be given much credit by those who followed after him because of the greatly increased heating surface obtained by this construction with consequent faster steam generation and very greatly reduced size and weight. Whether or not this invention had much bearing on later work is not known. It may be that it was too early to be appreciated and so remained in obscurity until nearly a century had passed. Read proposed to use two double-acting engines, one driving each wheel so that in turning, each engine would respond to the slower or faster movement of the wheel. He also proposed to exhaust the steam rearwardly and thus take advantage of the reaction to assist in propelling the carriage. It seems not to have been then understood that in order to secure any satisfactory advantage from the reaction of an escaping jet of steam or other fluid, the moving part must be traveling very nearly half as fast as the motion of the escaping fluid. The reaction from a jet of escaping steam is very slight in its effect on a slow moving vehicle. He also applied his device to boats.

An Amphibious Vehicle

To Evans is usually given the credit of priority at this period for not only did he apply for patents in Pennsylvania and Maryland, but during his life he constructed a number of steam engines and made many attempts to secure capital for his steam carriage projects. Finally in 1804, while fitting up a steam harbor dredge for the City of Philadelphia he decided to make it self-propelling, and says, "This was a fine opportunity to show the public that my engine could propel both land and water carriages, and I resolved to do it. When the work was finished I put wheels under it; and though it was equal in weight to 200 barrels of flour, (about 20 tons) and the wheels were fixed on wooden axle trees for this temporary purpose, and in a very rough manner, and attended with great friction, of course, yet with this small engine, I transported my great burthen to the Schuylkill with ease; and, when it was launched into the water I fixed a paddle-wheel at the stern and drove it down the Schuylkill to the Delaware and up the Delaware to the city, leaving all the vessels going up behind me at least half way, the wind being ahead."

From the above account it would seem that this was his only self-propelled experience. The load was exceptionally heavy. The distance, however, was but 1½ miles, the streets probably good and the speed unquestionably slow. It was, however, a very creditable showing both on land and on water and compares very favorably with the work of others at or near that time.

It must be kept in mind that there was very little vehicle traffic at that time. American stage coaches began running in 1786 and then only between the more important centers. The rivers were the principal means of communication outside of private conveyances. Practically everyone was compelled to depend upon his or her own conveyance, although as far back as 1697 John Clapp at the Bowery, New York, kept a hackney coach for the convenience of patrons. It is an interesting comment on the tendency of the people to hold back progress by restrictive laws that in 1699 a law was passed in New York against fast driving of "slees" (sleighs). Words would probably not express the horror of those ancient law makers if they have been transported into modern with its never ending streams of rapid

Stating the Case for the Eight

Comparing Eights with Twelves Shows Many Advantages for Simpler Type—Comparative Figures for Balance and Efficiency

By Charles S. Crawford*
Chief Engineer Cole Motor Car Co.

THE required range of ability, *which in substance means the capacity of the engine to do the ordinary thing and to answer everyday requirements*, is that which can be utilized in practice, and a speed range that will give a car from 2 to 60 m.p.h. in high gear, is, as we all know, ample.

The desirable torque must be maintained throughout the useful speed range, and this the eight-cylinder engine does.

This range of capacity depends upon the ability to run the engine to reasonably high speed without detrimental vibration and to arrange the gear ratio in relation to the highest speed that can be developed with a maintenance of torque.

To illustrate this: If an engine running at 2600 r.p.m. can, with a given gear ratio, make a car go 60 m.p.h., then the necessary size or displacement of the engine can be determined by the torque necessary to reach this speed in a given time, or with a given acceleration, say, of from 10 to 50 m.p.h. in a certain number of seconds.

This will then utilize to advantage all the power the engine can develop at its highest useful speed, which is limited by the volumetric efficiency at the said speed, or the ability to maintain a proportional torque. To attain this result is simply a matter of design and the proper development of the power plant.

Fundamentally, the torque developed is dependent on the displacement and the mean effective pressure on the pistons. Given a full charge in the cylinders by volume, this pressure is proportional to the energy of the mixture.

To illustrate this point more clearly: There is a certain mixture of gasoline and air which, with normal quality of gasoline, is about one to fourteen. This is the most efficient from the point of perfect combustion, which means that the energy which we derive from it on its combustion is a maximum consistent with the heat energy in the fuel.

It is possible to increase the explosive pressure by an increase in the strength of the mixture, that is, an increase in the heat energy of the mixture, and this can only be accomplished by having the maximum weight of gasoline and air.

We might have the best of volumetric efficiency from a valve-timing viewpoint and yet the heat energy of the charge would not be a maximum if it were of too high a temperature or partially expanded before entering the cylinder.

Excess compression of the charge in the cylinders does not add to the pressure. We still have the same quantity of heat units in the mixture and by excessive compression we do not increase these. More work is done on the compression stroke, and though the initial pressure is higher there is no net gain in work on the crankshaft.

Thus it follows that the chief advantage of increasing the compression is to obtain rapidity of ignition at high speed and not to increase the torque at low speed. With an eight-cylinder engine, properly designed, we secure every advantage necessary for practical purposes, therefore, without incurring the danger of trouble by going beyond that point. *The torque developed in an eight should be and is greater than that of a twin-six with the same displacement, for there is a greater heat loss with an increased number of cylinders.*

The area of cylinder wall exposed is proportionately greater, the displacement being the same, and when it is considered that approximately 60 per cent of the heat energy of the fuel is lost through the cooling water and radiation, the fallacy of too great a number of cylinders with a consequent decrease in individual cylinder displacement becomes evident, while the presumption that, by reason of the small bore and increased compression it is possible to increase the available torque, also, is shown to be fallacious.

Engines with small bore and necessarily high compression, while being advantageous at the very high speeds, invariably give unsatisfactory operation at lower speeds, and it is always necessary to retard the spark in order to prevent knocking. It follows, necessarily, therefore, that the eight, with its larger bore and consequently lower compression, is bound to possess advantages in this respect and *must of necessity give a smoother operation at the lower speeds.*

Acceleration and Torque

As we have defined the desirable range, we can assume that with the engine running at 2565 r.p.m., in order to get a road speed of 60 m.p.h. with 35-in. wheels, eliminating slippage, a gear ratio of 4 5/11 to 1 is required. From this basis, establishing a definite acceleration, the necessary displacement of the engine to get the torque essential, can be determined.

In the light of the performance of powerful multiple-cylinder cars, the acceleration of from 10 to 50 m.p.h. should be accomplished in from 20 to 25 sec.

Cole eight stock jobs well run in, carrying three passengers and with windshield and top up, will give an acceleration of from 10 to 50 m.p.h. in from 22 to 24 sec. The motor has a piston displacement of 346 cu. in., giving a maximum torque of 187½ ft.-lb.

The horsepower and torque curve of this engine is shown in Fig. 1, while in Fig. 2 is shown the torque developed per cubic inch of piston displacement. Incidentally, the torque developed per cubic inch of piston displacement of a twin-six engine is also shown in Fig. 2.

In this figure *A* represents the curve of the eight-cylinder engine, while *B* designates that of the twin-six under similar conditions.

The torque in the eight is conventional, inasmuch as the most efficient speed is in the neighborhood of 1000 r.p.m., which corresponds to 750 ft. per minute piston speed. This is only what could be expected, for at this speed the gas velocity is at a maximum, consistent with the manifold friction, while the volumetric efficiency is a maximum, by reason of the relation of this velocity and the time element of the valve openings. The temperature at this speed is consistent with good thermal efficiency, and the relative curves show, also, where the cooling theory has its effect on the thermal efficiency.

At the lowest speeds it is virtually impossible to have a greater torque than at any other speed if a normal torque is developed at the usual speed of maximum torque, because the

*From a paper read Oct. 29 before Indiana Section S. A. E.

gaseous inertia, on which we rely to a great extent to fill the cylinders, has not reached a point where it can overcome the skin friction of the manifold, the port and the valve openings, and still maintain a reasonable velocity.

These statements and those which immediately follow will correct the assumption left with us on a previous occasion that, by reason of multiple cylinders, it is possible to get the maximum torque at the lowest speeds of revolution.

Since the torque is proportional to the horsepower and speed, and therefore can be deduced from a factor which is constant, it is difficult to see how it would be possible to obtain from horsepower curves which are similar in characteristics torque curves which are so widely different at the lower speeds. Yet this is precisely what is inferred from the characteristic curves of single-six and twin-six engines of approximately equal capacity, brought previously to our attention.

The torque frequency has no influence on the magnitude of the torque developed at lower speeds. However, the ability to attain increased volumetric efficiency and better distribution of the charge is responsible for the actual increase that does occur.

Where the eight scores in generating increased torque at lower speeds is in its undoubted ability to distribute the mixture to better advantage. In support of this contention a layout of the manifolds to scale is shown in Fig. 3, which presents clearly the equidistant port locations and the comparatively short distance of each from the carbureter.

The importance of limiting the manifold lengths to obtain good volumetric efficiency and likewise torque at the lower speeds being obvious, the ability of the eight's construction to give this condition stands out prominently, and is thus seen to be more pronounced than in any other type of multiple-cylinder engine.

The efficiency of the carbureter, by reason of constant jet suction, is logical in the eight, while the suction strokes if closer together, as in the twin-six, produce an excessive lap which creates at some point almost double suction in the manifold.

In regard to frequency of impulse it is asserted that the frequency is proportional to the number of cylinders. The actual frequency at the road wheels is the *determining* factor, however, and this is dependent on the gear ratio.

Unbalance and Vibration

Smoothness *from the point of engine balance* is the next point that requires study. In the conventional fours there are, from their inherent design and construction, unbalanced forces due to inertia, which increase with the square of the speed. This unbalanced force is fundamental in the four but not necessarily in the eight, as is commonly supposed.

While the forces do occur as calculations show, there must be a fair amount of discrimination in discussing the relative balance of mechanisms that have respectively unbalance and perfect balance, viewed theoretically.

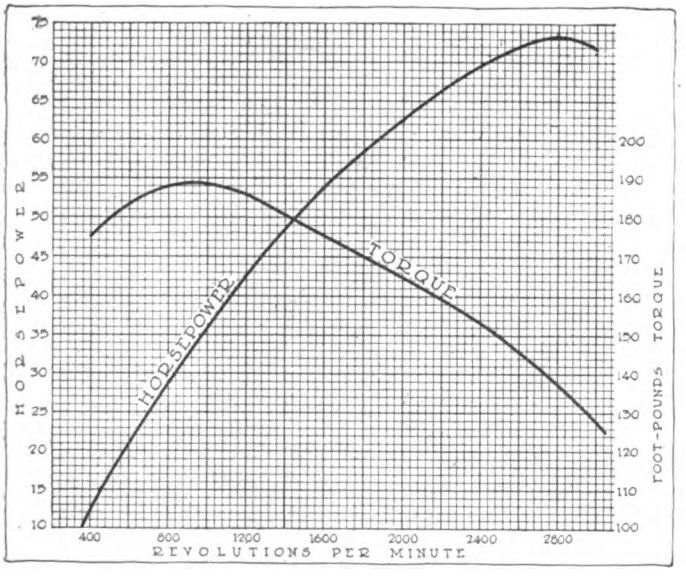

Fig. 1—Power and torque curves of Cole eight

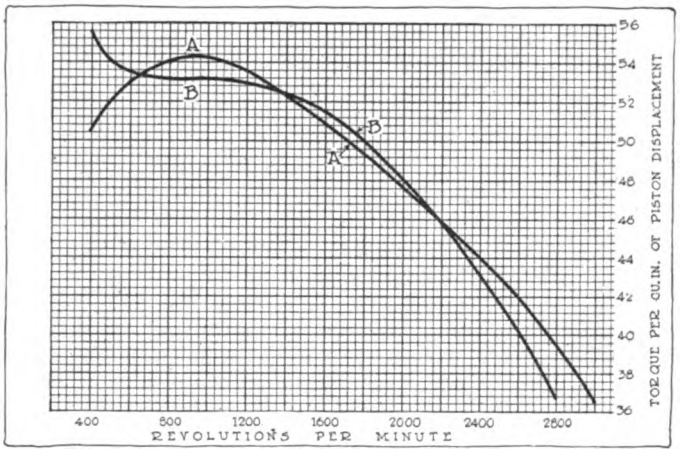

Fig. 2—Torque per cubic inch piston displacement for Cole eight and also a twelve-cylinder engine. A is the curve for the eight and B that of the twelve

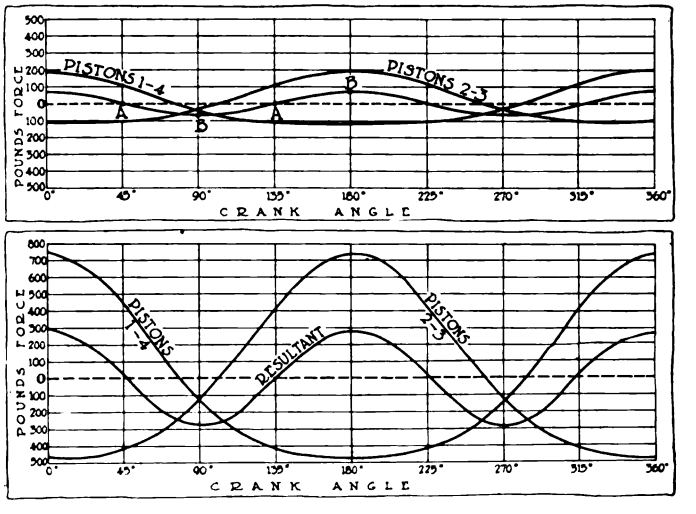

Figs. 4 and 5—Unbalanced force fluctuations in an eight-cylinder engine. Upper—at 1000 r.p.m. Lower—at 2000 r.p.m.

There are two fundamentally distinct problems in connection with vibration and balance. There are the vibrations that arise from unbalanced systems, considering all the parts as rigid within themselves, and vibrations or sources of vibration due to the elastic yielding or springing of the parts of the system—such as the crankshaft, which is subject to bending and torsion; the connecting-rod, which acts as a strut and obeys the law as such in connection with rigidity, and sustaining members, such as the engine crankcase.

The vibrations arising from lack of rigidity in the crankcase can be attributed to the influence of the forces on either side of the plane of symmetry.

Supposing the engine were articulated at the middle, or plane of symmetry. We can see that each half would rock against the other in a symmetrical manner, influenced by the couples exerted by the centrifugal and inertia forces on the crankshaft.

The stress of the crankcase section at its middle point, therefore, resists this tendency, the magnitude of which increases with the length of the crankshaft and crankcase,

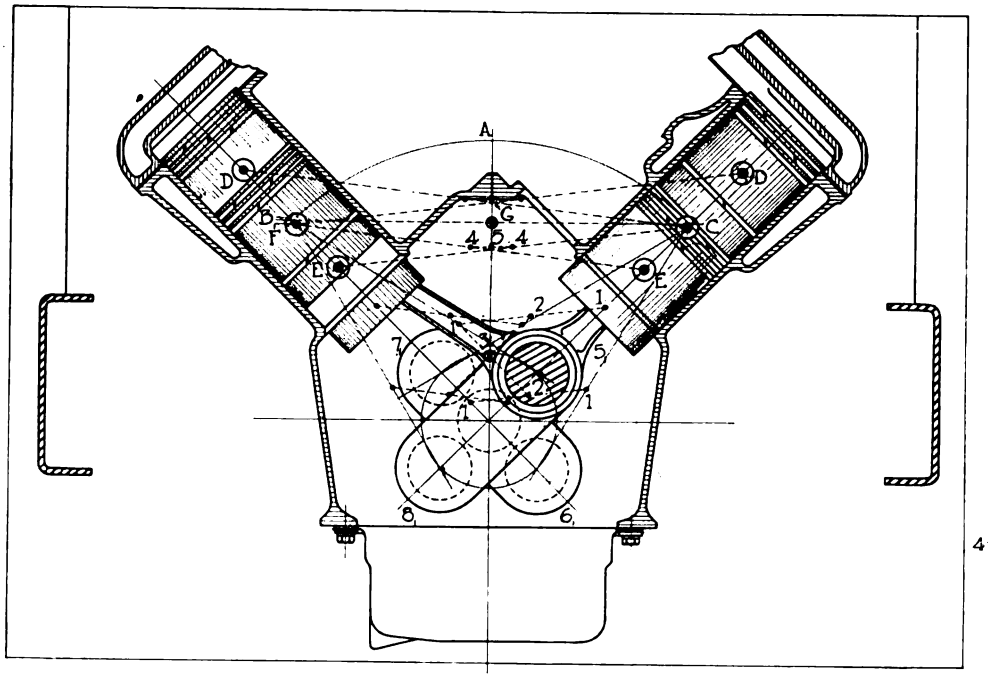

Fig. 8—Relative piston positions and mass center movement in eight with 90 degree crankshaft

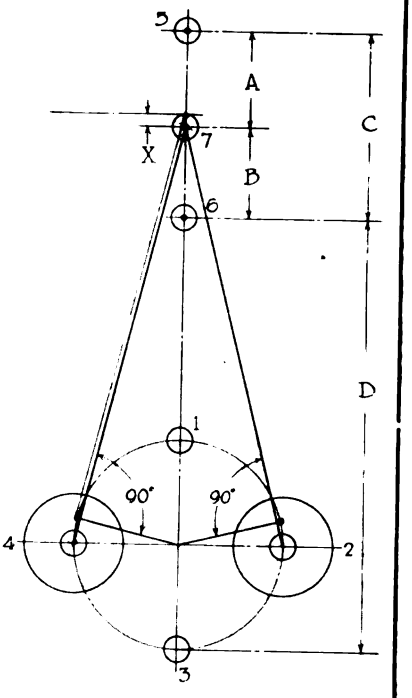

Fig. 6—Diagram of piston mass center movement in single cylinder

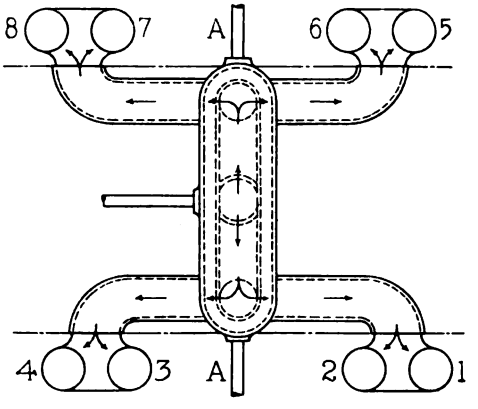

Fig. 3—Intake manifold layout of eight

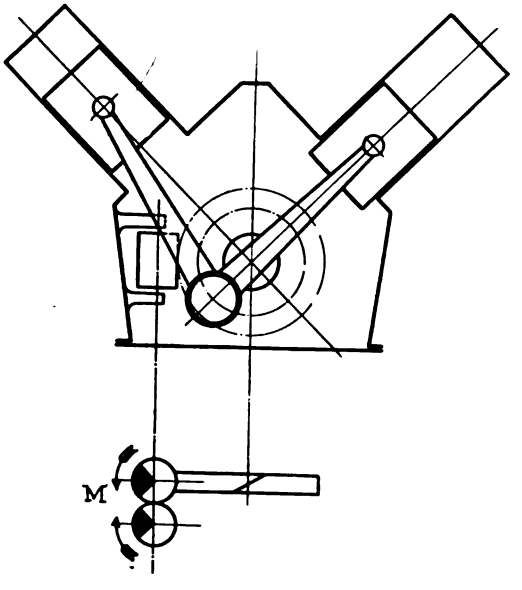

Fig. 12—Lanchester anti-vibrator for neutralizing horizontal unbalanced force

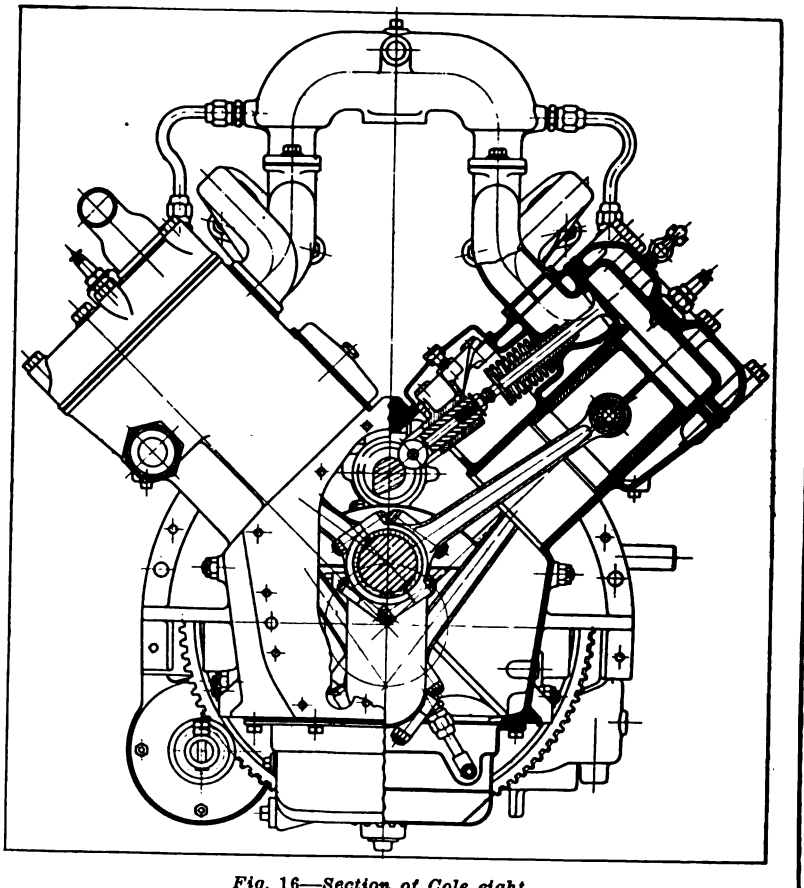

Fig. 16—Section of Cole eight

and an absence of rigidity, therefore, would result in a vibratory bending of the engine itself. The shortness of the crankshaft and crankcase and consequent rigidity of the eight, therefore, is distinctly favorable.

Likewise, the counterbalancing of the crankshaft eliminates to a marked degree the couple due to centrifugal forces and therefore the vibratory tendency is practically expelled. So far as the inertia unbalance of the eight is concerned, it is advisable to consider this, to some extent, to show that this is not objectionable. At the outset it would be wise to remark that while the horizontal vibratory force does exist, one is usually surprised at not being able to notice it when riding in an eight-cylinder car.

In order to show the actual magnitude of this vibration tendency at different speeds, curves labeled Fig. 4 and Fig. 5 are shown. Fig. 4 represents the magnitude of the unbalanced forces of the pistons in each block at 1000 r.p.m., and, as will be noticed, they are very small. Since this is the normal running speed, it explains the reason why vibration in the eight is not perceptible.

That this is true is more evident when you consider the effect of a force of this order acting upon the mass of the engine and the chassis. Imagine, for instance, applying a force of 70 lb. on a mass weighing 3500 lb., suspended on springs, by starting with zero and gradually increasing the force to the maximum in a time space corresponding to the periodicity of the revolutions. You could not feel it and this is exactly the condition that exists in the curve shown. At point *A* there is no force, but it is applied almost uniformly up to the maximum of 70 lb. at point *B*.

At 2000 r.p.m., which is a high rate of speed, and one not used for long periods, the forces increase as shown in Fig. 5. The forces plotted are the actual magnitudes as calculated for a 3½-bore motor with aluminum pistons.

It has previously been shown why this unbalanced condition exists, but in order to give a better idea and to elucidate more logically the points to which reference is made later in the paper, I have added diagram, Fig. 6. The four positions of the crankshaft are shown respectively, at 1, 2, 3 and 4, while 5 and 6 are the top and bottom of the piston stroke, respectively, point 7 being at the position of mid-piston travel. If the connecting-rods were of infinite length all four pistons would reach mid-stroke position at the same instant and at all other points, pistons 1 and 2 would have the same motion as pistons 3 and 4. With the connecting-rod of finite length, however, the positions of mid-stroke and mid-crankpin travel do not coincide, the error being as shown at *X*.

Now the inertia of the piston masses, or the energy stored in them, tending to keep the pistons in their state of motion, is dependent on the velocity or acceleration and the mass. As will be observed from the diagram, owing to the angularity of the connecting-rod and the position of the pistons at mid-crankpin travel, piston No. 4, traveling upward, will have farther to go than half-stroke by the amount *X* or a total *A*, while the piston going down will have less than half-stroke by the amount *X* or the distance *B*, to travel in the same time, which is in 90 deg. of crankpin travel. Therefore, the speed on the up-stroke of the piston will be greater than on the down-stroke, which explains the difference in the inertia of the piston up and down respectively. This is the magnitude of the inertia unbalance and has the effect of an external force equal to the difference of inertia of the pistons up and down.

The longer the connecting-rod the less will be the variation *X*, but the amount that this variation can be reduced is very slight unless the connecting-rod is impracticably long. The limit of length is determined by the rigidity sought. The longer we make the connecting-rod, the more substantial it must be to give the same rigidity as a connecting-rod of shorter length, and then weight becomes a factor to be considered.

So far as the influence of inertia on bearing wear is concerned, this will be the same whether it is a four, six, eight or twin-six engine, if the masses are equal, as the influence of inertia, or the accelerating force of the pistons on the crankpin, is independent of the balance of the masses as a whole.

The main bearing loads set up by the centrifugal effect of the crankpins and connecting-rod bearings are quite appreciable. In order to reduce these to an absolute minimum a counter-balanced crankshaft is used in all of our engines.

The counter-balances as shown in Plate 13 are effective because they counteract the effect of the centrifugal forces, and incidentally the balancing of the revolving masses as nearly as possible in the planes of rotation also has a remarkable steadying effect on the shaft as a whole, and eliminates to a marked degree local distortion of the shaft, thus preventing the periodic tremors that often exist as a result of this local deformation.

As a means of comparison of the bearing pressures due to the influence of inertia and explosion forces, refer to Table 7. It will be seen that actually in the eight-cylinder engine we have relatively less pressure on the connecting-rod and main bearing.

The relative balance of the six and eight has been illustrated in a previous paper before this section, and though it was asserted that the eight-cylinder engine is not a balanced system, I should not say that this statement was fundamentally in accord with the most recent scientific conclusions along this line.

In the course of our experiments made as a means of determining the influence of the theoretical unbalance of the conventional eight, we have experimented with various types of crankshafts designed to eliminate it and make a "system of bodies," or a theoretically balanced system, the same as we find in the six and twin-six.

Fig. 8 shows an end view of one of the shafts in question, the crankpins being at 90 deg. to each other. This demonstrates graphically the balance of the piston masses and the reciprocating portion of the connecting-rods. The angular location of the pins with respect to each other in the longitudinal plane and the effects thereof are shown later.

This illustration is made primarily to prove that an eight-cylinder V-type engine is not necessarily an unbalanced system. In the drawing it will be seen that the shaft is in dead center position. It will be observed that one piston is up and one down respectively, while two are in the position of mid-crankpin travel.

The same is true of each block and therefore the center of gravity will coincide in each block at any instant, the arc *A* struck from the center shaft passing through the center of gravity *B* and *C* as shown. The center of gravity of the pistons is indicated by the black spots in the line of piston travel. The positions *B* and *C* are midway between the center of gravity or mid-position of the pistons *D* and *E* and the center of gravity *F* of the other piston. Likewise, the center of gravity of the connecting-rods is indicated by the small dots on the center line of the connecting-rods as shown at 1-1.

The points 2-2 show the common center of gravity of the rods on the same crankpin, of which point 3 is the combined center of gravity of the whole and is common to all the connecting-rods and on the vertical center line of the motor.

The points 4-4 are the common centers of gravity of the piston masses on each crankpin, being midway between the center of gravity on each piston, the common center of gravity of each system being indicated at point 5, while *G* is the combined center of gravity of the whole system and coincides with the center of gravity of the pistons in both blocks as arrived at by the combination of the centers of gravity *B* and *C*. This, therefore, is an analogous condition to that of the six-cylinder engine.

As a further illustration and as a comparison with a conventional shaft, the existing inertia and accelerating forces are again plotted as shown in curves in Fig. 9 and Fig. 10. The inertia curves being superimposed at crank periods of 90 deg., the resultant is zero, as indicated at 0-0. This is arrived at by subtracting all the negative ordinates, or those beneath the zero line, from the positive ordinates above the zero line.

Figuratively we can arrive at the same conclusion by resolving the forces of inertia and acceleration of each piston into horizontal and vertical components. It will be seen in Fig. 8 that the piston masses 6(1) and 7(1) each have their resultant downward as the piston 6(1), having passed the position of maximum velocity, the energy of the piston will be doing work on the crankshaft while the piston 7(1), not yet having reached the point of maximum velocity, is still being accelerated by the crankshaft, its reaction being, therefore, downward. Adding up the forces we get zero as a resultant, showing that there is positively no resultant unbalanced force.

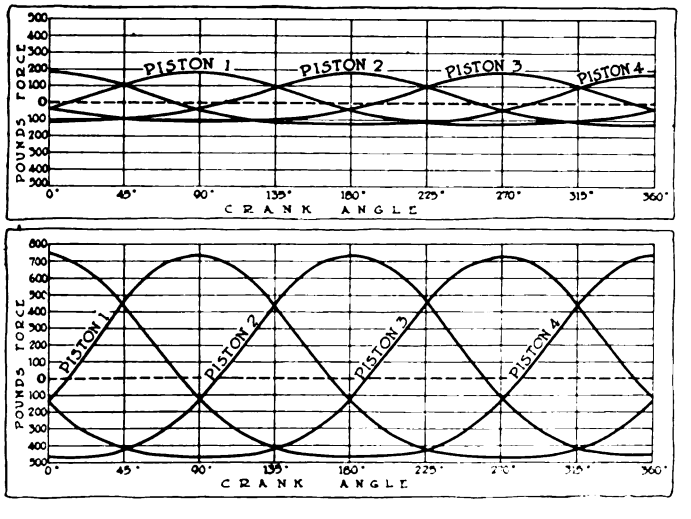
Special Crankshafts

The arrangement of the crankpins is shown in Fig. 14 and Fig. 15 and each exhibits different characteristics. There is not what we could term "looking-glass symmetry" in the same sense that it is found in the conventional shaft with the crankpins at 180 deg. in the same plane. In other words, while the shafts are identical in each half, about an axis in the center, so far as their structure is concerned, one-half, if placed before a mirror, would not show a true reflection of the other half. There will be, therefore, a rocking moment about a plane of symmetry at right angles to the crank axis.

In the first shaft in Fig. 14 a longitudinal couple of large magnitude does exist, due to the centrifugal effect of the crankpins and also the accelerating forces on the pistons. This would tend to rock the shaft about the center 0-0 as shown, and the magnitude is such that it can not be balanced practicably.

In the shaft in Fig. 15, however, while there exists a small rocking moment due to the accelerating forces of the piston masses, and also a rocking moment in a plane at right angles due to the centrifugal effect of the crankpins, the magnitudes of these rocking moments are very small in comparison with those in the first shaft, as can be seen from the sketch. In Fig. 15 the effects of the forces on adjacent crankpins tend to rock the shaft in opposite directions, the resultant being the difference of these moments. In the first case, on the other hand, they augment each other.

Therefore, it is entirely practicable and feasible completely



Figs. 9 and 10—Unbalanced force curves for eight with crankpins at 90 degrees as in motor.

Fig. 8—Upper—at 1000 r.p.m. Lower—at 2000 r.p.m.

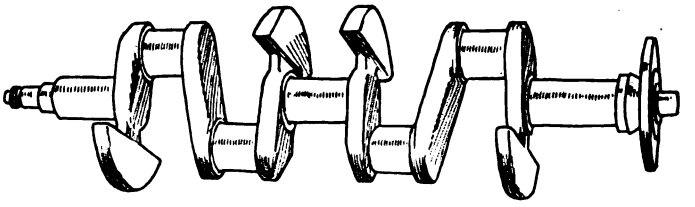


Fig. 13—Ordinary balanced crankshaft

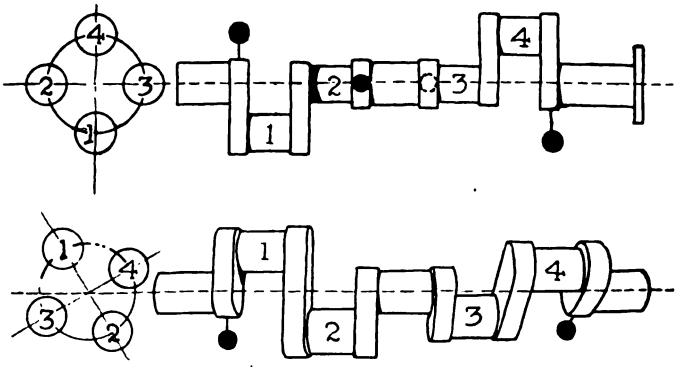

Figs. 14 and 15—Balanced crankshaft with pins at 90 degrees. The lower of the two is the better design

to balance the centrifugal moment by the addition of balance weights on the end crank arms, and also to eliminate the inertia moment to such an extent that its presence would not be observed under any ordinary conditions.

The firing order for the latter shaft would be 1-5, 2-6, 8-3, 7-4 or 1-3, 7-4, 8-5, 2-6 and with crankpins 3 and 4 rotated 180 deg., the firing orders would be 1-5, 2-3, 7-4, 8-6 or 1-4, 8-3, 7-5, 2-6, which, with proper manifold design, are equally as good as the firing order of 1-8, 3-6, 4-5, 2-7, as used in the conventional shaft with the crankpins at 180 deg. The foregoing is sufficient to show the general characteristics of these experimental shafts as we have found them. And our experiments demonstrated that the equality of cylinder performance was of prime importance since we found that, with the unbalanced inertia forces eliminated, we could actually produce vibrations by erratic firing order when different camshafts are used and by purposely creating a condition of unequal cylinder performance.

The general conclusions drawn from these tests are that the theoretically unbalanced forces do not offer such objectionable vibrations as those which may be produced from other sources. This led us to assume that the vibration of the kind arising from the elastic yielding of the parts of the engine are far more serious.

If the vibrations due to the theoretical unbalance of the eight with the conventional crankshaft were perceivable or objectionable to the same extent as the critical vibrations of the six and twin-six, corresponding means could be employed to correct them.

Fig. 12 shows the "Lanchester anti-vibrator," as it can be applied to the eight-cylinder engine, which in effect supplies a countervailing movement of a mass of the same periodicity and opposite in direction to the unbalanced force in the engine. The masses M, revolving in opposite directions, neutralize each other in all but the horizontal plane where the combined centrifugal forces equal the vibratory force in the horizontal plane.

It will be observed that with a greater number of cylinders it would be harder to obtain equality of cylinder performance. Particularly is this true where the individual cylinder displacement is very small, because the little variations which occur either from the differences in valve timing or tappet clearances and manifold designs will have a greater effect than with the same variations on a larger cylinder displacement.

In respect to rigidity the eight is most certainly superior to any other combination. The crankshaft is exceptionally stiff and although the explosive forces in the cylinder of 3½-in. bore exceed those in a 3-in. bore, the great reduction in length and lesser distance between the supports give greater rigidity and consequently less deflection than does a longer shaft even though the pressure imposed upon it be somewhat smaller.

In the eight-cylinder Cole-Northway V-type engine the shaft is 2⅛ in. in diameter and the length between center of supports 10⅝ in.

Periodic vibrations at critical speeds in a six-cylinder engine have been attributed to the synchronism of the torsional oscillations of the crankshaft, due to the impulses and the natural vibration period of the shaft itself.

This was treated in a previous paper before this section, but while it was pointed out that the decreased length of the shaft of the twin-six would be a factor tending to reduce this periodic vibration, it is logical that the critical period in the twin-six will be just as pronounced. By shortening the shaft the periodicity or natural period of the shaft will be higher. But the explosive impulses are also closer together. In other words, the torsional frequency is higher, and since both the natural period and the explosive impulses are higher, the time when the periods will coincide and give a critical vibration will be the same irrespective of the fact that with a light piston and small explosive pressure there will be a decreased twist on the shaft.

If the natural period were of a higher frequency and the torsional period due to impulse had remained as in the six, it is possible that the time of synchronism would not have been within the speed range of the engine. This is precisely the condition that an effort was made to attain in the six by using a big, heavy shaft. Therefore, the same difficulties and disadvantages can be argued against the twin-six as are characteristic of the six, since many of these peculiarities recur in the twin-six. *They are not characteristic, however, of the eight-cylinder engine.*

Minimum Noise

By the term "minimum noise" we mean the ability of the mechanism to *operate* without objectionable sound. Previously we have dealt with the vibration and the noise resulting therefrom, and under this heading we will consider the noise resulting from the parts of the mechanism which come together with metallic contact due to the clearances that must naturally exist.

Since in any engine the clearances are practically the same, the noise therefrom will be substantially the same per contact. *Thus, the multiplication of the parts in operation will increase the noise in the same proportion as such multiplication occurs.*

Let us for a moment consider push-rod clearance. It is necessary in any type of engine to have definite clearances to provide for expansion of the valves. While the weight of the push rods may vary slightly in the case of large and small bore engines, the impact caused by the acceleration of the push rods will be substantially the same and will depend upon the angle through which the camshaft moves in taking up the clearance—in other words, the back-lash angle.

If the minimum specified clearance is not maintained, the noise produced is increased to a marked degree. Under these conditions the total sound made by the conglomeration of the small noises is accentuated in proportion to the multiplicity of parts. These conclusions bring forcibly into prominence the relative merits of the eight and twin-six power plants interpreted in terms of their relative simplicity and proportionate quietness.

Because of the shortness of the cylinder block and the detachable head, which acts as a baffle, and the fact that the connecting passages are proportioned so as to give correct circulation, even temperature throughout the cylinder block is assured.

To the accessibility of the valve mechanism great importance is attached. Given a clear valve alley, as in the case of the eight-cylinder V-type engine in question, it is seen in Fig. 16 that the greater amount of free space with a 90-deg. construction enables more easy manipulation of tools than with the 60-deg. construction of the twin-six. Incidentally, the ease with which the push rods can be moved will be noticed in the cross-section.

In a recent criticism of the eight it was assumed that the accessories must, of necessity, be placed in a so-called conventional position and because the particular construction of the eight did not permit with advantage the placing of the accessories in that position, it was considered distinctly disadvantageous.

It will be observed on the Cole eight, though the position of the accessories is not what is purported to be the conventional one, *distinct advantages are to be gained from the positions in which these accessories are placed.* The position of the water-pump is ideal, for it simplifies to a considerable degree the water-piping in distributing the water to each block.

(*Discussion Appears on pages* 861 *and* 862)

ventional shaft, the existing inertia and accelerating forces are again plotted as shown in curves in Fig. 9 and Fig. 10. The inertia curves being superimposed at crank periods of 90 deg., the resultant is zero, as indicated at 0-0. This is arrived at by subtracting all the negative ordinates, or those beneath the zero line, from the positive ordinates above the zero line.

Figuratively we can arrive at the same conclusion by resolving the forces of inertia and acceleration of each piston into horizontal and vertical components. It will be seen in Fig. 8 that the piston masses 6(1) and 7(1) each have their resultant downward as the piston 6(1), having passed the position of maximum velocity, the energy of the piston will be doing work on the crankshaft while the piston 7(1), not yet having reached the point of maximum velocity, is still being accelerated by the crankshaft, its reaction being, therefore, downward. Adding up the forces we get zero as a resultant, showing that there is positively no resultant unbalanced force.

Special Crankshafts

The arrangement of the crankpins is shown in Fig. 14 and Fig. 15 and each exhibits different characteristics. There is not what we could term "looking-glass symmetry" in the same sense that it is found in the conventional shaft with the crankpins at 180 deg. in the same plane. In other words, while the shafts are identical in each half, about an axis in the center, so far as their structure is concerned, one-half, if placed before a mirror, would not show a true reflection of the other half. There will be, therefore, a rocking moment about a plane of symmetry at right angles to the crank axis.

In the first shaft in Fig. 14 a longitudinal couple of large magnitude does exist, due to the centrifugal effect of the crankpins and also the accelerating forces on the pistons. This would tend to rock the shaft about the center 0-0 as shown, and the magnitude is such that it can not be balanced practicably.

In the shaft in Fig. 15, however, while there exists a small rocking moment due to the accelerating forces of the piston masses, and also a rocking moment in a plane at right angles due to the centrifugal effect of the crankpins, the magnitudes of these rocking moments are very small in comparison with those in the first shaft, as can be seen from the sketch. In Fig. 15 the effects of the forces on adjacent crankpins tend to rock the shaft in opposite directions, the resultant being the difference of these moments. In the first case, on the other hand, they augment each other.

Therefore, it is entirely practicable and feasible completely

The Correct Way to Grind Valves

EDITOR THE AUTOMOBILE:—Often we get into an argument about the correct way to grind valves. Some say turn them all the way around and keep on that way, occasionally putting on some more grinding compound, and others state that you must not turn the valves over one-quarter way around, thus rotating back and forth. Others claim about half way around and thus rotate them backward and forward.

Now, what is the correct way to grind valves?

Plentywood, Mont. J. S. K.

—When grinding valves the valve should not be turned to a complete rotation at any time, but should be worked backward and forward to one-quarter the circumference. After this has been done several times, the valve should be lifted free of the seat and turned a distance of about one-third revolution and then the same reciprocating action carried on.

Fort Warren, Mass. W. N. T.

—The main indication that there is not enough gasoline in the charge is back-firing on quick throttle opening and lack of power on hills.

2—They are called the primary coil and the secondary coil, respectively.

3—Doubtless you are referring to ordinary four-cylinder practice which is to have the cranks at 180 deg. With this arrangement there may be either two, three or five bearings for a four-cylinder motor.

4—Thermo-syphon and pump systems. The thermo-syphon is that in which the water is circulated due to the temperature setting up a flow through the manifolds and radiator. The pump system is that in which the water is positively circulated by pump.

5—Three-point suspension means the suspension of the power plant at three points making a triangular layout. The advantage is that racking of the frame or twisting of the side members has a minimum tendency to impose strains on the motor supports.

6—An open circuit in electricity is a circuit which is not complete and through which current would flow as soon as the gap or opening in the circuit was closed. A closed circuit is one which is complete and through which current is flowing. A divided circuit is one in which the current from the main leads is divided to sub-leads. A grounded circuit is one in which the return current is carried through the construction of the car instead of by wire. It is common practice to ground on the main frame or side member.

7—Irregular and misfiring of the charge.

8—A master vibrator is one which performs the vibrating work for a number of coils. It is used to assure a uniform spark in each cylinder since the same adjustment of the vibrator points is bound to occur for each plug.

9—In order to compensate for the different slopes of the propeller shaft due to spring action.

10—There are universal rims which allow the different types of tire to be used.

11—The timer times the spark by breaking the circuit at the right moment whereas a distributer leads the current to the proper spark plug.

12—The selective type of gearset permits the driver to go into any speed from any other speed without passing through intermediate gears. In the progressive gear it is necessary to go in the order of one, two, three, four or four, three, two, one.

13—A float feed spray carbureter is one in which the gasoline level is controlled by a float and float chamber. All carbureters are designed to be compensating, or in other words, to take care of variations in loads and speeds.

14—The current generated by a dynamo of the type used in automobile practice is direct whereas with a magneto it is alternating.

15—You probably refer to the low-tension make-and-break system in which the make-and-break apparatus was known as an igniter.

16—In a four-cylinder two-cycle motor the crankshaft re-

ceives four impulses per revolution. Since there are 360 deg. to a revolution the explosions will have to be 90 deg. apart and the crank throws arranged accordingly.

17—The high-tension magneto differs from the low tension in that it carries its transformer coil in a unit whereas the low tension has the transformer coil separate. Where magnetos are employed for automobile ignition either the high-tension or low-tension will give perfect satisfaction although the high tension is more compact.

18—The power developed by the engine must necessarily depend on the amount of explosive charge in the cylinder, hence if you open the throttle more there will be more gas in the cylinder and therefore more power. Advancing the spark permits the explosion to take place early in the stroke and by allowing the motor to take advantage of the expansion of the burning gases gives a higher mean effective pressure.

N. Y. License Good in Eastern States

Editor THE AUTOMOBILE:—Will you please let me know the automobile registration requirements for the Eastern States of the United States so far as interchangeability of license is concerned, such as purchasing a New York State license and wanting to take a trip to Birmingham, Ala.? Is it possible to travel through New Jersey, District of Columbia, Maryland, Virginia, North Carolina, South Carolina and Tennessee with a New York license?

Pedro Miguel, C. Z. L. DE LYON, V. V.

—The New York State license will carry you through all the States you mention, provided you do not stay in any longer than 10 days.

Interconnecting Buick Brake and Clutch

Editor THE AUTOMOBILE:—Referring to the model 10 Buick, what is the best way to interconnect the brake and clutch so that the latter will be disengaged before the former is applied?

I would like to make this change and feel that the necessary attachment should be preferably applied to the service brake. No doubt this point has been raised before and you have a ready solution of the problem. Perhaps you know of some device now manufactured for this purpose.

Kindly publish a sectional drawing of the clutch and transmission used in this car.

Hollis, L. I. R. M. DEV.

—In regard to interconnection of brake and clutch on the model 10 Buick this can be accomplished by welding or brazing a large washer on the front end of the rod which connects the high speed lever with the foot control shaft and by inserting a special large-headed pin in the foot brake lever. When the pedal is depressed, this pin will engage with the washer on the high-speed rod thus throwing out the high speed clutch when applying the brakes. At one time, a number of concerns had devices of this nature on the market, but THE AUTOMOBILE has no record of any now for sale. The gearset and clutch assembly for this model is illustrated in Fig. 1.

Information on Owen Magnetic

Editor THE AUTOMOBILE:—In the issue of July 15, page 102, there is a description of the Owen Magnetic drive car. Where, by whom and for what length of time has the Owen Magnetic been made? What is the highest speed?

2—What is the life of the magnetic transmission as compared with the ordinary and friction drive?

3—Could this transmission be put on another car?

4—What does the Owen Magnetic chassis sell for?

Kansas City, Mo. J. W. A.

—The Owen Magnetic cars are made in New York City, by R. M. Owen & Co., and have been on the market for about two years.

2—The magnetic transmission has not been on the market long enough to give any clue as to its ultimate life.

3—This transmission system can be put in another car, but this would be a wasteful operation and would not pay.

4—The price of the Owen Magnetic chassis alone is $3,150. For the complete car the price is $3,750.

M.E.P. Is Mean Effective Pressure

Editor THE AUTOMOBILE:—What is a T-head motor?

2—How can I secure the A. A. A. rules?

3—Is there a company prepared to fit front wheel brakes to a 1916 Chandler?

4—What does M.E.P. mean?

Cambridge, Mass. J. A. J.

—A T-head motor is one in which the exhaust and intake valves are on opposite sides of the cylinder. Two camshafts are generally employed with this arrangement.

2—The contest rules of the A. A. A. can be secured from the American Automobile Association, 437 Fifth Avenue, New York City.

3—THE AUTOMOBILE has no record of any concern prepared to fit front wheel brakes to a 1916 Chandler. This would be a very costly and complicated operation and it is doubtful if it would be possible to secure a practical job.

4—The initials M.E.P. stand for the mean effective pressure. It is secured by dividing the summation of the pressures at all points of the stroke by the length of the stroke.

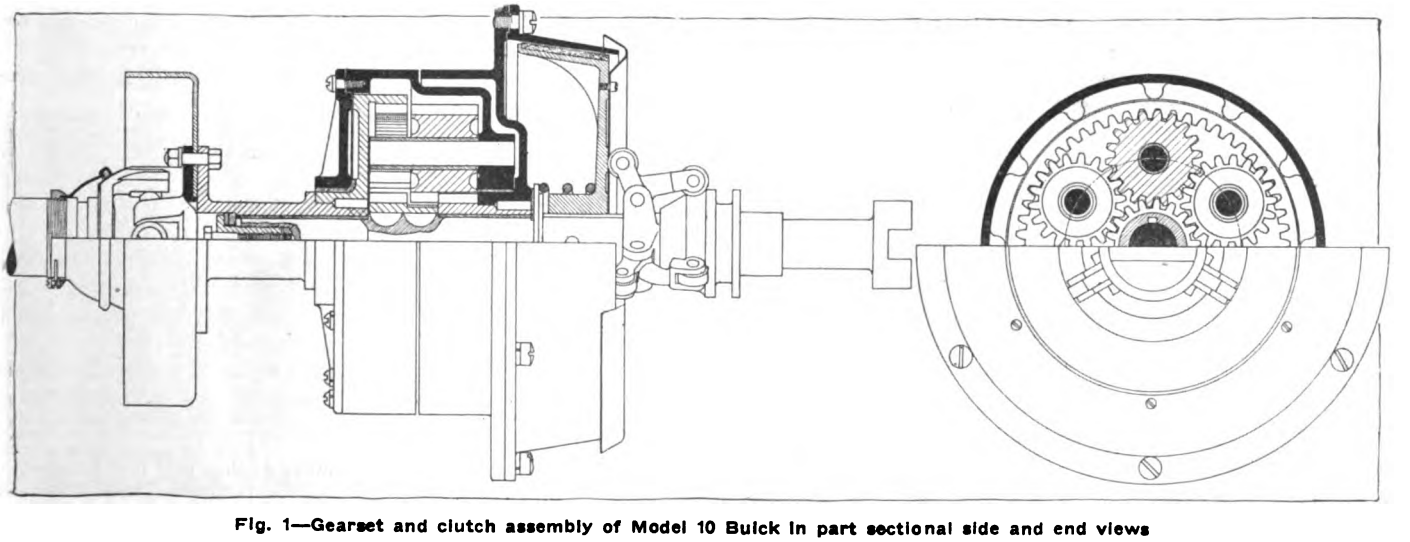

Fig. 1—Gearset and clutch assembly of Model 10 Buick in part sectional side and end views

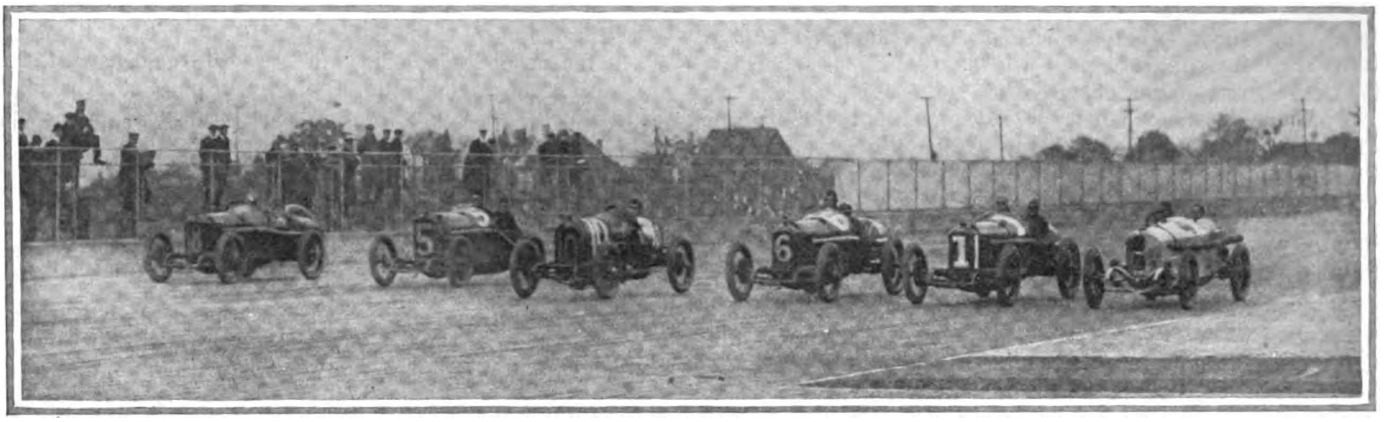


The six cars coming into the stretch for the flying start of the 100-mile race for the Harkness gold challenge cup and $12,000 prizes. Left to right, they are: Mulford, Peugeot; Burman, Peugeot; Rickenbacher, Maxwell; Aitken, Peugeot; Resta, Peugeot; and De Palma Mercedes. As they swept up to the line the thousands of spectators in the stand burst into cheers

Resta Takes Harkness Cup Race at 105.39 M. P. H.

On Sheepshead Bay Track His Peugeot Comes Within 26 Sec. of Breaking 100-Mile World's Record Made at Brooklands

De Palma Wins Match Race with Burman in Two Heats, the First at 111.97 and the Second at 113.86 M. P. H.

Order of Finish in Harkness 100-Mile Gold Cup Race

Car	Driver	Time	M.P.H.
Peugeot	Resta	56:55.71	105.39
Peugeot	Burman	58:38.95	102.43
Maxwell	Rickenbacher	61:00.59	98.33

SHEEPSHEAD BAY SPEEDWAY, Nov. 2—Dario Resta to-day won the final speedway event of the year by winning in his Peugeot from a field of six of the picked drivers of the country in the 100-mile race for the Harkness gold challenge cup, on the 2-mile board speedway here. Besides the laurels of victory Resta, by going the distance in 56 min. 55.7 sec., without having to make a single stop, established a new American record for the century and came within 26 sec. of beating the world's record for the distance made on the Brooklands cement speedway in England some years ago. The Brooklands record is 56:29.93, or only 25.78 sec. faster than Resta's mark of to-day. Resta's average here to-day was 105.39 m.p.h.

Burman Second at 102.43

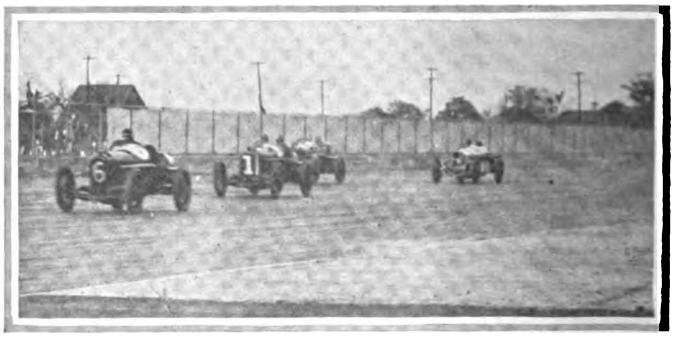
Second place was taken by Robert Burman in another Peugeot, Burman finishing a little over a lap behind the winner, but doing the distance in 58:38.95, an average of 102.43, and beating the mark that Resta made in the 100-mile match race on the Chicago speedway some months ago. Burman had to stop once for a right rear tire which lost him a lap.

Rickenbacher in Third Place

Third place went to Edward Rickenbacher in a Maxwell, who made a non-stop race but whose car was not fast enough for the company. Rickenbacher averaged 98.33 m.p.h., his time being 61:00.59.

Six racers started, the field being made up of four Peugeot cars, one Mercedes and a Maxwell. Resta, Burman, Mulford and Aitken drove Peugeots; De Palma handled the Mercedes and Rickenbacher the Maxwell. Aitken, after leading from the start, was forced out at 12 miles with a broken connecting-rod. De Palma was out at 40 miles, having made two stops for carburetion, his first stop coming at 24 miles. Ralph Mulford, who was the pace setter after Aitken was eliminated, was the hard luck tire driver of the race until at 92 miles when he went out with a broken connecting-rod. Mulford had the fastest car in the race but his speed cost him tires and he stopped regularly at 25-mile intervals to change his right rear. The first change was made in 21 sec. at the end of 28 miles; the second change was at 50 miles; and the third change at 76 miles was made in 23 sec. The fourth time he changed both rears in quick time. Each stop put him back more than a mile, due to time lost in slowing up. In the middle of the race he regained from Resta more than a mile of lost distance but in doing so he brought more tire changes for the right rear, the tire that gave him the most trouble.

While Mulford and Burman were wrestling with tire



The leaders closely bunched at 10 miles as they shot into the grandstand stretch. Left to right, Aitken, Peugeot; Resta, Peugeot; Burman, Peugeot, and De Palma, Mercedes

troubles Resta was going along at an amazingly steady pace of a little over 105 m.p.h., which he set from the start and did not vary at any one of the 10-mile points.

The start was a flying one with De Palma in the favored position at the pole and with the order outside of him Resta, Aitken, Rickenbacher, Burman and Mulford. In the first lap De Palma put his Mercedes in the lead in the first turn but Aitken took the lead in the backstretch and when they crossed the tape at the end of the initial lap the order was Aitken, Mulford, Resta, De Palma and Burman, with Rickenbacher trailing. Aitken at once established himself in the lead with Resta and De Palma close up, which order continued until 12 miles when Aitken was out and at this point Mulford had passed Resta and took the leadership, with Resta, Burman and De Palma all bunched 100 yd. back of him. Soon, Mulford had 200 yd. on this trio and a few laps later Mulford was more than the length of the homestretch in the lead. Mulford was making lap after lap at 108 m.p.h., when his first tire went and he was placed back nearly a lap, giving the leadership to Resta at 28 miles. Mulford's average at 20 miles was 105.18 m.p.h.

Tires the Determining Factors

With Resta slightly in the lead at this point due to Burman, Mulford and De Palma all stopping between 24 and 28 miles, the tense interest of the race ended and everybody sat back waiting for tires to become the deciding factors, as they did. Good judgment and fortune favored Resta as they did in the Chicago 100-mile event and he was an easy winner, finishing more than a lap ahead of Burman.

At the end of the first 10 miles Aitken's Peugeot led, having averaged 102.62 m.p.h. When 20 miles had been covered Mulford was ahead with a speed of 105.18. At 30 miles Resta had worked his way to the front, his average standing at 105.36. He held this position during the remainder of the race, his average speed in m.p.h. at each 10 miles being as follows: 40 miles, 105.88; 50 miles, 105.57; 60 miles, 105.31; 70 miles, 105.39; 80 miles, 105.53; 90 miles, 105.57; and 100 miles, 105.39.

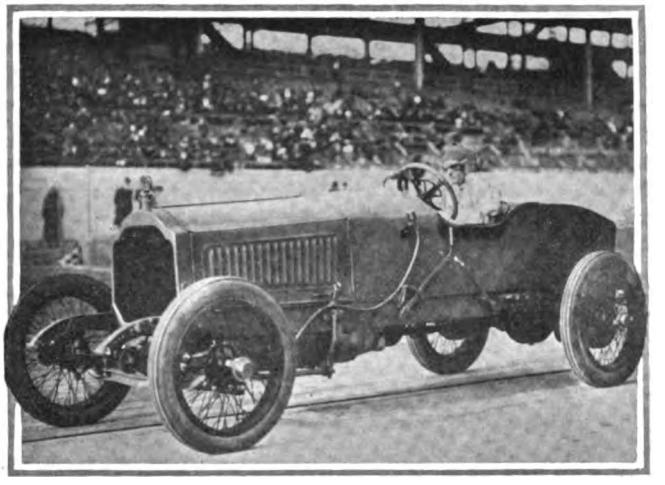
De Palma and Burman in Match Race

In addition to the 100-mile race there were two heats of 4 and 6 miles, respectively, between De Palma in the twelve-cylinder Sunbeam, which the Packard company purchased some months ago and Burman in the Blitzen Benz. These races were the most exciting of the afternoon, the finishes being so close that one car was alongside of the other. De Palma won both, taking the 4-mile heat in 2:08.61, an average of 111.97; and taking the 6-mile heat in 3:09.65, an average of 113.86 m.p.h. In these heats the cars were rarely more than a few lengths apart. On the turns De Palma, with the pole position, ran low, while Burman rode high, losing a length or so but coming into the stretches at terrific speed and going alongside and in a few instances passing De Palma, only to drop back a little on the turn. At the finish the front wheel of the Benz was alongside the rear wheel of the Sunbeam. The Sunbeam has cylinders 80 by 150 mm., giving a piston displacement of 549 cu. in. The car weighs 2800 lb., has 120-in. wheelbase and used 32 by 4½ tires. The cylinders are cast in groups of threes and arranged in conventional V groups.

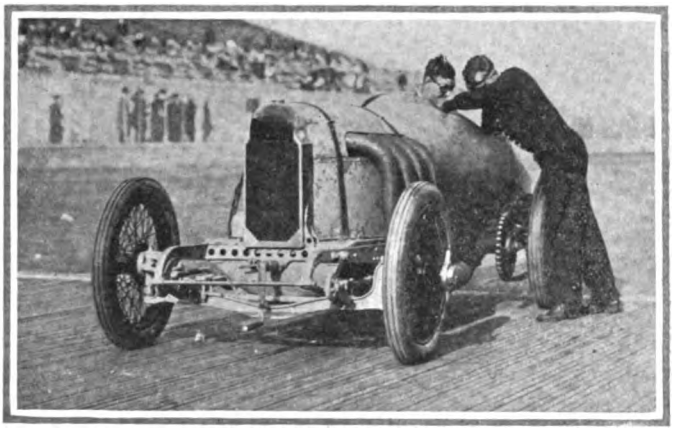
Burman's 2-Mile Trial

A third feature of the afternoon was a 2-mile exhibition by Burman in the Benz in which he was unofficially clocked at a speed of 116 m.p.h., which, if official, would establish a new American record for that distance.

Jesse G. Vincent, chief engineer and vice-president of the Packard company, drove a Packard twin-six with racing body a 2-mile lap in 1:10.52, a speed of 102.25 m.p.h. The car was standard except the timing was changed for higher speed; pistons were arched on top to give higher compression; a double Zenith carbureter was used and the rear axle gear ratio was to give 34 m.p.h. at a crankshaft speed of 900 r.p.m. Mr. Vincent says the crankshaft speed was 3000 r.p.m. on the backstretch.



The Packard twin six which J. G. Vincent, vice-president of engineering of the Packard company, drove around the 2-mile Sheepshead Bay speedway in 1:10.52, or at the rate of 102.25 m.p.h. This is a stock car except for the racing body and that the timing was changed for high speed work, the pistons were arched on top to give higher compression, a double Zenith carbureter was used and the rear axle was geared to give 34 m.p.h. at a crankshaft speed of 900 r.p.m.



Burman giving his Blitzen Benz a few preparatory touches just before the start of the match race with Ralph De Palma in the twelve-cylinder Sunbeam. De Palma won the first heat of 4 miles, two laps of the track, in 2:08.61, or at 111.97 m.p.h., and the second heat of three laps, 6 miles, in 3:09.65, or at the rate of 113.86 m.p.h.

In the 100-mile event Zenith carbureters were used on all six cars, as were Bosch magnetos and Silvertown cord tires. Wire wheels were used on all cars.

In the way of lubrication, Resta, Burman, Rickenbacher, Mulford and Aitken used Oilzum and De Palma used Monogram. Boyce Motometers were used by all the cars in the 100-mile race.

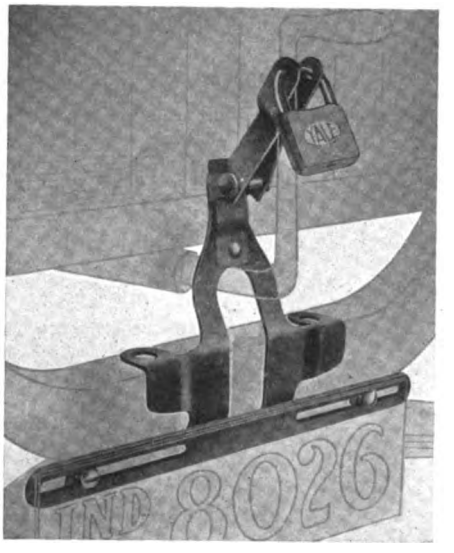
The piston displacement of the Peugeots driven by Resta, Mulford and Aitken is 274 cu. in., and that of Burman 296. The Maxwell is 298. The Blitzen Benz has four cylinders 7 5/16 by 8 in., and is one of the biggest racing motors of the day. The car weighs 2800 lb., is chain driven, uses a Benz carbureter, two Bosch magnetos, and carries 33 by 4 and 33 by 5 tires, front and rear. It is geared 1 to 1 between the motor and the rear axle.

The day was very windy and rather cold, increasingly so as the shadows began to lengthen toward the close of the 100-mile race but in spite of these conditions a crowd of over 25,000 thronged the stands and hundreds of cars were parked within the inclosure.

ACCESSORIES

Oakes Kranklock for Fords

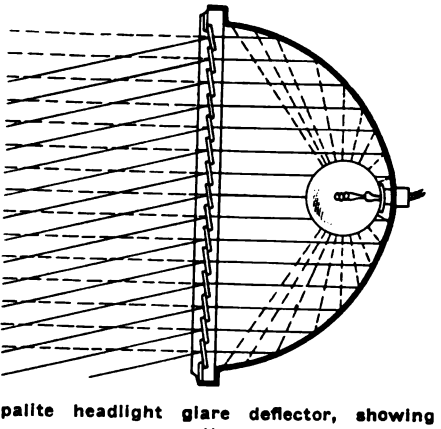
THE Kranklock is a combination starting crankholder and license plate bracket designed to fit on the center bolts of the Ford front spring, making its attachment simple and rigid. Its advantages are that it holds the starting crank upright and rigid as shown in the accompanying illustration, that it can be locked, thus making the car theft-proof and also that it holds the license number securely in a correct position.—The Oakes Co., Indianapolis, Ind.



Oakes Kranklock for Fords, illustrating mounting

Opalite Glare Deflector

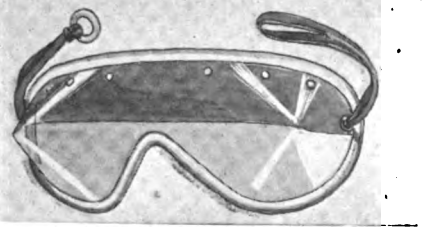
This device consists of a series of Parolin prisms which run diagonally across the headlight lens, each prism overlapping the top of the one below it, the prisms being arranged at such an angle that proper deflection and diffusion of the light rays result, thus overcoming all blinding glare. The manufacturers state that the device will not break, even if the headlight glass is shattered and emphasize that it kills the glare from the lamp but not the light, simply softening the beams without impairing the illumination of the road. Opalite is made to fit all makes of lamps, is permanent and positive in action and is adjusted in a few moments.—Price $2 per pair.—M. & K. Auto Sundries Co., New York City.



Opalite headlight glare deflector, showing action

Micalite Fireproof Celluloid

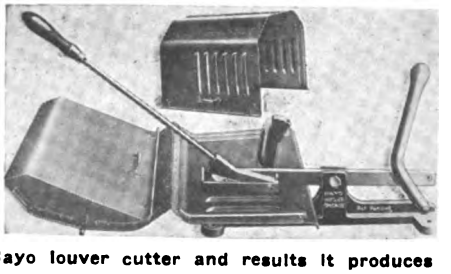
A fireproof celluloid under the trade name of Micalite has been placed upon the market and is being manufactured in transparent sheets which are being used in the Micalite eye shield. Another interesting feature of the material is that although it has been generally understood that such a material as Micalite could not be stained it is being produced in colors suitable for use in goggles, namely, amber in a light shade or amber in two shades in one piece. This development has made possible the all-one Micalite eye shield which is now regularly marketed. The darker part is intended for the brightest lights and the lighter part for ordinary use.—Strauss & Buegeleisen, New York City.



Micalite eye shield of fireproof celluloid

Mayo Louver Cutter

A device for cutting louvers or ventilating openings in the bonnets of cars has been put out under the name of the Mayo louver cutting machine. It is intended for garage men who can solicit the work of cutting these louvres in the hoods of cars in their vicinity. The machine which is shown in the accompanying illustration is strongly constructed with hardened tool-steel cutters for left and right sides of the hood. The cutters can be removed and sharpened. The complete machine weighs 45 lb. and the dealers' price is $30 net.—Mayo Mfg. Co., Chicago, Ill.



Mayo louver cutter and results it produces

Arguto Wood Bushings

These oilless bushings are designed for shop work where oiling is objectionable or difficult, the wood being chemically treated so that lubrication is unnecessary, making it especially well adapted to loose pulley work, where centrifugal force throws oil out of the ordinary bearing. Arguto bushings are not recommended for heavy line shafting, because wood is not strong enough to withstand the stresses but for countershafts, light line shafting and similar work the wood gives excellent results, the makers citing instances where these bushings have been in satisfactory use for periods up to nine years. When using the Arguto bushings the shaft is lightly smeared with a lubricant, largely as a rust preventive in case the shaft is not immediately operated. For loose pulleys on grinding machinery these bushings have the advantage that they run perfectly dry and cannot gather abrasive dust. The coefficient of friction is about the same as that of ordinary metal line shaft bearings.

Cylindrical bushings are furnished from ¼-in. bore 1 in. long to 3-in. bore 16 in. long, the smallest size listing at 5 cents each and the largest at $4.50.—Arguto Oilless Bearing Co., Philadelphia, Pa.

Holdfast Nut

Holdfast nuts are made by a chemical welding process, the threads of standard size nuts being coated with a soft friction metal which grips the threads of the bolt and holds them tightly. A special tap is used to remove part of the soft metal from the bearing or load surface of the thread after the soft metal coating has been applied, leaving the metal on the clearance side. The nuts are applied in the ordinary way and can be used several times before wearing out the soft metal coating. Any size, style or grade can be furnished.—Holdfast Nut Co., Chicago, Ill.

Beamish Lunch Bag

The Beamish bag for cold lunch is of strong paper stock, the lower part being of heavy manila tag stock, the entire bag being paraffined to make it waterproof. The makers state that it will keep cold lunches clean and moist for a long time and that bottles packed in the bag with ice will keep cold for twelve hours. Each bag may be used several times. Price 10 cents each.—Beamish Glass Co., Kansas City, Mo.

Cylinders Once More

IN automobile development it seems fated that there should always be cylinder factions. We began with one versus two, had an interval of two or three and then a long session of two or four. Then came a general acceptance of four, followed by more argument with the coming of the six. It was soon seen that both four and six had their legitimate spheres and the argument died away. Now, in one short year, we have both the eight and twelve providing a new three-cornered problem with the six for the other side of the triangle.

It is devoutly to be hoped that we shall not see engineers split up into groups over this new phase, because such grouping injures progress. The proper state for an engineer is that of the open mind; to assume the newest thing is good until it is proved instead of expecting failure until disproved. There is a great big difference between these two ways of looking at a thing, and one stands for progress while the other does not.

Marvelous Motor Progress

THAT 1915 has seen a more rapid development of the gasoline engine than any previous period of three times the length is undeniable. The high efficiency engine has been known for several years, though exploited but little in America; the eight and twelve-cylinder motors were practically not known anywhere. Now, in a single year our engineers have accepted and adopted high efficiency design and added to it the novel types of motor. Most remarkable of all, perhaps, is the fact that everyone from manufacturer to user is satisfied with the success of the engineers' work.

Not long ago engineering progress was undoubtedly retarded by the notion that rapid engineering development was uncommercial. The results of this year's business shows rather that engineering advance is one of the greatest assets of the industry. The automobile of 1916 is a far better car than the machine of two years ago, it is selling in far larger quantities, it is costing less to run and it is attracting more and more of the population to become automobile owners. Thus the first time for many years that the engineers have been given a free hand they have shown how great the part they play in stimulating sales directly.

Racing Car Making

THE recent editorial in THE AUTOMOBILE, Wanted! Racing Cars, has stimulated a good deal of correspondence which goes to show that the problem of supplying good cars to fill our speedways next year is being considered in many quarters. The general idea seems to be that the popularity of racing may create more small firms who will specialize solely on racing chassis and cater solely to the speedways, but the point first requiring to be settled is whether a sufficiently reliable market is assured.

There is obviously a very widespread feeling that the prize money needs to be distributed so that car builder and driver are no longer dependent upon winning or coming close to winning if they are to see any return for their work. The stars may draw their tens of thousands, but the chorus is also deserving of its hire.

With this view it is impossible to dissent, however hard it may be to devise a means for readjustment that will please everyone, and it is now the turn of the speedway organizations to offer a suggestion. Why not appoint a joint committee of the A. A. A., manufacturers, speedways, entrants and drivers and get something settled before the dawn of 1916?

Automobile Reserve Corps

THE ostensible purpose of the establishment of an Automobile Reserve Corps in this country is to provide a volunteer transport service, trained and ready at a moment's notice to mobilize or concentrate our small army. This should make our fighting force marvelously mobile, for we have many more automobiles available than all Europe could claim at the opening of the great war. Incidentally this Automobile Reserve Corps, with each recruit a unit in an active national patriotic organization, should raise the standards of citizenship. There are many motorists who do not feel competent to shoulder a gun. They feel no sense of duty other than at the polls.

Chandler Stock Now $10,000,000

New Régime To Increase Yearly Car Output from 9000 to 20,000

NEW YORK CITY, Nov. 1—A new régime in the Chandler Motor Car Co., Cleveland, Ohio, has been started by an increase in the stock of the company from $425,000 to $10,000,000, this increase being all common stock which is being put on the market by Hornblower & Weeks, 42 Broadway. This additional common stock is not all being sold, $3,000,000 being held for future sales. It is understood that Hornblower & Weeks have sold all the remainder already at 85. The stock will soon be listed on the exchange.

By this new financing scheme the capacity of the Chandler factory it is expected will be increased to 20,000 cars to be built in the next twelve months. There were 9000 cars built during the last year. Under the new financing the control and management of the company will remain with the old stockholders, and the majority of the board will be made up of the old Chandler organization, including F. C. Chandler, president; C. A. Emise, vice-president; W. S. Mead, vice-president; and Samuel Rogers, treasurer. The proceeds of the sale of new common stock will be used for increasing the factory capacity. During the last four months one factory addition has been under construction and is now nearing completion which will double the capacity of the factory.

Since its inception the rise of the Chandler factory has been one of the spectacular developments of the automobile industry, particularly in that field where price has been in the zone between $1,200 and $1,700. The Chandler six was announced in February, 1913, at the Chicago show. The feature of its announcement being the first six-cylinder car to be marketed in quantities at a price of $1,750. Two years later at the Chicago show, 1915, the motor car field was further electrified when the price was reduced to $1,295 which set a new low figure for a car of its class.

During the past year the stockholders of the Chandler company have received 100 per cent cash dividend on their common stock and the regular 7 per cent dividend on the preferred.

—

Maxwell to Aid Dealers' Finances

DETROIT, MICH., Nov. 1—*Special Telegram*—The Maxwell Motor Co. has decided to use part of its surplus by making deposits in banks in different parts of the country where Maxwell dealers are located and enable the latter to get loans from the banks in order to be able to pay cash for cars ordered in December, January and February, during which months sales are almost always at a minimum. The arrangement between the banks and the Maxwell company is to be with the understanding that the dealer will be given credit equal to the company's deposit, the interest to be not more than 6 per cent. The dealer is to put up from his own resources about one-fourth of the purchase price while the balance will be made up from the loan, thus enabling cash payment on delivery of the cars. Certificates of deposit bearing 3 per cent interest will be accepted by the Maxwell company, the deposits being made for six months. The certificates will also be negotiable by special arrangement between the company and its banks. The dealers' notes will be collected by his bank.

—

Studebaker To Retire All Serial Notes—$2,300,000

DETROIT, MICH., Oct. 30—The Studebaker Corp. has decided to retire all of its outstanding serial notes, amounting to $2,300,000, although the last of them are not due until 1922. For this purpose the 20,684 shares of common stock held in the corporation's treasury, will be offered to common stockholders of record at the close of business Nov. 20, at $110 a share, on the basis of 7 per cent of their holdings. In other words if a stockholder has 1000 shares of common on Nov. 20, he can buy seventy shares of the stock now in the treasury at $110 a share.

After the retirement of these notes the Studebaker Corp. will have no debts excepting current accounts and its working capital will be $22,050,000 of which $6,500,000 is cash. It is expected that the special surplus account used for amortization of preferred stock will soon total $2,500,000 which will then make it possible to declare more than 6 per cent dividends. The corporation's charter provides that only after the surplus has reached that amount can a dividend in excess of 6 per cent be paid.

—

Safford McQuay-Norris V. P.

ST. LOUIS, MO., Nov. 1—L. A. Safford, formerly Chicago manager of the Chilton Co., publishers, of Philadelphia, Pa. has been made second vice-president of the McQuay-Norris Manufacturing Co. of St. Louis.

Cotton F. W. D. Advertising Manager

CLINTONVILLE, WIS., Oct. 29—J. D. Cotton has been appointed advertising manager of the Four Wheel Drive Co., Clintonville, Wis., and has already taken up the duties of the advertising and promotion department.

H. W. Ford Controls Saxon Co.

Buys Hugh Chalmers' Stock—$500,000 Involved—To Build 28,600 Cars

DETROIT, MICH., Oct. 30—Harry W. Ford, president of the Saxon Motor Co. has purchased all the stock which Hugh Chalmers, president of the Chalmers Motor Co. held in the Saxon company. The deal involves a cash transaction of half a million dollars and makes Mr. Ford the largest individual stockholder in the Saxon company, of which the original stockholders were, besides Mr. Chalmers and Mr. Ford, Lee Counselman, Percy Owen, Geo. W. Dunham, H. H. Pinney, C. A. Pfeffer, C. A. Woodruff and C. C. Hinckley, the latter four having disposed of their interests some time ago. The manufacturing schedule of the Saxon company for the present season calls for a production of 28,600 cars.

Harry W. Ford came to the Saxon company through Mr. Hugh Chalmers. He worked in the advertising department of the National Cash Register Co., Dayton, Ohio, while Mr. Chalmers was general manager of the company. When the latter organized the Chalmers Motor Co. he asked Mr. Ford to join him and put him in charge of the advertising department of the new company. When the Saxon Motor Co. was organized by Mr. Chalmers and other Chalmer's officials they chose Mr. Ford as president of the new concern.

—

Overland Sales 100% over Oct., 1914

TOLEDO, OHIO, Oct. 28—President J. N. Willys in a statement at the annual meeting of the Willys-Overland on Oct. 26, stated:

"August and September shipments increased 400 per cent over the same months of a year ago. October sales increased 100 per cent over October a year ago. New buildings are now practically completed which will permit an increase in output to 1000 cars a day by March 1, which, from present indications, will be fully required to produce new models planned for 1916. The Willys-Knight deliveries are 40 per cent greater than we had planned."

—

Alter Price Remains Unchanged

PLYMOUTH, OHIO, Oct. 28—The Alter Motor Car Co. has brought out its 1916 model with few changes. The price of the car is $685, the same as last year. This includes starter, one-man top, electric lighting, horn, etc. The wheelbase has been lengthened to 108 in. and 32 by 3½ in. demountable rims are added.

Sept. Exports Are $10,711,133

Over $1,000,000 Better Than Aug.—Trucks Total 2227 and Cars 4299

	September, 1914		September, 1915	
	No.	Value	No.	Value
Cars ..	646	$597,904	4,299	$3,215,459
Trucks..	128	294.288	2,227	5,882,255
Parts ..	...	34,618	...	1,613,419
Total. ...		$926,910	...	$10,711,133

WASHINGTON, D. C., Oct. 31—Exports of automobiles, trucks and parts during September, 1915, showed a value of $10,711,133. This is quite an increase over the previous month's figures, which were $9,567,348 and over September, 1914, with only $926,910.

Trucks, numbering 2227 and valued at $5,882,255 and cars, numbering 4299 and valued at $3,215,459 with $1,613,419 in parts, were exported.

Both cars and trucks increased in number over August. One interesting point brought out in the above table is that though the number of cars shipped in September increased 460, the value only increased $93,265, showing the September shipment included cheaper-priced cars than those shipped in August. The number of trucks increased 613 and the value $1,495,062.

There was a drop in parts shipments, which amounted to $1,613,419 as compared with $2,038,321 in August.

Firestone and Miller Tire Companies Plan Additions

AKRON, OHIO, Oct. 30—The Firestone Tire & Rubber Co. and the Miller Rubber Co. will soon add to their plant outputs with new buildings. The new Firestone plant will be erected on the east side of Main Street, opposite the present plant. The Miller company is planning a new factory, the permit for which will be issued in a few days. This new building is the third to be started within the past six months.

A permit for the erection of the Firestone clubhouse has been issued. The new building will cost $85,000.

Paige Sales for October Show 600 Per Cent Increase

DETROIT, MICH., Oct. 31—During the first fifteen days of October, or thirteen actual working days, more Paige cars were shipped than in any other period in the history of the Paige-Detroit Motor Car Co. October sales show an increase of 600 per cent over October of last year.

500 Men Rush New National Plant to Completion

INDIANAPOLIS, IND., Oct. 30—More than 500 men are working overtime in order to complete the new plant of the National Motor Vehicle Co. Operations in the new building are expected to commence in about sixty days. The company is spending about $100,000 to enlarge its plant, and the new buildings are two stories high and 678 ft. in length. This means that the length of the additions is approximately two city blocks.

Chevrolet Cars To Be Assembled in McLaughlin Plant

FLINT, MICH., Oct. 30—The Mc-Laughlin Carriage Works, Oshawa, Canada, have completed an arrangement with the Chevrolet Motor Co. of Delaware, whereby their big carriage plant in Oshawa will be turned into an assembling plant for Chevrolet cars. At the same time the McLaughlin concern takes charge of the Chevrolet Motor Co. of Canada, recently formed to operate a plant in West Toronto. Thus the Crevrolet business in Canada will be controlled entirely by the McLaughlins.

Through the new arrangement it will now be possible to increase the production of Chevrolet cars in Canada from 5000 to 12,000 for the season of 1916. An output of 20,000 has been planned for 1917, it is said.

The McLaughlins have a controlling interest in the McLaughlin Motor Car Co., Ltd., which assembles and sells the Canadian Buick, the General Motors Co. having the balance of the stock.

King Has Improved Model

DETROIT, MICH., Nov. 1—The King Motor Car Co. has announced an improved model five-passenger, eight-cylinder King at $1,150, f. o. b. Detroit, $200 less than the King eight brought out a year ago.

The new car has a larger motor, 2⅞ in. by 5-in. stroke. Other modifications include a larger carbureter, refinements in lubrication, radiation and ignition. The main points in the design are unchanged. Color has been changed from blue to a salon green body and hood, with black fenders, running gear and wheels; with a fine gold stripe.

Kelly and Springer Return

NEW YORK CITY, Oct. 28—John H. Kelly, sales manager of the Republic Rubber Co., Youngstown, Ohio, accompanied by Frank V. Springer, export manager, returned on the Adriatic to-day from a two months' trip in Europe.

Porter Rubber Plant in Salem

SALEM, OHIO, Oct. 30—The Porter Rubber Co. has been organized with a capital of $125,000, and will erect a plant in Salem. The officers elected are as follows: President, J. C. Porter; vice-president, T. H. Boyd; treasurer, E. E. Boyd.

Peerless and General Veh. Co. Sold

New Corp. To Take Over Both —Trucks and Motors To Be Made

NEW YORK CITY, Nov. 3—The Peerless Truck & Motor Corp. has been formed in this city to-day to acquire the Peerless Motor Car Co., Cleveland, Ohio, and the General Vehicle Co., Long Island City. Nothing definite as to the capitalization or plans of the new corporation is at present known but it is understood the manufacture of commercial vehicles will be continued and that the manufacture of passenger cars at the Peerless factory is assured as an eight-cylinder car will be brought out in the near future. The General Vehicle Co., through its agreements with the Mercedes company in Germany has control of certain aviation features which it is expected will be developed and vigorously pushed in this country.

The exact personnel of the Peerless Truck & Motor Corp. is not known, but it is expected that it is closely allied with the electrical interests which secured control of the Peerless company over 3 years ago.

Gasoline Shortage in Paris Threatens to Stop Taxicabs

PARIS, Oct. 23—The shortage and high price of gasoline in Paris has become so serious that the taxicab service is threatened with a stoppage. The municipal authorities have taken the matter up, but have not yet arrived at any decision other than a statement that drivers are not allowed to change their rate of fares without giving official notice and changing the color of the taximeter flag to correspond with the scale they are using.

It was generally reported that the high cost of gasoline was due to the large requisitions made by the military authorities, but according to an official statement no extra requisitions have been made. This statement is not generally believed. One of the explanations given by the refiners is that they are unable to get the tank boats which normally bring gasoline up the Seine to Paris. The Roumanian and Russian supply of gasoline has been cut off, but this only represented 20 per cent of the whole, the remaining 80 per cent coming from America. It is known that there is no shortage of gasoline for military purposes; in certain cases soldiers report they are so well supplied they can wash their clothes in gas. As gasoline has now become a first necessity, all civilian users are asking if it is not possible to give them greater consideration without hampering the military.

Canadian Ford Profits $3,202,458.15

Annual Statement Shows Gain of $1,179,962.09 Over 1914 —Cash $2,609,997.65

FORD, ONT., Oct. 26—The annual financial statement of the Ford Motor Co. of Canada, Ltd., shows that during the fiscal year ending Sept. 30, 1915, the company made a net profit of $3,202,458.15 or an increase of $1,179,962.09 over the profit of 1914.

The assets totaled $9,182,408.30 as compared with $5,603,618.41 in 1914, an increase of $3,578,789.89 for the year just ended. Among the items enumerated the one showing the biggest increase is that of cash on hand or in the banks, which totaled $2,609,997.65 or nearly $1,400,000 more than in 1914. An increase of nearly $1,000,000 is also shown for the home plant's value, which is given at $2,743,112.07 as against $1,875,114.36 in 1914. For branch plants there is shown an increase of over 100 per cent. Accounts receivable which were marked down for $347,149.17 in the 1914 report now show a total of over $1,000,000 of which over half represents foreign accounts.

Among the liabilities all the items with the exception of one show big increases, this one exception being the dealers' contract deposits with which is also included miscellaneous credits. The total is $115,884.68 or about $1,000 less than the previous year.

Charges Fraud in Fender Test

CHICAGO, ILL., Nov. 2—Suggestions of bribery and fraud in the conduct of fender tests for the city of Chicago may result in throwing considerable light on the conduct of the so-called tests of safety fenders, which have been going on in Chicago. H. L. Eisenhauer, president of the Telescopic Fender Co., made charges before the judiciary committee of the city council yesterday, which involved Emanuel Freidlander, president of the Fender Manufacturers' Association. It is expected that these will result in an airing of the conditions in the fender tests, as information, it is understood, is to be placed in the hands of the State attorney.

Eisenhauer's attorney paved the way for the disclosures by making insinuations regarding the good faith of the committee which has been testing truck fenders under the direction of the deputy superintendent of police. The tests were made for the purpose of recommending to Chief Healey, which fender should be approved by the police department, as complying with the fender ordinance passed nearly a year ago. Eisenhauer said he paid $300 to Freidlander, the first $100 of which was to be paid over to the city to meet the cost of the test. In accordance with Freidlander's statement all the business is being done between the fender association and the testing committee. Eisenhauer said that Freidlander gave him a receipt and a written guarantee that he would get a certificate of approval of the fender or receive his money back. The second $100, according to Eisenhauer, was to assure the passage of the fender, and the third $100 was paid on the representation that the association needed the money and that "everything was fixed."

It seems that the telescopic fender has not been approved as yet, hence the disclosures. The deputy superintendent of police, in charge of the tests, claims that the Eisenhauer payment of the second $200 was for the purpose of bribing one of the committee but it was unsuccessful. The Standard Fender Co., a member of the association, is the only concern thus far which has received the approval of the committee. The chief of police, however, has not issued a certificate to the Standard company and the latter is complaining because the certificate is held up. The Standard Fender Co. is represented by attorney Frank L. Childs, who, by the way, is the attorney for the Chicago Motor Club. The chief of police has withheld the issuance of the certificate to avoid creating anything like a monopoly.

Ford Motor Co. of Canada, Ltd., Balance Sheet for Fiscal Year Ending Sept. 30, 1915

	1915	1914

Total	$9,182,408.30	$5,603,618.41

$3,000,000 Co. to Build Lozier

Property Bought by Assoc'd. Lozier Purchasers—New Interests Elect Officers

DETROIT, MICH., Oct. 29—With a capital stock of not less than $3,000,000 the Lozier Motor Co. will be re-organized and will continue to make Lozier cars as a going concern.

Two of the big stockholders, Maurice Rothschild and Charles Shongood, who were vice-presidents of the company, and who were among those who purchased the assets of the old concern, have withdrawn from the company and disposed of all their holdings to Theodore Friedeberg, Harry and Samuel Frank, who now control all the stock of the company.

The reason of the withdrawal of Mr. Rothschild is due to the fact that he is affiliated with the Harris Bros. Co., Chicago, which firm is commonly known as the Chicago Housewrecking Co. It caused people to believe that these firms were actually interested in the Lozier company and intended only to continue the business for liquidation purposes, which has not been the intention of the purchasers of the old concern.

As evidence that the business is to be continued, a deal was completed a few days ago between the present stockholders and the Detroit Trust Co., trustee in bankruptcy for the former bankrupt concern, whereby the real estate and plant here in Detroit, upon which the Associated Lozier Purchasers had an option, has been purchased by the latter, after the proposition had been submitted to the United States district court and approved by it.

The officials of the Lozier Motor Co. are, Theodore Friedeberg, president; Harry Frank, treasurer and Samuel Frank, secretary and general manager. U. G. Thomas is factory manager.

Steel Horse Farm Tractors

MILWAUKEE, WIS., Nov. 1—The Steel Horse Co. of Milwaukee plans to manufacture a general utility gas tractor. The company is capitalized for $25,000 and is backed by William B. Reith, Walter D. Mann and Adolph C. Graf. The tractor is designed especially for farm use and will haul a plow, cultivator, seeder, harrow or other light farm implements and can be used for light haulage of other kinds.

Ainsworth Mfg. Co. Organized

DETROIT, MICH., Oct. 30—The Ainsworth Mfg. Co. has been incorporated with a capital of $100,000 for the pur-

pose of manufacturing automobile accessories such as windshields, etc. The principal organizer of the company is Harrison Ainsworth, for many years with the Rands Mfg. Co. and with the Rover Motor Co., Coventry, England. He will be secretary-treasurer while Clarence H. Booth, formerly general manager of the Studebaker Corp., is the president. Others interested in the concerns are: George W. Golden, of Golden, Belknap & Swartz; L. D. Bolton, Detroit representative for the Brown-Lipe Co.; Alonzo P. Ewing, of the Detroit City Gas Co.; R. J. Purdy, mechanical engineer. For the present the plant will locate at Franklin and Dubois Streets, occupying 25,000 sq. ft. of floorspace in the old Ideal Mfg. Co. plant.

—

Regulate Bay State Headlights

BOSTON, MASS., Nov. 1—Regulations for automobile headlights have been formulated by Massachusetts Highway Commission, making them effective Jan. 1, 1916. The regulation reads as follows:

Wherever there is not sufficient light, within the limits of the highway location, to make all vehicles, persons, or substantial objects clearly visible within said limits for a distance of at least 150 ft., the white lights which a motor vehicle is required to display by Section 7 of Chapter 534 of the Acts of 1909 shall, when said vehicle is in motion, throw sufficient light ahead to show any person, vehicle, or substantial object upon the roadway straight ahead of the motor vehicle for a distance of at least 150 ft. Any light thrown directly ahead or sidewise shall be so arranged that no dazzling rays from it or from any reflector shall be at any time more than 3½ ft. above the ground on a level road at a distance of 50 ft. or more ahead of said vehicle, and said light shall be sufficient to enable the operator of the motor vehicle to see any person, vehicle, or substantial object upon the roadway or side thereof, for 10 ft. on each side of the motor vehicle 10 ft. ahead of said vehicle.

The commission took the stand that a State regulation would prevent any cities or towns making rules that would puzzle automobilists. It also planned to word the regulations so that it would not be necessary to adopt any device unless the owner of a car wanted to do so.

—

Annual Registration for D. C.?

WASHINGTON, D. C., Oct. 30—If the recommendations of Ben L. Price, tax collector, are adopted by Congress, Washington motorists will have to pay an annual registration fee instead of the perpetual license fee of $2 that is now exacted. In his annual report Price recommends that a license fee based on horsepower rating be charged and he suggests that the fees exacted by Maryland or Virginia be followed. If such a fee is charged it will take the place of the present personal tax fee that is charged in addition to a fee of $2 that must be paid to secure a license number, such number being good as long as the person who takes it out owns the car. If the car is sold at any time the license is void and a new one necessary.

15,485 Employees in N. Y. Plants

—

Twenty-six Automobile and Parts Makers' Wages increased 10% in Sept.

NEW YORK CITY, Oct. 28—Evidence that the automobile and parts manufacturers in New York State have made a large increase in activity and an improvement in business, which has been manifest all summer, appears in returns received by the State Industrial Commission from representative manufacturers throughout the State. In its September returns it had reports in the automobile group for twenty-six firms with 15,485 employees in the State. All but five of these firms were engaged in the manufacture of automobiles or parts. All these five firms together had less than 1000 employees.

In July, 1915, 2.3 per cent more people were employed than in June; in August 1.5 per cent more than in June; and in September 14.4 per cent over June. Comparing returns for each month this year with the corresponding month last year a remarkable improvement since last year appears; June returns show 27.2 per cent more employees this year than last; July returns show 32.1 per cent more employees; the August returns 30 per cent more employees, and the September returns 47.4 more employees than last year.

A large increase in wages was made. Figures for that item show a progressive increase from June to September this year, 10 per cent more wages being paid in the middle week of September this year than in the middle week of June. For the middle week of each month this year as compared with last, in June 35.6 per cent; in July 33.1 per cent; in August 42.9 per cent; and September 46.5 per cent more wages were paid this year than last.

As indicating how the improvement in that industry compares with the improvement for manufacturing in general, the following figures show returns indicating 1 per cent fewer employees in July; 2 per cent fewer in August; but 4 per cent more for September of this year as compared with June of this year. In comparing this year with last there were 2.4 per cent fewer employees in June; in July 0.2 per cent more; in August 4.4 per cent more; and in September 5.4 per cent more employees this year than last.

Western Tire Co. Now General Rubber Mfg. Co.

KANSAS CITY, MO., Oct. 27—The Western Tire & Rubber Co., this city, is building a three-story factory at Akron, Ohio, where it will move its plant Dec. 1. The company has been re-incorporated under Ohio laws, under the name of the General Rubber Mfg. Co. and the capital has been increased to $200,000.

The company will continue to make the K. C. line of tire accessories. In addition to this, it is adding equipment to make 400 tires a day. The new plant will be in full operation by Jan. 1. The personnel of the company will remain unchanged.

—

Crowther Builds Model Cars

ROCHESTER, N. Y., Oct. 29—The Crowther Motor Co., whose factory is located at Ridgway and Woodrow Avenues, is making progress in construction work as reported in THE AUTOMOBILE for Oct. 28. The model cars are under construction and will be exhibited at the winter shows. The cars are expected to sell at $550, this including electric starter, lights, demountable rims and speedometer. The line will include a roadster touring car and a 1200-lb. delivery wagon. In these the transmission system of Charles E. Duryea, pioneer automobile manufacturer, will be used, in which the drive is direct into the rims of the two rear wheels, thus eliminating gearset, clutch and differential, as well as the live type of rear axle. It is expected to have a production of fifty to sixty cars per day after April 1.

—

Will Make Gas-Electric Truck

MILWAUKEE, WIS., Oct. 29—The National Brake & Electric Co., Milwaukee, Wis., is engaged in the development of a new heavy duty motor truck of the gas-electric type, said to be particularly adapted for use on the war front. The company is part of the Westinghouse group. No information relative to the new product will be given out until development work is completed. The National company manufactures compressors, gasoline locomotives, air brakes and electrical appliances and is the specialty plant of the Westinghouse company. Since July 1 the Milwaukee works force has been increased from 700 to 1000 men.

—

Bosch Gets Nine Contracts

NEW YORK CITY, Nov. 1—The Bosch Magneto Co. has closed contracts with the following concerns to use Bosch magnetos for the coming season: Chandler Motor Car Co., Cleveland, Ohio; Crawford Automobile Co., Hagerstown, Md.; Continental Motor Mfg. Co., Detroit; Ohio Armleder Co., Cincinnati, Ohio; Palmer-Meyer Motor Car Co., St. Louis, Mo.; H. E. Wilcox Motor Co., Indianapolis, Ind.; U. S. Motor Truck Co., Cincinnati, Ohio; Hendrickson Motor Truck Co., Chicago, Ill.; Alamo Mfg. Co., Hillsdale, Mich.

Detailed Export Statistics for August and 8 Months Show Big Gains

United Kingdom Retains First Place with 2290 Cars Worth $3,530,831 in August—Increases in Shipments to West Indies, Asia, Oceania and Other Countries

WASHINGTON, D. C., Nov. 1—As indicated in a recent issue of THE AUTOMOBILE the exports of automobiles continue to grow so rapidly that even those in close touch with the industry are astonished. The gross figures for August and the eight months ended August, with figures for the corresponding periods of last year, have already been published.

The Department of Commerce to-day announced that September automobile exports were 2227 commercial vehicles, value, $5,882,255; pleasure cars, 4299, value, $3,215,459; parts, $1,613,419.

Detail figures show exports of commercial cars rose from sixty-six, valued at $124,016, in August, 1914, to 1614, valued at $4,387,193 in August last, while during the eight months' period they increased from 509, valued at $772,257, in 1914, to 15,042, valued at $41,886,961, in 1915. Exports of passenger cars likewise increased from 385, valued at $441,879, in August last year, to 3,839, valued at $3,121,834, in August last, and from 18,884, valued at $16,612,060, in 1914, to 26,736, valued at $23,576,188, in 1915.

United Kingdom Best Customer

Naturally, the United Kingdom retains first place in the volume of its imports of cars from this country, the figures showing that during August a year ago, twenty-seven machines, valued at $38,500 were exported to King George's domain, while during August last the number had increased to 2290 and the value to $3,530,831. During the eight months' period the number of cars exported increased from 4994, valued at $4,126,263, in 1914, to 16,784, valued at $25,528,943 in 1915.

There were no cars exported from this country to France in August, 1914, while in August last the number was 196 and the value $661,972. During the eight months' period the number rose from 1044, valued at $625,636, in 1914, to 4464, valued at $11,209,798 in 1915.

Germany failed to receive any cars from this country, and during the eight months' period the imports from this country fell from 1063 cars, valued at $799,552, in 1914, to four cars valued at $2,800, in 1915.

One car, valued at $1,000, was exported to Italy in August, 1914, while in August, 1915, the number had grown to thirteen and the value to $11,203. The eight months' period showed a decline from 229 cars, valued at $148,388, in 1914, to 121 cars, valued at $74,498, in 1915.

Other European Gains

Under the heading "Other European Countries," a big gain in exports is in-

dicated. In August a year ago the exports from this country amounted to twelve cars, valued at $10,533, while in August last the number was 722 and the value $1,652,280. The figures for the eight months' period were 2378 cars, valued at $1,886,647, in 1914, and 5544 cars, valued at $14,741,288, in 1915.

There were 238 cars, valued at $377,821, shipped to Canada in August a year ago, while in August last the number had increased to 721 and the value to $480,677 in August last. This increase, however, was not maintained during the eight months' period, the number of cars exported to our Northern neighbor in 1914 being 3594, valued at $4,447,442, while in 1915 the number was 4682 but the value was only $3,673,203.

War-ridden Mexico took eight cars, valued at $9100 from this country in August last, as against six cars, valued at $4,400 in August a year ago. During the eight months of this year the exports of cars to that country amounted to sixty-nine, valued at $65,406, while during the corresponding period of last year the number was sixty, and the value $70,374.

West Indies Buy More

The West Indies and Bermuda are beginning to appreciate American-built motor cars, the export figures showing an increase from thirty-two cars, valued at $19,247, in August, 1914, to 368 cars, valued at $193,725, in August last, and from 352 cars, valued at $305,310, in 1914, to 2072 cars, valued at $1,110,173, in 1915.

Increased exports to South American countries are also shown in the latest table of statistics. In August a year ago, nineteen cars, valued at $13,288, were shipped to various South American countries, while in August last, the number had increased to 274 and the value to $149,319. During the eight months' period the exports increased from 891 cars, valued at $722,527 in 1914, to 1486 cars, valued at $793,037, in 1915.

Increase for Oceania

British Oceania continues to be a good customer for American cars, the exports having increased from seventy-nine cars, valued at $60,562, in August, 1914, to 391 cars, valued at $322,689, in August last, while during the eight-month period the number of cars exported increased from 2666, valued at $2,294,033, in 1914, to 2760 cars, valued at $2,368,736 in 1915.

Fourteen cars, valued at $19,404, were exported to Asia and other Oceania in August a year ago, while in August last the number was 330 and the value $393,771. During the eight months' period the exports rose from 1193 cars, valued at $1,129,405, in 1914, to 2508 cars, valued at $4,703,181, in 1915.

S. A. E. Winter Meeting Program

Electrical Equipment of Cars To Receive Marked Attention on Jan. 5 and 6

NEW YORK CITY, Nov. 1—The 1916 Winter Meeting of the Society of Automobile Engineers will be held in the Engineering Societies Building, this city, Wednesday and Thursday, Jan. 5 and 6.

At the first session of the society meeting, to be held on Wednesday morning, business matters and reports of divisions of the standards committee will be submitted and discussed. For the sessions to be held on the morning and afternoon of the following day, Thursday, papers on current subjects of special significance are scheduled.

It is the purpose of the Council and the Meetings Committee that the coming meeting shall be shorter than the annual meetings of previous years, in order to afford the members an opportunity to concentrate their attendance on fewer sessions during the much occupied time of Show Week. It is believed that the papers to be presented will be of sufficient interest and merit to bring about a good attendance and valuable discussion.

A large portion of the meeting will be devoted to consideration of matters connected with the electrical equipment of gasoline cars.

Battery vs. Magneto Ignition

Comprehensive consideration will be given to the points involved in and the relative merits of magnetos and batteries as sources of ignition. Among those who will present statements in connection with this timely matter are Alexander Churchward; Frank Conrad; Dr. R. H. Cunningham, and E. Gassmann.

Electric Lighting and Starting

Joseph Bijur will present a paper entitled Electric Lighting and Starting for Automobiles, taking up among other topics the desirable characteristics and cranking speeds of starting motors.

Electric Bulbs

Henry Schroeder will present data on Electric Bulbs for Automobiles, indicating the various properties and efficiencies desired and to be expected. The paper should be of a great deal of benefit generally to automobile engineers engaged in the design and production of gasoline and electric vehicles, as well as in connection with the work of the Electrical Equipment Division.

Sulphur Content in Steel

Dr. J. S. Unger will read a paper on the Effect of Sulphur Content in Steel, giving the results of exhaustive tests. Discussion of this subject should result in the acquisition of fundamentally valuable information.

It is possible that a few more papers will be added to the program, but the principal idea of the committee is to have only subjects of unusual importance presented and that sufficient time shall be allowed for as thorough discussion of these as may be desired.

The annual dinner will be held at the Plaza Hotel on the evening of Thursday, Jan. 6. Tickets are $5 each.

Standards Committee Meeting

A meeting of the standards committee will be held at the rooms of the society in New York on Tuesday morning Jan. 4. All members of the society may attend this committee meeting.

—

Detroit S. A. E. to Hear Diamond on Piston Design

DETROIT, MICH., Nov. 1—At the next meeting of the Detroit section of the Society of Automobile Engineers, to be held Nov. 12 in the convention hall of the Pontchartrain hotel, the feature will be a talk by J. E. Diamond of the Aluminum Castings Co. on the subject of Piston Design and Its Relation to the Cothias Process. Mr. Diamond's talk will cover piston design in general, as well as the aluminum alloy piston.

—

Detroit Committee on S. A. E. Cruise

DETROIT, MICH., Nov. 1—Chairman George W. Dunham, of the Detroit Section of the Society of Automobile Engineers, has named W. A. Brush and Mason P. Rumney, to serve with him as the committee in charge of the next summer's annual cruise of the society. The committee is already at work.

Since the September list of contributors to the maintenance fund of the Detroit section of the society was published, two new concerns have been added to this list, the Electric Storage Battery Co. has pledged $100 and the Doehler Die Castings Co. $50. The total pledged to Oct. 15 being $2,850.

—

Moline Plow to Continue Buggies

MOLINE, ILL., Nov. 3—The Moline Plow Co., whose entrance into the automobile field with a new passenger car was announced recently, wish it to be understood that in so doing they are not relinquishing the buggy business which will be continued as usual.

—

Grant Adds an Acre

FINDLAY, OHIO, Nov. 1—The Grant Motor Co. is building three large additions to their North and South plants in this city. All are one-story and cover an acre of floorspace. The company is greatly hampered for space.

Gasoline Is Higher in West

Since March Average Increase Throughout Country Is 4 Cents per Gal.

NEW YORK CITY, Oct. 29—Gasoline prices continue to rise throughout the West, the latest advance being that in Cleveland where Standard Oil has raised its price per gallon 1½ cents to 14 cents to garages. The independents have met the increase by an advance of 1 cent a gallon to 14 cents. White Rose brand gasoline of the National Refining is now quoted at 16½ cents a gallon, an advance of 3 cents. The price of retail trade is 1 cent higher than these quotations. In March the garage price was 11 cents, and there was no change in price until Sept. 9.

The average increase throughout the country has been about 4 cents a gallon since March. In the past six weeks gasoline prices at the various cities have been advanced two or three times. This week there has been an increase in price from 1 to 3 cents a gallon in the principal cities of the country, including Portland, Los Angeles, Seattle, Minneapolis, San Francisco, Detroit, Kansas City, St. Louis, Chicago, Louisville, Denver and Cleveland. The oil experts attribute the advance to the increase in automobiles, the general increase in demand for gasoline and the fact that production has not been increased.

The Standard Oil Co. of Indiana last week, increased the price of gasoline in St. Louis 1 cent to 13 cents to automobile owners and 11.9 cents to tank owners. This follows the advance in Chicago of 1 cent to 12½ cents and 11½ cents respectively.

St. Louis jobbers estimate that the fight between the Standard Oil Co. of Indiana and the independents which commenced last May has netted the Standard Oil nearly $90,000,000. About half of this represents the increase in the price of crude oil, of which the company bought nearly 67,000,000 barrels, which oil is still in the company's tanks. The other half has been made by buying all gasoline from the independent refiners in the Cushing oil field.

Gasoline prices in Cincinnati have been advanced 3 cents a gallon to 15 cents, and further advance is looked for. This price is for tank wagons. To wholesalers the price is 14 cents, although on contracts to wholesalers deliveries are being made at lower prices. The price in March for tank wagons was 12 cents and the wholesale price was 11 cents.

The Continental Oil Co. and the Midwest Refining Co. in Denver have advanced the price 1 cent to 17 cents a gallon to tank wagons and 16 cents to garages.

Louisville gasoline now quotes at 13½ cents a gallon on tank wagons, compared with 11 cents at the end of last March.

The accompanying table gives the current price in cents per gallon on a tank wagon or garage basis in the larger cities in the United States. This is compared with the price on March 31 and the advance in cents per gallon. This price is several cents below what the consumer has to pay for his gasoline, that depending on the quality of the fuel, etc.:

Metal Prices Higher

NEW YORK CITY, Nov. 1—Market quotations last week were higher, especially in the metals. With the exception of antimony, all the metals showed substantial gains, with open-hearth steel the feature. This rose $2.00 per ton, closing on Saturday at $26.00. Bessemer steel closed on Saturday at $25.00 per ton; or 50 cents higher than the opening on Tuesday. Both electrolytic and Lake coppers rose ¼ cent a lb., both closing at 18. Lead saw a gradual rise throughout the week and closed at $4.90 or a gain of 15 cents per 100 lb. Tin fluctuated throughout the week, its highest mark being $34.75 and its lowest $33.75, quoted on Tuesday. It closed on Saturday at $34.75 at a gain of $1.00 per 100 lb.

In the oils and lubricants markets, two noticeable changes occurred, fish oil, Menhaden, rose to 45 cents at a gain of 3, and Pennsylvania petroleum rose 5 cents a barrel, closing at $1.80.

Federal Trade Commission to Investigate Gasoline Prices

WASHINGTON, D. C., Oct. 30—Request has been made of the federal trade commission to institute an investigation of charges that illegal practices prevail in the marketing of gasoline. Price fluctuations have been brought to the attention of the commission, which, it is declared, are not explained by the difference in freight rates between the cities where the varying prices exist. A thorough investigation of the matter is to be made by the commission.

Tire Sales Large—Manufacturers Increase Production

NEW YORK CITY, Oct. 29—Tire companies in this country are doing a large business. Heavy home sales of automobiles and the war's demands have brought about this prosperity. About 14,000 tires a day are being turned out by the B. F. Goodrich Co.; Goodyear is turning out about 10,000 and the U. S. Rubber is now making 8000 and this amount will shortly be increased to 10,000. The Kelly-Springfield company will be producing 1500 a day by Dec. 1. The company has purchased a new plant at Wooster to take care of its production.

At Akron operations are continued on a 24-hr. schedule and the company is so far behind its orders that capacity operations are certain on the same 24-hr. schedule throughout the remainder of the year.

It is said that the increase in the cost of fabric and crude rubber will possibly decrease the net earnings of the tire makers in the closing half of 1915, as compared with the first half. Fabric is now selling approximately 25 per cent above the price prevailing early in the year. Crude rubber is close to 10 per cent higher.

—

Hess-Bright Issues Licenses

PHILADELPHIA, PA., Oct. 29—The Hess-Bright Mfg. Co., this city, has issued licenses covering the manufacture of ball bearings after the Conrad patent, to the Standard Roller Bearing Co., Philadelphia, Pa.; the New Departure Mfg. Co., Bristol, Conn.; the Gurney Ball Bearing Co., Jamestown, N. Y.; and the U. S. Ball Bearing Co., Chicago, Ill.

—

Penberthy Gets Carbureter Rights

DETROIT, MICH., Nov. 1—The Penberthy Injector Co. has secured the right for the Ball & Ball carbureter in U. S. and Canada and is now manufacturing the device. F. H. Ball and his son F. O. Ball, formerly connected with the Ball Engine Co., Erie, Pa., have been retained as engineers.

—

Dividends Declared

B. F. Goodrich Co., Akron, Ohio, regular quarterly of 1¾ on preferred, payable Jan. 1 to stock of record Dec. 21.

Tire Issues Feature Market

—

Firestone Reaches 790 Mark—Kelly-Springfield Closes at 300 with 53 Point Gain

NEW YORK CITY, Nov. 1—The drop in Studebaker and the record rise in Firestone and Kelly-Springfield Tire common featured last week's security markets. A rally occurred at the close on Friday after a sharp decline, the crisis in the French cabinet occurring opportunely with a general strengthening of the market. There was heavy liquidation during the earlier hours on Friday, the rally setting in late in the afternoon. At one time the drop in Studebaker reached a total of 21½ points, striking terror in those who have been following the advance. However, the stock picked up and closed on Saturday at 172, just 16 points under last week's mark. Firestone common kept up its record rise and reached on Saturday the high mark of 790 with a 70-point rise for the week. Kelly-Springfield common reached the 300-point mark at the close on Saturday, a gain of 30 points for the week.

—

General Motors Strong

General Motors was the strongest feature on Saturday, advancing 34½ points during the day to 390 on the probability of early inauguration of regular dividend payments. The week's rise was 20 points.

Paige-Detroit went up 20 points, closing at 460. Chevrolet closed at 130, a 5-point gain. Maxwell stocks showed substantial gains, the common rising 8¾ points, the first preferred 3¾ and the second preferred 7½.

The 550-point rise of Canadian Ford featured the inactive stocks in the Detroit Stock Exchange. This stock last week dropped 50 points. In the active Detroit stocks, the 25-point rise in Paige-Detroit common and the 20½ point drop in Studebaker common were the features. General Motors common dropped to 350, a loss of 16 points.

—

Maxwell Meeting Postponed Until Nov. 10

NEW YORK CITY, Nov. 1—A special meeting of the holders of the stock trust certificates of the Maxwell Motor Co. has been postponed until Nov. 10. The meeting was called to ratify the plan recently submitted by the directors for the retirement of the accumulated 14¼ per cent back dividends on the first preferred stock by the issue of non-interest-paying warrants convertible into first preferred stock at par and to authorize the issue of $1,050,000 additional stock of the same class.

—

Van Blerck Motor to Expand

MONROE, MICH., Nov. 1—Fifty per cent of the capital stock of the Van Blerck Motor Co., this city, has been secured by Eastern capital, and $150,000 additional stock will be issued. New land will be purchased, it is announced, and the factory enlarged to three times its present size. The present officers will remain until a reorganization is effected.

200,000 See Cars at Dallas Show

$1,000,000 Worth of Cars Displayed by 30 Exhibiting Dealers

DALLAS, TEX., Oct. 25—With $1,000,000 worth of automobiles on display, the third annual automobile show by the Dallas Automobile Dealers' Association is on. It opened with the Texas State Fair, Oct. 16, and will be concluded Sunday, Oct. 31. The show is significant for several reasons, first that this is the second showing of 1916 models in the United States, the first having been at Milwaukee; second, for the reason that during the first nine days of the show, more than 200,000 visitors, many of them farmers interested in the use of automobiles, passed through the automobile exhibit building. Of this great mass of visitors at least 50,000 stopped and asked questions regarding the merits of the various cars.

There were thirty exhibitors in the automobile exhibit building and every foot of space was occupied. Had the building been larger, the space could have been profitably used, as the Wichita Motor Co. and several others were compelled to seek space in adjacent buildings. The automobile building was erected three years ago. It cost $17,500 and is 149 by 264 ft., built of wood and concrete with concrete floors, large plate glass windows and several skylights.

Plans are to be made for an addition to the building before the next automobile show. The present affair cost the local dealers approximately $30,000. Of this expense, each dealer bore his share. No admission fee was charged this year, believing that without such there would be more visitors to the building.

—

173 More Accessory Exhibitors for Chicago and New York

NEW YORK CITY, Oct. 27—One hundred and seventy-three additional accessory exhibitors have been granted space at the New York City and Chicago automobile shows, Dec. 31-Jan. 8 and Jan. 22-29. One hundred and three of these are in New York and seventy-four in Chicago. This makes the total list of accessory exhibitors for New York 196 and for Chicago 153.

Additional Accessory Exhibitors

Able Engine Co., Inc.....New York City
Ahlberg Bearing Co.....Chicago, Ill.
American Die & Tool Co.....Reading, Pa.
American Express Co.....New York City
American Taximeter Co.....New York City
Apex Elec. Mfg. Co.....Chicago, Ill

Wood Mfg. Co.....Fairfield, Conn.

Ohio Garagemen Organize

85 Discuss Business Problems at Session—Many Papers Read

COLUMBUS, OHIO, Nov. 1—Garagemen of the State of Ohio organized the Garage Owners' Association of Ohio, at the organization meeting held here Oct. 26 and 27. All told, some eighty-five garage owners and dealers attended the meeting.

In addition to welding themselves together into a powerful working unit, the garagemen also placed themselves on record as favoring the passage of the Stevens Bill, which would permit price maintenance; they also urged, through resolutions, that the National Automobile Chamber of Commerce take up again the question of setting a uniform time for the anouncement of new car models.

The Columbus organization was assisted in the formation of the State association by E. J. McGuirk, organizer for the Associated Garages of America, who gave the benefit of his experience. Aiding him were J. C. Thorpe, president of the Champaign County Automobile Trade Association, of Urbana, Ill.; L. C. Steers, secretary of the Garage Owners' Association of Michigan, and Jud S. Joslyn, of the Motor Car Dealers' Association of Rockford, Ill.

—

Buick To Build Foundry

FLINT, MICH., Oct. 30—The Buick Motor Co. has arranged for the construction of a new two-story foundry, 530 by 300 ft. to be made of concrete and steel. It will be one of the largest and best equipped foundry buildings in the world and is expected to have an output capacity of at least 200 tons of castings a day. Several hundred men will be added to the working force when the plant is completed, which is expected to be about May 1, 1916.

The old foundry may be taken over by the Weston-Mott Co.

—

New Plant for Detroit Battery

DETROIT, MICH., Oct. 30—The Detroit Battery Co. now located at 607 Fort Street, West, will have a three-story plant at 104 High Street. Ground will be broken in a few days and the factory is to be ready for occupancy by Jan. 1. The structure will be 70 by 100 ft. About 150 men will be employed.

—

L. P. C. Men Find Work

RACINE, WIS., Oct. 29—All of the 280 mechanics employed by the L. P. C. Motor Co., Racine, Wis., which recently made an assignment in favor of credi-

tors, have received their wages in full and obtained immediate employment in similar industries in Racine, Kenosha and neighboring cities where the demand for skilled help cannot be filled. Fifty of the best men went into the Thos. B. Jeffery Co. plant at Kenosha on the day following the cessation of operations in the L. P. C. works. It is stated on good authority that creditors are trying to arrange matters so that the plant and its valuable equipment will be kept intact and the manufacture of motor cars resumed at an early date. F. Lee Norton of Racine is in charge as assignee.

17,255 Cadillac Eights in Year

DETROIT, Oct. 30—Since the Cadillac Motor Car Co. shipped its first eight-cylinder, Oct. 10, 1914, the company has built and shipped 18,159 cars to Oct. 23, 1915. During the year, starting from the day the first eight was shipped to Oct. 9 of this year, the number shipped was 17,255. The re-equipment of the plant with new machinery, new tools, took much more time than had been anticipated and therefore production was greatly hampered during several months.

Carriage Factories, Ltd., Forms Canadian Briscoe Co.

MONTREAL, QUE., Oct. 30—Carriage Factories, Ltd., of Canada, has formed the Canadian Briscoe Co. as a subsidiary. The latter will assemble the parts in Canada from the American Briscoe company, the cars of which will be sold through the Carriage Factories company.

This company has acquired the carriage manufacturing end of the McLaughlin Motor Car Co.

Studebaker Adds 52,500 Sq. Ft.

DETROIT, MICH., Oct. 30—A three-story building, 50 by 350 ft. for tuning cars before they are shipped, will be erected by the Studebaker Corp., adjacent to its plant No. 3. It will cost about $75,000. Other new structures are planned. Several now in course of construction will soon be ready for occupancy. The corporation reports that several hundred dollars were paid as premium to advance delivery of the structural steel material.

Chalmers Workers Form Clubs

DETROIT, MICH., Oct. 29—After hearing Hugh Chalmers, president of the Chalmers Motor Co. talk to them about looking ahead to the future and what could be done in this respect by getting together, by organizing, the office and shop workers of the Chalmers Motor Co. organized two clubs, Young Men Chalmers Club and Young Women Chalmers Club, both of which will be directed or run by the office and shop workers.

Apperson to Add 12 Acres

Floorspace Will Total 1,000,000 Sq. Ft.—Production to Be 10,000 Cars

KOKOMO, IND., Oct. 29—The Apperson Bros. Automobile Co., this city, will add floorspace totaling 500,000 sq. ft. or approximately 12 acres. The production is to be 10,000 cars. This additional floorspace will increase the total number of square feet to a million.

Work is already under way on two new buildings, which are being constructed at location of plant No. 2. These buildings will afford an additional space of 150,000 sq. ft., and will cost $75,000. The company is laying plans for an expenditure of $200,000 in new equipment.

Springfield Body May Move

SPRINGFIELD, MASS., Nov. 1—Without giving their employers an opportunity to arbitrate, 350 employees of the Springfield Metal Body Co. went out on strike, demanding an 8-hr. day and recognition of the Union. For some time the removal of the plant to Detroit has been contemplated in view of the fact that a large part of the company's business is now with Detroit car manufacturers. Unless the strikers return to work, it will be necessary to remove the machinery at once so that the company can fill orders for quick delivery.

$1,000,000 Building for Touraine

PHILADELPHIA, PA., Oct. 31—Plans have been completed and the work of construction will begin immediately on a building which has been leased to the Touraine Motor Co.

The lease taken by the Touraine company is for a period of twenty years and the total rental will be $1,600,000.

The building will be six stories high, with a basement, of steel and reinforced concrete, with exterior walls of white glazed terra cotta and white brick, and with the ground, representing a total expenditure of $1,000,000. It will have a frontage of 400 ft. on Market Street, 250 ft. on Twenty-third Street, 400 ft. along the Pennsylvania Railroad and 155 ft. along the Baltimore & Ohio Railroad. Each floor will have 70,000 sq. ft. of space and there will be four elevators, each 22 by 10 ft.

Edwards Carbureter Tested on Buick Six

CHICAGO, ILL., Oct. 28—The Edward's carbureter was introduced to Chicago to-day by an economy, speed and acceleration test conducted by the Technical Committee of the Chicago Automobile Club under sanction of the American Automobile Association. An economy of 28.9 miles per gallon and a speed of 58 m.p.h. with the same carbureter setting was obtained on a Buick small six.

The economy run was made over Chicago's boulevard system with a route arranged so that the car went approximately an equal distance in all four directions. A measured gallon of Red Crown gasoline having a gravity of 59.1 deg. Baumé at 60 deg. Fahr. was poured into a special tank, and the run made at a speed of 20 m.p.h. until the fuel was exhausted at 28.9 miles.

In acceleration tests, the car was put from a standstill to 25 m.p.h. through the gears in 11 and 1-5 sec. On high gear, it accelerated from 5 to 25 m.p.h. in 11 and 4-5 sec.

The National Carbureter Co., manufacturer of the carbureter, made the test. The instrument was designed by W. A. Edwards, formerly connected with Rayfield and Stromberg factories.

Willard Opens Two Branches and Ten Service Stations

CLEVELAND, OHIO, Oct. 29—The Willard Storage Battery Co., this city, has opened branches in San Francisco, Cal. and Atlanta, Ga. The San Francisco branch at 1433 Bush Street, 15,000 sq. ft. of floorspace. The Atlanta quarters are located at 8-10 East Cain Street.

Ten new service stations have recently been established bringing the total to 544. The ten new stations are as follows: Wayne Electric Co., Wooster, Ohio; Citizens Garage, Laredo, Tex.; Continental Auto Parts Co., Franklin, Ind.; Shepard Garage, Jerseyville, Ill.; William L. Clark, Seymour, Ind.; J. E. Rogers, Ft. Morgan, Col.; Hartman Bros., Montrose, Cal.; Albany Storage Battery Co., Inc., Albany, N. Y.; F. A. Harrison, Ridgewood, N. J., and Battery & Elec. Serv. Station, Mason City, Ia.

Wilson Sells Studebaker Agency

PHILADELPHIA, PA., Oct. 30—O. S. Wilson, for the past two years Philadelphia agent for the Studebaker car, has sold out his interests to a new concern, taking effect Nov. 1. Mr. Wilson had been a Studebaker man for a number of years.

Simms Magneto Enlarges

EAST ORANGE, N. J., Oct. 30—The Simms Magneto Co., this city, will build two additions to its plant, one to cost $10,000 and the other $5,000. Work will be started in the near future.

Aluminum Goods Adds Again

MANITOWOC, WIS., Nov. 1—The Aluminum Goods Mfg. Co., Manitowoc, Wis., which made important improvements and additions to its plant some time ago, has broken ground for another large factory addition and when this is completed

will undertake the erection of a new warehouse and shipping room. The factory addition will be five stories high, 53 ft., 6 in. by 300 ft., of brick and steel with mill floors. The investment in the addition will be approximately $100,000.

To Sell Morgan-Marshall Plant

EAST LIVERPOOL, OHIO, Oct. 29—The manufacturing plant, together with all of the equipment of the Morgan-Marshall Co-operative Rubber Tire Co., in this city, will be offered at public sale by Sheriff Crawford at an early date. It has been appraised at $60,000, and will be sold on the premises.

Lima Crucible Steel Expands

LIMA, OHIO, Nov. 1—The Crucible Steel Co. of Lima will increase its capital from $50,000 to $100,000 and a new $30,000 addition will be built to the local plant at once. Seventy men will be added to the working force. The company turns out steed castings and parts for automobiles.

Overland to Increase Force

TOLEDO, OHIO, Oct. 29—Ten thousand additional men are to be employed by the Willys-Overland Co., just as soon as new additions now under construction, and others to be started at once are ready for occupancy. The output of automobiles is to be increased 1000 a week.

Mitchell-Lewis Takes Inventory

RACINE, WIS., Oct. 29—The Mitchell-Lewis Motor Co., Racine, Wis., is taking inventory this and next week (Nov. 1 to 13) and in order to keep production at the highest level possible, only part of the departments are closed down at one time.

A. Elliott Ranney Adds Daniels 8

NEW YORK CITY, Oct. 30—The Daniels eight will be handled in New York City by the A. Elliott Ranney Co., Fifty-second Street and Broadway.

Randall Opens Advertising Agency

DETROIT, MICH., Nov. 1—Fred M. Randall has resigned from The Taylor-Critchfield-Clague Advertising Agency, and has started his own agency, the Fred M. Randall Co., with headquarters at 605 Ford Building, this city.

Strike in Kundtz Body Plant

CLEVELAND, OHIO, Nov. 1—A strike by 3000 employees of the big woodworking plant of Theodore Kundtz, maker of automobile bodies and parts is said to endanger thousands of dollars' worth of orders for war trucks in Cleveland automobile factories.

Labor leaders declare the Kundtz plant makes bodies for practically every big automobile factory in Cleveland operating largely on war orders.

New Studebaker Policy

Will Hold Conferences of Branch Mgrs. and Dealers Where Branches Are

DETROIT, MICH., Oct. 28—The Studebaker Corp. has inaugurated a new policy with regard to branch managers and dealers getting together with the factory officials for general conference or convention purpose. Heretofore the dealers and branch managers came to the administration offices in South Bend, Ind., to confer with the officials. Much good resulted, but, at the same time, it was not realized sufficiently that the time thus spent by the dealer away from his place of business was possibly causing him a loss, as very often these meetings were held at the busiest time of the dealer's season.

Now the officials of the Studebaker Corp. have decided to try the other way and instead of having the dealers and branch managers come to them they are going to them. There will be conferences of the men in the cities where Studebaker has branches and where it will be easier to get the men of the district or territory together.

The first of these conference meetings was held in Chicago this week, when about fifty Studebaker dealers from Illinois, Wisconsin and Indiana met and discussed matters concerning advertising campaigns, selling methods, production and other matters of interest to them.

The officials of the corporation who attended the meeting included A. R. Erskine, president; L. J. Ollier and James G. Heaslet, vice-presidents; Henry T. Meyers, manager of the commercial car department. Others who traveled with the Studebaker party were: J. E. Grady, sales manager for Canada; R. H. Williams, manager of the Detroit branch; H. V. Blevins, distributor for the State of Ohio; L. Davis, of the Cleveland district headquarters; F. H. Peck, dealer in Grand Rapids, Mich.; H. A. Biggs, of the Frank Seaman, Inc., advertising agency.

The party is making the trip in a special Pullman and will stop for conference purposes in Minneapolis, Omaha, Kansas City, St. Louis. The branch manager and dealer in each city visited will be taken along to the next stopping place.

Randolph Builds Trailers

JONESVILLE, MICH., Oct. 28—The Randolph trailer is made by H. C. Randolph, successor to the Standard Auto Trailer Truck Co. It sells for $45 and upwards, according to load capacity, steel or rubber tires and the kind of axle.

There is only one model G, but it is made in four different sizes as far as loading capacity is concerned. The trailer with a 1000 lb. capacity has 1⅛ in. steel or rubber tires; the one with a capacity of 1300 lb. has 1¼ in. steel or rubber tires; with a load capacity of 1600 lb. the tires are 1⅜ in. steel or rubber, and they are 1½ in. rubber or steel, for the trailer carrying 2500 lb. There are two series, the first one having a D. C. axle and the second series a Timken.

85 Per Cent Dividend for Milwaukee Exhibitors

MILWAUKEE, WIS., Nov. 1—Results from the show held by the Milwaukee Automobile Dealers, Inc., at the State fair grounds are very encouraging and the undertaking was so successful as an attraction for the State fair that the agricultural commission has offered to set aside the same building for the show next year. The show was open five days and during that time the total attendance was 40,000, of which 27,000 was paid attendance, mostly farmers; between 400 and 500 dealers outside of Milwaukee attended. The payment to the State fair for the use of the building was $3,000 and the receipts from the sale of space and tickets were $6,021 and $2,700, respectively. In consequences, a dividend amounting to 85 per cent of the cost of space was returned to each exhibitor.

Larger Quarters for Quaker Show

PHILADELPHIA, PA., Oct. 30—Philadelphia's fifteenth annual automobile show, Jan. 8 to 15, will be held in Convention Hall, northeast corner of Broad Street and Allegheny Avenue, much further uptown than any previous event of its kind. However, there will be a floor-space of 60,000 sq. ft. as compared to 27,000 last year, when the show was held in the Metropolitan Building. No trucks will be shown.

Warner Trailer Enters Field

BELOIT, WIS., Oct. 29—A. P. Warner of Beloit, Wis., well known as one of the founders of the Warner Instrument Co., now the Beloit Works of the Stewart-Warner Speedometer Corporation, Chicago and Beloit, has developed a light trailer truck for automobiles and is about to engage in the manufacture of the appliance on a large scale.

Michigan Truck & Lumber Adds

HOLLY, MICH., Nov. 1—A one-story addition 70 by 176 ft. will be started at once at the plant of the Michigan Truck & Lumber Co. which, in addition to doing contract work for the Ford Motor Co. has recently closed contracts with the Buick, Hudson and Maxwell companies in Detroit and Chandler in Cleveland.

Vehement Discussion of Eight Paper

Crawford's Contentions Attacked By Indiana Engineers—Acceleration Tests on Speedway and Examination of Stripped Peugeot Provide Full Afternoon Program

INDIANAPOLIS, IND., Oct. 30—The eight-cylinder side of the eight versus twelve argument was presented last night to the members of the Indiana section of the Society of Automobile Engineers and the visiting engineers at the meeting of the section at the Claypool Hotel last night, Charles S. Crawford, chief engineer, Cole Motor Car Co., took up the cudgels in behalf of the eight-cylinder engine in reply to the arguments for the twin-six presented by Jesse G. Vincent, vice-president of engineering, Packard Motor Car Co., to the Detroit section Sept. 16, and to the Indiana section Sept. 24.

Representative Attendance

Prospects of an interesting and illuminating argument on multiple-cylinder engines together with the afternoon feature of acceleration and speed tests of eights and twelves on the speedway and a view of the Peugeot driven by Aitken at Sheepshead Bay, which was disassembled for the purpose, brought out a large and representative gathering. Every motor car manufacturing center was represented by engineers from some of the factories. Chairman Moskovics and Secretary Combs had done such good publicity work that there were in the neighborhood of 300 engineers in attendance.

Acceleration Studied

The afternoon session at the speedway proved an interesting one as twelves, eights and sixes were given tryouts for speed, acceleration and low-speed running. National twelves, Cole eights, Haynes, Marmon and Dorris sixes were put through their paces for the visiting engineers. After that they were taken to the Prest-O-Lite plant where the Peugeot racing car was torn down for their edification, as one of the best examples of motor car engineering.

Before taking up Crawford's paper, the suggestion was made by W. G. Wall of the National company that the section appoint a committee to develop a standard method for conducting acceleration tests. He stated that there were other factors than the actual time element required to increase speed from one definite point to another to be taken into consideration and cited that it was possible to cut down the flywheel weight and get very good acceleration, but the lower flywheel weight would give poor idling. He suggested that the section get up a formula which would take in such factors as wheel sizes, gear ratios, and so on, that what the owner wanted was low-speed ability as well as rapid acceleration.

In confirming this, Howard Marmon of Nordyke & Marmon stated that the owner availed himself most of the car's ability to get from one speed to another and there was needed a standard definite way to compare cars on that basis; the society should standardize the means for such comparison. He believed that the speedometer and stop watch while not giving precise results would give results sufficiently accurate for ordinary purposes.

Professor Veal of Purdue University, a member of the Research Division of the Standards committee of the S. A. E., stated that that division had been working on such a basis of comparison for some time. He said that such apparatus as the accelerometer and chronometer gave precise and satisfactory results but they were too elaborate for every-day use. He thought that the work of the section along this line would be of assistance to the Standards committee. The matter then was referred to the Research committee of the section for report next meeting.

The new section of the S. A. E., the Mid-West section, organized recently in Chicago was introduced to the Hoosier section by Darwin S. Hatch of *Motor Age*, who outlined the purposes of the new section and stated that it would not incroach upon the territory of the Indiana branch.

The Research committee of the Indiana section then presented a report of a test made that afternoon for acceleration and speed of a Cole eight. With an eight-cylinder motor, 3½ in. by 4½ in., a Cole eight car (stock model except for cord tires), the acceleration on the speedway on high gear from 10 to 50 m.p.h. was made in 23.7 seconds. This was the average of two readings, one taken in one direction and one in the other. The speed test conducted in the same manner gave 64 m.p.h. These tests were made with the windshield in operation and the top up.

With the top lowered and windshield open the Cole eight made an average of 21.5 sec. in accelerating from 10 to 50 m.p.h. The maximum speed in this instance was the same as that of the previous one. The car was geared 4 to 1, had 34-in. diameter wheels, used aluminum alloy pistons with a clearance of 0.005. These are all stock specifications. However, castor oil was used as a lubricant. With the same carbureter adjustments the car gave an average of 2½ m.p.h. on high in the low-speed test. This was done with one bad cylinder caused by a seized piston.

Crawford's paper was read by Haynan of the Cole Motor Car Co., and was entitled, "The Characteristics of the Eight-Cylinder Engine." It appears in part on page 838 to 843.

Warm Discussion Follows

In the discussion of the paper W. G. Wall of the National Co. referred to Crawford's statement, "Since in any engine, the clearances are practically the same, the noise therefrom would be substantially the same per contact; the multiplication of the parts in operation will increase the noise in the same proportion as such multiplication occurs." Mr. Wall stated that if we multiply the parts of the same size and shape this would be true, but if they are not the same size and weight, it would not be true. He illustrated this with the suggestion of a boiler shop in which a sledge was being operated slowly with a heavy blow—this representing the small number of parts, and compared it with very rapid blows from a tack hammer, leaving it to be inferred that the rapid blows from a tack hammer would be less objectionable than the less frequent and louder ones from the sledge.

In reference to Crawford's remark that while vibratory force does exist, one usually is surprised in not being able to notice it when riding an eight-cylinder car, Mr. Wall stated that he did not know whether the eight has horizontal vibration, but the eight-cylinder cars that he had noticed reminded him of a large dog coming out of a pond and shaking it-

self. He thought Crawford was right as to the heat loss being less in the eight than in the twelve on account of the area, but the loss in the single cylinder engine is still less and there are things which compensate for this loss in the greater number of cylinders. One is able to keep the pistons cooler and to use smaller clearances with the small-bore motor and higher compression with a higher mean effective pressure.

In an eight the distance from the carbureter to each cylinder is less than in the six or twelve, but Wall expressed some doubt as to how much advantage this might give for all-around use. For slow speed work it is advantageous to have a small intake pipe and mix the gases there, but the high speed engine requires a larger intake pipe and with a large pipe better mixture is essential in the carbureter.

Gas Distribution Uneven on Twelve

Replying to this, Mr. Crawford stated that on the noise comparison he was not referring to the noise per tappet, but held that the multiplication of noise was more objectionable in the twelve than in the eight. So far as even torque and vibration are concerned, there was no appreciable difference between the twelves and the eight. He remarked that it was almost out of the question on the twelve to get an equal distribution of gas, although perhaps it could be done by complicated piping which, however, might give difficulties on account of friction.

Mr. Dorris of the Dorris Motor Car Co., stated that it was his belief that the engineers in this discussion were overlooking the buyer of the car. He thought they ought to glance over their repair shop list; that there were other items besides cylinders that were giving trouble.

Loomis Attacks Efficiency Argument

A. Loomis of the Packard company, who to an extent represented J. G. Vincent, took exception to some of Crawford's calculations in the matter of balance and in the matter of evenness of torque stated that the question resolved itself into the number of impulses per unit of distance traveled, which would give Packard 1375 as against 1030 for Cole or one-third more impulses with the stock gear ratio. In regard to the complication of water piping, he stated that this was the same on the twin-six as on the old Packard six. In considering the variation in volumetric efficiency, he stated that the Packard used this argument many years ago when building "one-lungers," in prophesizing that the two-cylinder never would replace the single-cylinder. In regard to the difficulty in getting the parts equal in weight, and the increase in this difficulty with the increase of the number of cylinders, Loomis admitted that this is difficult, but Packard is doing it on a commercial scale. Referring to Fig. 15 showing Crawford's suggested counter weights he stated that anything that increased the weight of the reciprocating parts increased the vibration and the increase of the counter weight was analogous to an increase in weight of the pendulum in a clock, which would slow it down.

Three Miles Not Low Enough

It is possible to find a lower limit to the desirable speed on high gear and the 3 miles suggested by Crawford could not be considered such a limit. Also there is always a limit to the frequency of the noise, but that limit is when it goes beyond the musical range. The twin-six frequency of noise is not high enough to be objectionable.

As to the accessibility of the steering gear, he stated that the Packard frame width was much less than that of the Cole, and contended there must be more difficulty in placing a steering gear with a 90-deg. motor than with a 60-deg. one. In conclusion, he said that performance is more than structural economy and that after an owner had driven twin-sixes no smaller number of cylinders would be satisfactory.

In refutation, Crawford stated that the 3-mile speed limit was set because it was expected every owner would get that and that he has obtained 1½ m.p.h. on high. He did not feel that engineers of twelve-cylinder cars have had proper experience with the eight, that the latter had been in the hands of owners for a year, and that when the twelves have been in owner's hands that time, difficulties will crop up that are not known of at present. He expects considerable variation in valve clearance in the twelve as there has been some in the eight and the difficulties from this point should upset the twelve more than the eight.

Mathematics of Noise

Alanson P. Brush, consulting engineer gave it as his belief that the twelves and the eights were equally good if kept in the best range of their adaptability; that for any speed range there is a critical cylinder diameter which will give best results, and that this factor is the one that should determine the number of cylinders. He believes that this critical diameter ordinarily is less than the 3½ in. mentioned.

In discussing the noise question, he developed the fact that if an engine be multiplied, all of its parts, exactly in proportion, *its kinetic energy will increase as the fifth power of the line dimensions*, that tappet impact decreases as the number of cylinders is increased. He repeated the statement that *quietness is continuity of noise* and that the impact is lighter on a twelve as the tappets are lighter and the energy of the blow is very much less. For the same power the *smaller valve parts of the eight and still smaller ones of the twelve should make upkeep actually less than for motors of a smaller number of cylinders*, if equally well designed and made.

The Placing of Accessories

Professor Veal stated that in his opinion it was harder to place accessories on the eight than on the twelve without lengthening the hood.

Mr. Heinze of the Heinze Electric Co., and formerly designer of the Northway engines, corroborated Brush's statement that there was a certain size of bore and stroke which gave highest thermal efficiency, but disagreed with Brush when he said that he thought this was greatest in a cylinder 4¼ by 5¼. This fact, however, he did not consider the most important consideration for the buyer, who is buying for the smoother running qualities of the eight and twelve. The smaller number of cylinders would give fewer parts but durability is more to be desired. Though the thermal efficiency was decreased with the increase in the number of cylinders, the public wanted even torque and less noise and that objectionable noise is heavy impact, so that *the more cylinders the less noise*. He said that engineers, whether they knew it or not, throughout the entire industry were striving toward the gas turbine. He thinks the limit is not reached in the twelve-cylinder.

Turbine Should Be Simple

Mr. Bull of the Cole engineering staff stated that it was not only the continuous torque of the gas turbine that made it desirable, it was its simplicity, consequently too many cylinders decreased simplicity. On frame width, he said the Cole size was the S. A. E. standard width and there should be no objection to a width already standardized.

Four Never Fully Developed

Mr. Crawford, in closing, stated that the four never had been developed in this country, that before it was brought to its highest point it was ditched for the six; that the two best motors for thermal efficiency and all-around efficiency ever built were the Sunbeam and Vauxhall, four-cylinder motors which, though they have different bore-stroke ratios have shown better efficiency than any others regardless of the number of cylinders.

Factory Miscellany

Weston-Mott Adds—Alterations which will cost at least $5,000 will be made at the plant of the Weston-Mott Co., Flint, Mich.

Work on Continental Plant Started—Work has been started in the new drop forge steel plant for the Continental Motor Mfg. Co., Muskegon, Mich. The structure will be 180 by 60 ft.

Gryphon Tire Buys Land—The Gryphon Rubber & Tire Corp., New York City, has acquired title to a plot of land, 250 by 103 ft., in the west side of Bailey Avenue, just north of 192d Street. The property also fronts on the tracks of the New York & Putnam Railroad.

Brewers to Make Tanks—American Brewers & Bottlers Specialty Co., Fourth and Windlake Avenues, Milwaukee, Wis., has entered the automobile field, and is specializing on gasoline tanks, its equipment being especially adapted to handle this class of work.

To Make Valve Grinder—The Just Specialty Co., Syracuse, was dissolved Oct. 15 and a new company styled Universal Equipment & Supply Co. formed to take its place. The new concern will manufacture and distribute a number of accessories including the Simplicity valve grinder formerly produced by the Just company.

Davis Co. Moves—Davis Manufacturing Co., Milwaukee, Wis., has abandoned its old plant at Fifteenth and Park Avenues and removed its entire equipment to its new plant at Fifty-seventh Avenue and Mitchell Street. The Davis company specializes on large motors for tractor purposes, although building to some extent motors for the automobile trade.

Crown Fender Plant in Ypsilanti—The city council has voted to turn over the Gaudy property to the Crown Fender Co., which has been negotiating with the Industrial Association for some time to locate here. It is provided that if no factory building is erected on the site within two years the Industrial Association is to reimburse the city or return the deed.

Federal Bridge Tests Tractors—The Federal Bridge Co., Waukesha, Wis., is now building tractors for several different companies, and each day the plant is the scene of a novel test. Two tractors with steering gears set run for hours continuously, without the attention of a driver. In this way the tractors are given a practical road test and are examined at intervals only to see that they are working satisfactorily.

To Make Springs—The Jenkins Vulcan Spring Co., St. Louis, Mo., has incorporated for $40,000, to make and deal in automobile leaf springs and accessories. The company has taken over the stock of the Jenkins Manufacturing Co., St. Louis, maker of the Vulcan spring. The officers of the new company are T. B. Jenkins, president; J. F. Jenkins, vice-president and secretary, and R. G. Zetrouer, treasurer and manager.

Dort Acquires Land—Land valued at $40,000, located west of the Dort Motor Car Co., Flint, Mich., has been acquired by J. Dallas Dort, president of the company, to provide for future expansion. The property comprises about 75,000 sq. ft. of ground. No buildings will be erected for the present time on the land, but it is expected that with the growing business the Dort company will start some building work early next year.

Ford Addition in St. Louis—The Ford Motor Co. will add a $300,000 building to its St. Louis branch, which will be ready by April 1. This building will duplicate the original building erected two years ago at Forest Park Boulevard and Sarah Street. The new building, fronting on Forest Park Boulevard, will cover a lot of 150 sq. ft. and will adjoin the site of the original building. It is to be fireproof, of brick and reinforced concrete construction.

Reo Truck Buys Bldg.—The Reo Motor Truck Co., Lansing, Mich., has purchased the large structure known as the Lyon Tabernacle, which has been used by Dr. Lyon. The truck business has been so exceptionally large that additional room had to be provided at once, although additions to the truck plant are under way. However, conditions have been such that much work has been going on on the grounds outside the plant and where neither the workmen nor the material and trucks were under shelter. It was principally to overcome this that the tabernacle building has been purchased.

Oct. 14.....Chicago Track Race.

The Week in the Industry

Westlake Joins Philadelphia Ajax-Grieb—W. A. Westlake has joined the Ajax-Grieb Rubber Co., Philadelphia, Pa.

Turner N. Y. Saxon Mgr.—H. C. Turner has been appointed manager of the Saxon Motor Car Co., New York City.

Hurd Heads Portland White—R. S. Hurd is the newly-appointed head of the White factory branch in Portland, Ore.

Cowan Sommer Office Mgr.—Harry Cowan has been appointed office manager of the Sommer Motor Co., Bucyrus, Ohio.

Jackson Empire Sales Head—W. E. Jackson has been appointed manager of the Indiana Empire Sales Co., Indianapolis, Ind.

Swap Service Mgr.—Frank Swap has been appointed service manager of the More Automobile Co., St. Louis, distributor for the Marmon.

Payne with Gibson—J. H. Payne has been appointed manager of the automobile department of the Gibson Automobile Co., Indianapolis, Ind.

Riley Heads K. C. Assn.—The Kansas City Motor Car Dealers Association has elected N. S. Riley, president; W. J. Brace, vice-president, and E. E. Peake, secretary and treasurer.

Marshall Buffalo Mgr.—G. J. Marshall is now manager of the Buffalo (N. Y.) office of the McGraw Tire & Rubber Co., East Palestine. He succeeds C. H. Connelly, who goes to Kansas City for the company.

Schwab and Beckler Leave Gemco—W. H. Schwab, formerly sales manager of the Gemco Mfg. Co., Milwaukee, and C. W. Beckler, formerly advertising manager of the same concern, have severed their connection with the Gemco company and become interested in the Auto Parts Mfg. Co., 528 Broadway, Milwaukee, Wis.

J. B. True, Jr., has been appointed director of sales of the Gemco Mfg. Co. Mr. True has had wide experience in merchandising and advertising and will handle the advertising as well as the sales department of the Gemco company.

—

Dealer

St. Louis Chevrolet Makes Lease—The Chevrolet Motor Car Co. of Missouri, St. Louis, recently incorporated, has leased the new two-story building forming the western tip of the Lindell Locust Cutoff, which it will use for office headquarters of the company.

Motor Men in New Roles

Join Sun Co.—J. L. Larkin and H. A. Minturn have become actively connected with the Sun Motor Car Co., this city, and take up their work at once.

Horton Appointed Mgr.—G. A. Horton has become manager of the automobile painting department of the Great Western Motor Car Exchange, St. Louis, Mo.

Corn Detroiter District Mgr.—B. J. Corn has been appointed district sales manager of the Detroiter Motor Car Co., Detroit, Mich. His territory covers Indiana and Kentucky.

Greig Joins Dunlap-Ward—C. N. Greig has joined the Dunlap-Ward Advertising Co. of Chicago and Detroit. Mr. Greig will be a vice-president and his headquarters will be at the Chicago office.

Fuess Returns to St. Louis Co.—E. J. Fuess who until recently had been connected with the Frye Motor Car Co., St. Louis, has rejoined that company and will manage its used car department.

White a Purchasing Agent—J. F. White has been appointed purchasing agent of the Anderson Forge & Machine Co., Detroit, Mich. He was formerly in a similar capacity with the Metal Products Co.

Bartlow Makes Change—V. A. Bartlow, formerly in charge of the Bosch service station at San Francisco, will assume charge of the Spokane service station for the Inland Empire at the Child, Day & Churchill Co.

White Leaves Pierce-Arrow—H. C. White, formerly superintendent of the assembling departments of the Pierce-Arrow Motor Car Co., has accepted the position of production engineer with the Curtiss Aeroplane Co., Buffalo, N. Y.

Jossman Columbia Truck Mgr.—Henry Jossman has been appointed sales manager of the Columbia Truck & Trailer Co., Pontiac, Mich., which recently moved to this city from Kalamazoo. Mr. Jossman was formerly connected with the Oakland Motor Car Co.

Thompson Makes Change—B. D. Thompson has been appointed production manager of the Curtiss Motor Co., Hammondsport, N. Y. Mr. Thompson was until recently machine-shop foreman of the National Twist Drill and Tool Co., Detroit, Mich.

Viot Joins Continental Motor—H. R. Viot has become director of purchases of the Continental Motor Mfg. Co., Detroit, Mich., and will look after the purchases for both the local and Muskegon plants. Mr. Viot was formerly purchasing agent for the Oakland Motor Car Co., Pontiac.

Beatty Goes to Providence.—S. M. Beatty has been transferred by the Goodyear Tire and Rubber Co. from the managership of the branch at Providence, R. I., to a position at the factory in the sales promotion department. He is succeeded by E. J. Smith, who had been manager of the branch at Hartford, Conn.

Eastman Philadelphia Packard Mgr.—Lee J. Eastman, who was assistant to E. B. Jackson when the latter was head of the company in Philadelphia, Pa., has been appointed manager of the Packard Motor Car Co., Philadelphia. Mr. Eastman had been acting manager of the Packard company there since Mr. Jackson's removal to New York City as president of the New York company.

Houghton, Dodge Rep., Resigns.—A. E. Houghton, district representative for Dodge Brothers in the Mountain States territory, with headquarters at 1608 Broadway, Denver, who has for three months been in charge of both the Denver and Omaha districts, has been succeeded in the Denver office by his assistant, C. A. Biggs. From now on Mr. Houghton will make his headquarters in Omaha exclusively and concentrate his work upon the larger territory handled from that point.

Buick Managers Form Oakland Co.—Robert H. Martin, manager of the Buick branch in Washington, D. C., for three years, has resigned. With A. G. Southworth, Brooklyn, and A. H. Salver, Buick manager in Pittsburgh, he has formed the Southern Oakland Co., and will be wholesale distributor of Oakland cars in Georgia, Alabama, Florida, Mississippi, Tennessee, South Carolina and western North Carolina. The officers of the company are A. G. Southworth, president; A. H. Salver, vice-president, and R. H. Martin, secretary-treasurer and general manager. The company's headquarters will be in Atlanta.

—

Dealer

Hartford Tire Pump to Add.—Plans for the factory and garage of the Hartford Auto Tire Pump Co., Hartford, Wis., have been revised to provide just double the space originally planned. The building will be of reinforced concrete and hollow tile, 55 by 88 ft., two-story and basement. Work is now under way.

VOL. XXXIII. NEW YORK—THURSDAY, NOVEMBER 11, 1915—CHICAGO NO. 20

The AUTOMOBILE

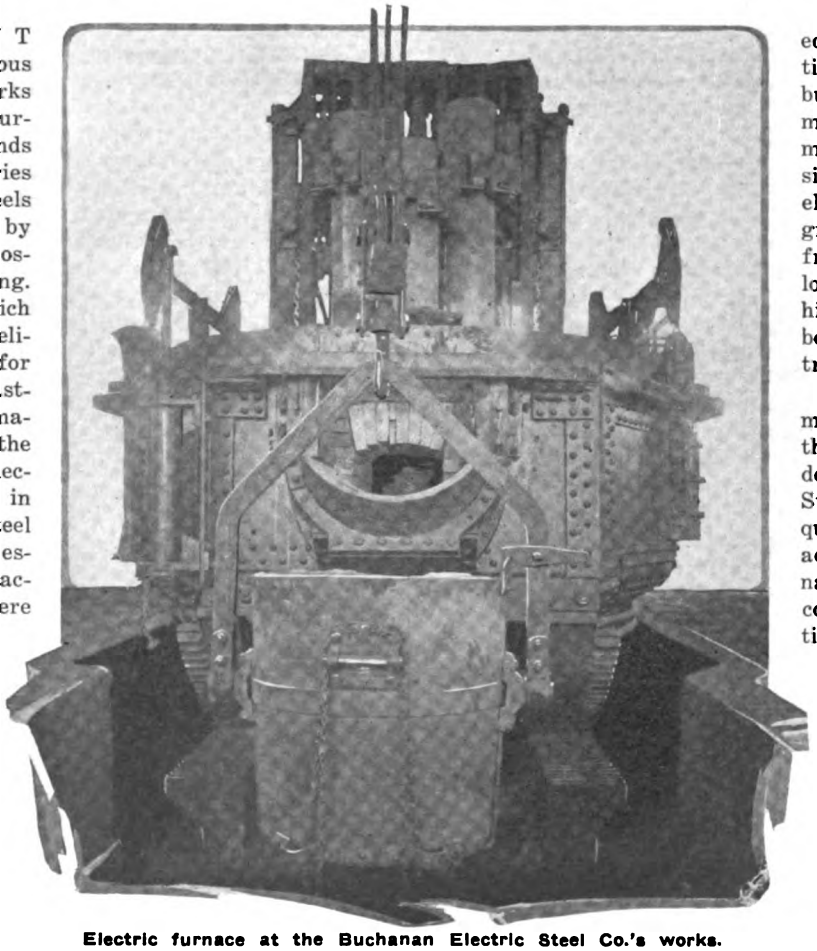
Electric Furnace Steels for Dynamic Stresses

Rapid Adoption of Improved Method Points to Coming General Use of Purer and Stronger Materials

By J. Edward Schipper

THROUGHOUT the country various iron and steel works are installing electric furnaces to meet the demands made in many industries for the high grade steels which can be produced by the super-refinement possible with electric heating. The demand for steel which must be the acme of reliability and the necessity for machined parts where wastage, due to impure material, shall be cut to the limit, has rendered the electric furnace a necessity in the manufacture of steel for many purposes, and especially, in the manufacture of automobiles where lightness and dynamic strength make the highest demand on materials.

Looking back ten years the development of the electric furnace and its application to steel refinement is marvelous. The few specimens of highly-refined steel then turned out in laboratories

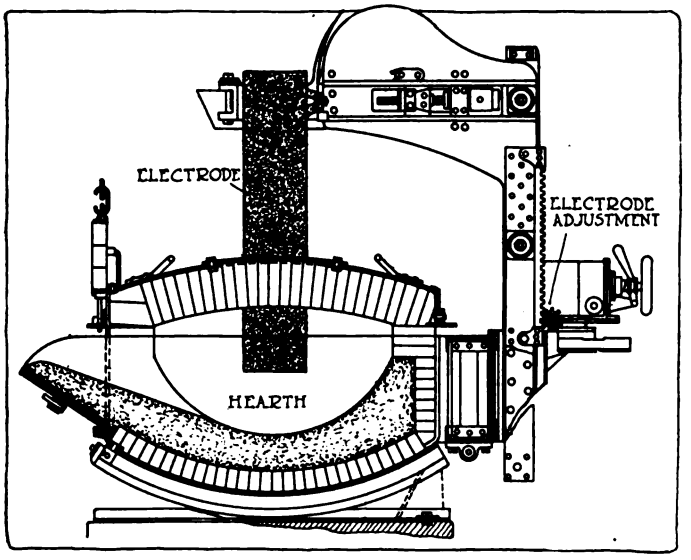


Electric furnace at the Buchanan Electric Steel Co.'s works. Note rack arrangement for tilting the furnace

equipped with this application of electric heat made but little impression on the minds of the practical steel men of the day. Gradually, since that time, the use of electric steels has been growing and now in cars from the highest to the lowest price are found high-duty parts which have been produced by the electric furnace method.

Although generally foremost in taking up and thoroughly utilizing a new development, the United States has not been as quick to avail itself of the advantages of electric furnace steel as have other countries. Authorities estimate that in the United States there are produced at present about 9000 tons per annum of electric alloy steels. In Germany there is produced per month as much as is turned out in the United States in a year.

At the beginning it must be understood that electric steels are more



Section through the Heroult furnace showing the construction of the hearth and mounting of the electrodes

expensive than those made by the open-hearth or other processes. Therefore, when electric steels are adopted, it must be because those who use them believe that the advantages offset the higher first cost of the material. While still a largely debated point it is undoubtedly true that most metallurgists are at the present time of the belief that not only is the electric steel worth the difference in price but that it results in a saving in many instances and furthermore a greater demand for its use would so reduce the price as to make the difference between it and open-hearth steel negligible.

Broadly speaking, the advantages of the electric furnace are largely centered about the facts that it is possible to confine the temperature variations within very narrow limits and that it is possible to carry out the high refining temperatures without exposing the molten metal to harmful gases. Metal made by this process, therefore, is nearer the complete state of refinement, containing a minimum amount of sulphur and phosphorus, being completely deoxidized and free from gases and nitrides.

The standard phosphorus and sulphur contents in open-hearth steel, unless special pig is used at an increased price, is 0.04 per cent. With special pig some mills will guarantee 0.035, the standard practice with the best manufacturers in electric steel is a guarantee of 0.02 sulphur and 0.015 phosphorus. The steel made by this process is, because of more absolute temperature control, more uniform. In the electric furnace the losses are confined to sulphur, oxides, gases and nitrides and all additions in the manufacture of alloy steel are made in the furnace and, as a result, these additions are more uniformly blended. In the open-hearth steel many of the alloys are added in the ladle or in the furnace only a few minutes before the heat is tapped. As a result the alloying substances do not have the same opportunity to become uniformly disposed through the material.

Five Great Advantages

In the electric furnace, on account of the closely maintained temperature, it is possible to cast the metal at nearer the desired temperature than is generally the case with the open-hearth. This gives greater uniformity in the ingots. To sum up it might be said that the direct advantages of electric furnace steel would be as follows:

Great uniformity, physically and chemically.

Higher degree of indestructibility in the thermal manipulation, *i.e.* forging or heat treatment after manufacture of the bars.

Due to freedom from oxides, gases, etc., the metal has a wider hardening range in heat treatment.

Owing to freedom from impurities it will have a longer life and be better qualified to resist dynamic stresses.

It will machine somewhat better than the average open-hearth and forge about the same, with the advantage of being more fool-proof in the heat manipulation.

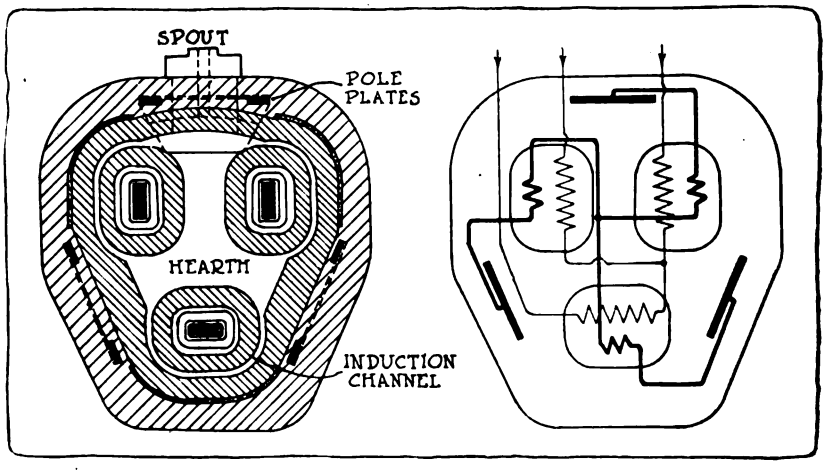
High Dynamic Strength

As to physical properties, an electric steel will be more uniform than in other processes because of the higher degree of purity. It is a fact, however, that these qualities will not greatly exceed those of the soundest part of an open-hearth ingot in which particular care has been paid to the process of manufacture. This of course refers to the static strength. But what is of extreme interest in automobile construction is dynamic strength, and it is for this reason that electric furnace steel should prove of great value to the automobile industry.

To offset the advantages many believe that under present conditions electric furnace steel will never reach the same quantity production as the open-hearth and therefore will always be more expensive. In the first place although steel is made in the electric furnace this alone is not a guarantee as to its quality; lack of widespread knowledge regarding the manufacture of electric steel is a handicap. Some engineers who have not closely followed progress in this work go so far as to state that the only good use to which electric furnace steel could be put by automobile manufacturers would be in case of faulty design where it would be necessary to replace a weak part by one of similar design but better material.

Weighing the advantages against the disadvantages it seems quite reasonable to expect that the use of electric furnace steel will grow rapidly in this country. The United States, with its population of 96,000,000 and a present production of electric steel of 9000 tons per annum, is not going to remain permanently at this stage in steel development while Germany, for instance, with its population of 56,000,000, has an annual output of electric steel of 108,000 tons. Although our output is small it is constantly growing, and in addition, America has been hitherto purchasing large quantities of imported alloy steels, but since the war has started these sources of supply have been interrupted and the result is that the electric furnace steel industry in this country is growing so rapidly that electric furnaces are continuously being added to the equipment of our steel manufacturers.

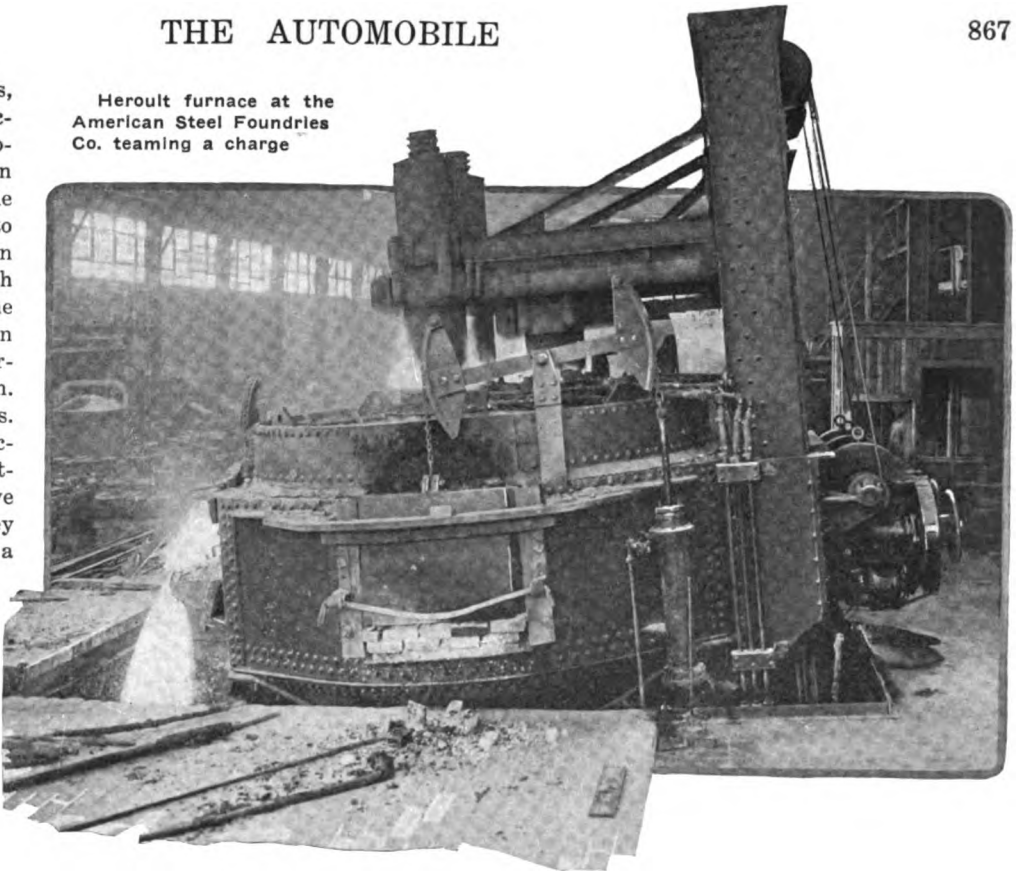
With the chief obstacle in the way of the use of large quantities of electric steel being the comparatively small produc-



Diagrammatic view of the Rochling-Rodenhauser furnace with layout of wiring connections

tion with resulting high prices, this turning toward America's factories for this kind of steel is going to have a beneficial effect on the entire industry and automobile manufacturers will not be slow to realize that there is oftentimes an actual saving in connection with electric steel. At the present time it costs approximately $45 per ton more to manufacture electric furnace steel than it does open-hearth.

This is due to several causes. The most successful types of electric furnaces are covered by patents and the steel companies have to pay a royalty for every ton they make. Again, electricity as a heating unit is more expensive than coal or gas which are employed in the open-hearth. The high cost of the electrodes burnt away in the manufacture of steel is another contributing cause and, finally, the smaller heats, because electric furnace steel is made in 6- to 20-ton furnaces whereas open-hearth alloy steels are made in 50- to 65-ton furnaces. Another point often brought up is that in order to keep down the carbon range, more expensive alloys have to be used than in the open-hearth, that is to say, alloying substances of the carbonless variety which, as a rule, cost considerably more.



Heroult furnace at the American Steel Foundries Co. teaming a charge

Due to the peculiar conditions which obtain in the working of alloy steels, better results are obained in some instances by charging cold material directly into the electric furnace. In other steels better results are obtained by melting in the open-hearth and then charging the hot metal into the electric furnace for ultimate refining and for adding the alloying substances.

For Automobile Work

In automobile work the majority of the materials used do not have to be of very close analysis to give desirable service, but there are a few parts which are of such great importance that the finest possible material is not too good for use. By using electric furnace steels on such parts a great amount of trouble is avoided because electric furnace steel, due to its high temperature of refinement and superior chemical composition is closer grained and has higher physical qualities than the average open-hearth steel.

Furthermore, the percentage of wasted parts where considerable machining is done is much reduced by its use and this reduction is such a potent factor where the ratio of machine cost to material cost is high that the initial difference in the price of the material is equalized.

In the use of ordinary alloy open-hearth steels a large number of highly-machined parts might often necessarily have to be thrown aside due to the encountering of a spot of impurity or some slight subcutaneous defect. The loss in time of the machine and the workman would be far more costly than the difference in price between the two steels and, at the same time, owing to the better physical qualities of the electric steel, a better part would have been made. Discarding finished pieces where expensive forges, dies, milling machines, drills, etc., have been employed in the various stages of the work together with high-priced machinists, is a serious wastage.

It is true that the mere fact that steel is made in the electric furnace is not a guarantee as to its quality, but with steel properly made in the electric furnace, using the same methods and care that are customary in the small mills, or in other words, quality work as contrasted with solely quantity work, electric furnace steel will be far superior to the ordinary open-hearth product because it will be made in small heats and small ingots which means a safeguard against segregration. Electric furnace steel is freer from sulphite of manganese and also slag, which is particularly harmful in case-hardened parts. The presence of slag is one of the principal reasons for the pitting and spoiling of case-hardened parts.

Another advantage of electric steels is that being handled in small units it will ordinarily receive much more careful inspection, so that surface defects and pipes will be detected.

An interesting fact concerning tungsten magnet steel used in the permanent magnets of magnetos is that when made in the electric furnace it has a higher retentivity than when made by any other method. Probably the close structure of the molecular arrangement is of influence.

History of Electric Furnace

The electric furnace is not a new development, although its practical application is one of the phases of modern industry. Probably the first electric heat machines were the mechanisms and apparatus employed by Davy, who in the year 1810 produced heat in the electrolysis of aluminum oxide. His apparatus consisted of a platinum plate connected with one pole of a thermopile of 1000 plates, the other pole being connected to an iron wire. The iron wire projected into a layer of clay carried by the platinum plate which was in connection with the other pole. When the current was switched on the iron wire became white hot and melted where it was in contact with the clay.

Five years later Pepys welded an iron wire by heating it with an electric furnace and in 1843 it was first suggested by A. Wall that electric current be used in treating pig iron in the converter. In 1853 there was a French patent granted to Pichon for the first electro-thermic furnace. This was the first direct commercial application of electric current to furnace work and made use of the electric arc.

A great forward impulse was given to the possibilities of electric furnace steels when William von Siemen patented his furnaces in the years 1878 and 1879. Siemen's furnaces varied in design. The first was a crucible surrounded by a metallic case through the bottom of which projected one pole of an electric circuit. On this was mounted a platinum electrode, the second electrode entered through the cover of the furnace and in order to preserve it and give it the longest possible life it was cooled by water, a practice which still obtains. There was a heat-protecting cover for the furnace and the crucible was insulated to prevent radiation. Another furnace used by Siemen was very similar to that of Pichon.

Siemen's Furnace a Pioneer

With the Siemen furnace it was possible to melt 22 lb. of steel an hour and with it he could even fuse metals of such high melting point as platinum, having succeeded in liquefying 8.8 lb. of the latter in 15 min. The only reason that the Siemen furnace was not an immediately commercial success was due to the high cost of electric current in those days. The present types of successful furnace such as those of Stassano, Heroult, Kjellin and Taussig appeared after 1890 and particularly between the years of 1898 and 1910. From that time it has been a matter of refinement of the constructions originated by these men, until to-day it seems as if we were on the verge of a rapid adoption of the electric furnace by steel makers generally.

One of the objections which some have urged against the electric furnace is that it requires the services of high-priced men to operate them. Some have claimed that the workmen in charge of detail labor on these machines must be electrical engineers but the growing tendency toward the use of automatic control is eliminating the necessity for men with a highly theoretical electrical education. The objection of one of the leading metallurgists in the automobile industry to the electric furnace is that the time and high degree of skill necessary to produce the improved qualities in material seems out of proportion to the advantages gained except for special cases. It is quite true that the open hearth furnace properly manipulated can keep the two impurities, oxygen and sulphur within such low limits that the material will perfectly satisfy the requirements for the great majority of constructions. Given the same amount of skill in both cases the electric furnace will doubtlessly remove more oxygen and sulphur from steel than can the open hearth.

Three Broad Classes of Furnace

It should not hold true that more expensive materials can enter into the construction of a high-priced car than a low priced one, as there need not be any relationship between the selling price of a car and the quality of the material which enters into it. The same relative proportions of very high grade steel to ordinary constructive material can hold true regardless of price, and hence the additional skill required in manipulating the furnace would not seem to limit the use of the steel to only high-priced cars.

Electric furnaces in general use can be classified under the broad heads of the arc furnace, the induction furnace and the shaft furnace. All three are based on well known electrical phenomena and in the fundamentals, are simple. In the arc furnace the entire theory and construction depend on the fact that if the ends of two current-carrying wires are brought together so as to complete the circuit and are then separated, the current will not be interrupted, but there will appear a small highly-luminous flame bridging the gap between the two ends of the wires. This separation of the electric current is what is known as drawing the arc. The theory of the arc is that at the instant of separation of the wires a great rise of resistance takes place at the point of separation and, since resistance causes heat, a quick rise in temperature also takes place. Under the influence of this heating the metal evaporates at the points of contact. If the separation should be increased the distance between the ends of the wires becomes filled with metallic gases which transfer the current across the gap. Since these gases are of high resistance a continuous glow is maintained.

The ends of the two wires correspond with the electrodes, and the gasification of these electrodes consumes them so that were the correct distance between them not continuously maintained the arc would be broken on account of the evaporation which would open the gap too far by the destruction of the electrodes. The ordinary arc lamp is a good illustration of the arc theory. The electrodes used in the arc lamp are usually ordinary pure carbon. The arcs in electric furnaces are made in a very similar way. The electrodes commonly employed are carbons, as a very high temperature is maintained with this sort of gap. The reason for this is that in carbon the greatest resistive conducting material is found and the gasification is at about 3500 deg. C. This is the arc temperature used with iron and steel when carbon electrodes are employed.

The different types of furnace made under the general head of the arc classification vary with the different manufacturers. Some of the principal furnaces made using the arc theory as the basis of their design are the Heroult, Stassano and Girod.

Induction Type Often Used

The next main classification of electric furnaces is the induction type. It is a known fact that when an electric current is passing through an insulated coil it is continually generating lines of force. If the current through the coil is alternating, the lines of force are also alternating and any electrical conductor in the path of these alternating lines of force will have a current induced in it. The strength of this current induced would be proportional to the number of lines of force cut by the conductor. In regulating the strength of this current there are two or three fundamental facts which

STEEL DIRECT FROM ORE	3,000 K.W. HOURS
PIG IRON DIRECT FROM ORE	2,000 K.W. HOURS
STEEL FROM COLD PIG IRON	1,500 K.W. HOURS
STEEL FROM FLUID PIG IRON	1,000-1,200 K.W. HOURS
STEEL FROM COLD PIG IRON AND COLD SCRAP	900-1,300 K.W. HOURS
STEEL FROM MOLTEN PIG IRON AND COLD SCRAP	600-1,000 K.W. HOURS
STEEL FROM COLD SCRAP	600-900 K.W. HOURS

Chart of kilowatt-hours estimated to carry out work by electric furnace methods

govern design. In the first place the voltage of the induced or secondary current is proportional to the number of turns of wire. Secondly, the strength of the current is inversely proportional to the voltage and inversely proportional to the number of turns.

This latter fact outlines the basic problem of induction furnaces which are really special transformer units. Every induction furnace has first its iron core and yoke surrounded by a primary winding and a secondary winding much in the same manner as a magneto except that in the case of the furnace this winding is composed either entirely of, or for the most part, of the bath itself. This allows of a subclassification of induction furnaces; those in which the high-tension or secondary winding is composed entirely of the bath, such as the simple induction furnaces; or where the bath forms part of the secondary winding with an additional winding made of copper to aid in the heating, as in the combination furnaces. The induction furnaces which are perhaps better known than any others in this country are the following: Kjellin, Rochling-Rodenhauser, and Snyder.

The electric shaft furnace is the resultant of the attempt to replace the fuel in the blast furnace by electric heat. In other words, it is merely a variation of the blast furnace with electric instead of flame heat.

Heroult Furnace Is Popular

While space does not permit to go into a detailed description of the various furnaces it might be interesting to mention the Heroult furnace as probably that in most common use. There are in this country at the present time about forty-two electric furnaces, nineteen of these are of the Heroult type, six of the Girod type, six induction furnaces, four Stassano, five Snyder and two miscellaneous. Of this number approximately 75 per cent are located in the Eastern States, and the capacities range from ¼ of a ton to 20 tons.

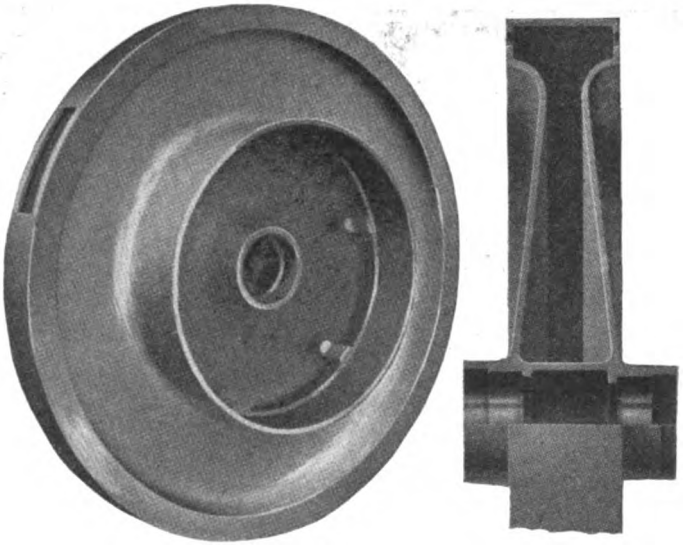
The accompanying illustrations show a furnace of the Heroult design which was recently installed in one of the plants of the American Steel Foundries. Referring to the illustrations at the tops of pages 866 and 867, this furnace, which is a 6-ton basic design, is shown in such a way that the three electrodes may be observed at the center. As stated, the Heroult furnace is of the arc type and this particular installation operates on a three-phase alternating current of 100 volts. The threaded projections at the ends of the electrodes are to allow new electrodes to be screwed on to the old ones thus eliminating any waste.

The electric current is stepped down from 11,000 volts to 100 volts in the transformer house and connections to the electrodes are made by heavy copper bars. Both the annular copper castings which hold the electrodes and the bushings where the electrodes pass through the roof of the furnace are water cooled. The path of the current is through the metal from one electrode to the other, the arc producing an intense heat which reduces the metal.

The electrodes are supported from the framework at the rear and each electrode is raised or lowered by an electric motor at the base of this framework. On the wall of the transformer house may be seen a delicate regulating mechanism which controls these motors and automatically keep the ends of the electrodes a short distance from the surface of the metal. Thus any surges of metal within the furnace will immediately react on the regulating mechanism and the electrodes will be kept at the proper distance from the molten metal.

Furnace Tilted by Rack

The furnace has a bowl-shaped bottom on which are two parallel curved castings with gear teeth, similar to a rack. By means of an electric motor, the furnace can be tilted or rolled on these plates to the angle required in drawing off heat. The tilting mechanism consists of a 40-hp. motor, driving direct on a large gear. A connecting-rod from the gear to the base of the furnace transmits the power for tilting and also makes the tilting mechanism "fool proof," for when the connecting-rod reaches its highest position, the gear in continuing its revolution will draw the furnace back to its normal position. The pit under the furnace is about 10 ft. deep and as the roller plates rest on pedestals, there is ample room for workmen to clean out slag, etc.



Single and double-disk wheels made from electric furnace castings

Movable Steel Heat Table

A very ingenious feature designed especially for this furnace by the plant engineering department of the American Steel Foundries, is the movable table in front of the tap hole. This table is covered with fire brick and is mounted on four wheels. When ready to take a heat from the furnace, this platform is rolled back on its track and the ladle is dropped into the put as usual. When the ladle is removed after drawing off the heat, the table is quickly pushed back so that the men can work on the tap hole with ease. In former furnace installations this has been a source of more or less trouble, as a few boards or a cover had to be placed over the hole, which was unsatisfactory and more or less dangerous. The new arrangement is very satisfactory.

The furnace has two charging doors, one on either side. These, together with the tap door, are operated by air. The furnace roof of course is of brick and it is inclosed in a steel ring in such a manner that the whole roof can be lifted off with a crane and a new one put in its place when necessary.

This furnace is typical of the very latest practice in electric furnace installations and is able to meet the most exacting demands in steel castings.

Physical Characteristics of Sample Electric Chrome-Nickel Steels

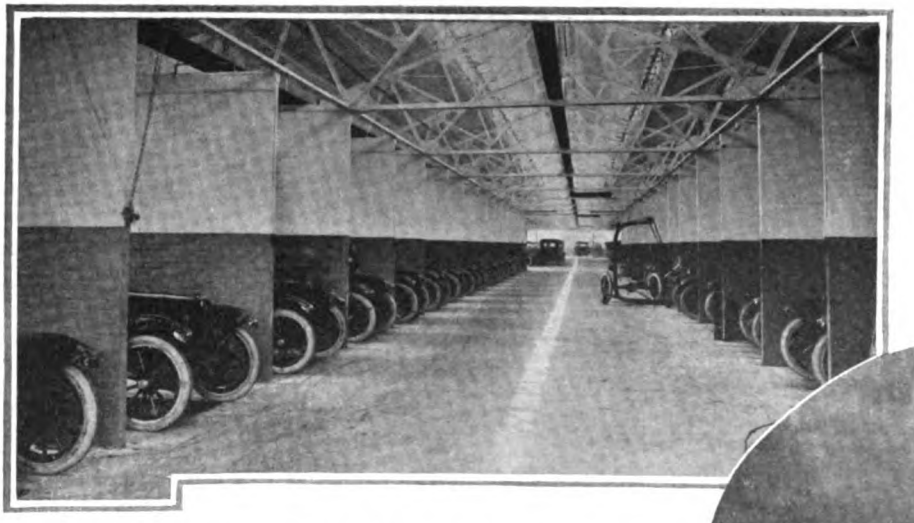
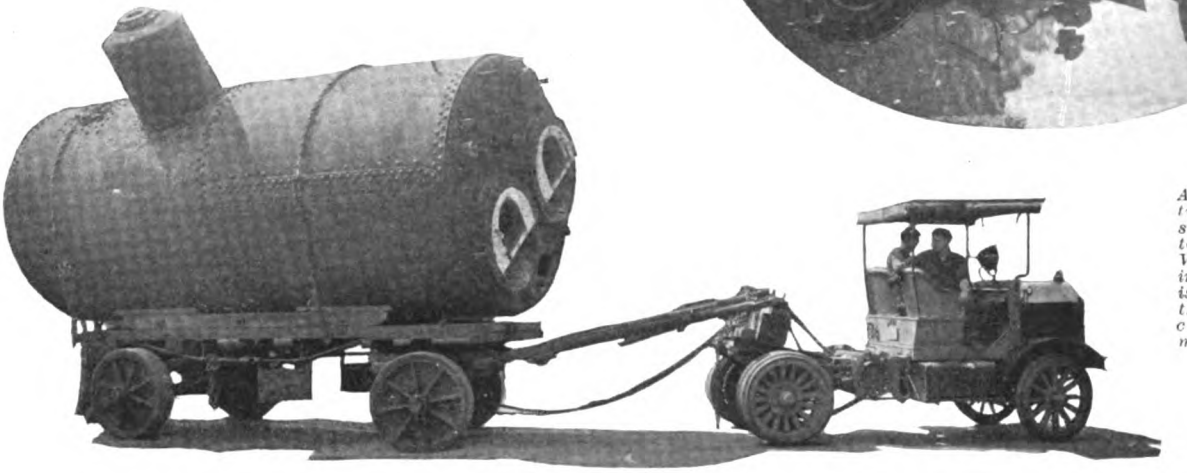
Feats and Features from Field and Factory

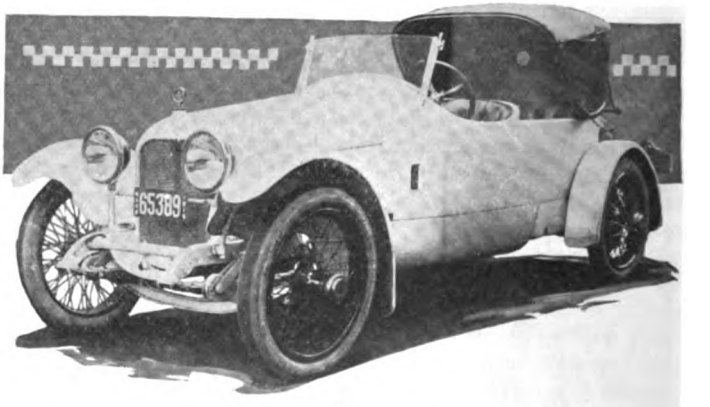


Above is illustrated a testing shed of the Dodge Bros. plant, Detroit, Mich. Solid brick partitions which are practically soundproof form a series of stalls on each side of the center aisle. After the car has been tested on the track it is run in one of these stalls and the tester is able to detect and remedy the faintest knock

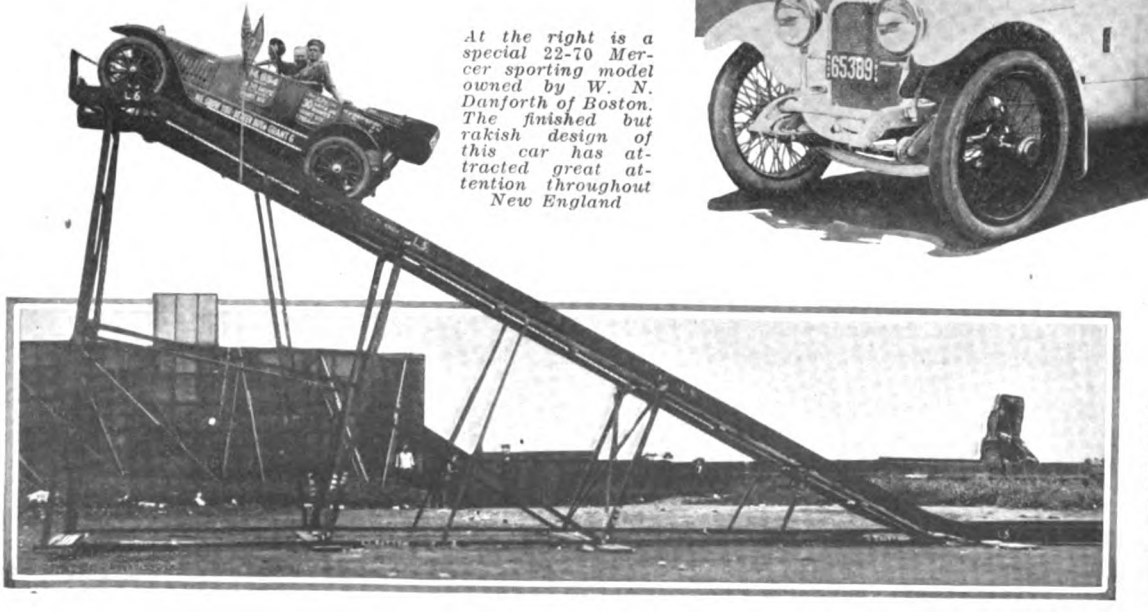
Above is a National twelve fording a stream on a field test at the base of Wild Cat Mountain in Tennessee. This is made possible by the high location of carbureter and magneto in the V of the motor



Above is illustrated a Knox tractor which recently moved a 33-ton boiler on an 8-ton wagon from a power plant at Holmsburg, Pa., to the Philadelphia city power plant at Fairmount Park. The total load hauled was 41 tons, although the tractor is rated at 5 to 15 tons capacity



At the right is a special 22-70 Mercer sporting model owned by W. N. Danforth of Boston. The finished but rakish design of this car has attracted great attention throughout New England



At the left is illustrated a test of a Grant six on a 50 per cent grade made at the Chicago sales rooms. The car starts on a runway 24 ft. from the bottom of the incline and then climbs 36 ft. on an 18-ft. standard

Piston Practice*

Present Day Design With Special Reference To Aluminum Alloy

By James E. Diamond

WHILE the aluminum alloy piston has been widely discussed, orally and otherwise, in recent months, rather more emphasis has been placed on the advantages of this type than on its design. The question of piston design in general offers profitable study and I believe its consideration at this time to be particularly appropriate for two reasons:

In the first place, not infrequently in recent months, the hope has been expressed that piston design might be standardized. Possibly, therefore, a setting forth of such differences of opinion relative to piston design as exist among engineers may offer a starting place for a movement looking toward the realization of this agreeable state of affairs. In the second place, such consideration is undoubtedly appropriate on account of the pre-eminence of the Lynite piston made by the Cothias process, a detail of which method involves the use of permanent molds, and to permit the utilization of which process, engineers must occasionally concede minor details of design. Further, it would seem the important position assumed by this new type of piston should warrant a consideration of certain limitations of the Cothias process should any move toward standardized design appear likely of success.

*A paper presented at the November meeting of the Detroit Section of the Society of Automobile Engineers.

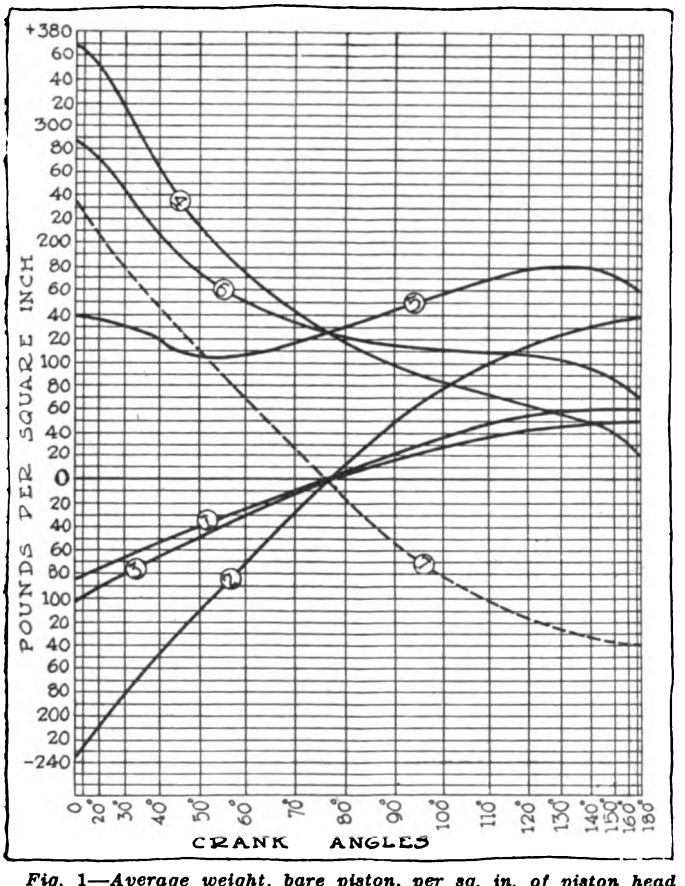


Fig. 1—Average weight, bare piston, per sq. in. of piston head area for Lynite Cothias Process Piston = .0875 lb.
Average weight, bare piston, per sq. in. of piston head area for ordinary cast iron piston = .240 lb.
Various inertia curves for motor with 6-in. stroke, at piston speeds of 1000 and 1500 ft. per minute. These curves for bare piston masses:

(2)—Same for cast iron piston at same r.p.m.
(3)—Same for cast iron piston at 2000 r.p.m.
(4)—Assumed expansion gas pressure curve.
(5)—Curves numbers (2) and (4) combined, showing actual piston force.
(6)—Curves numbers (1) and (4) combined, showing actual piston force.
(7)—Combined inertia and exhaust gas pressure curves, iron piston, 3000 r.p.m.

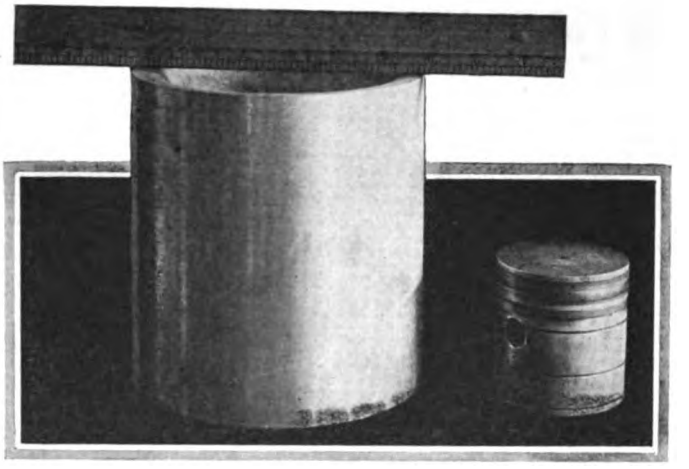

Fig. 2—By way of contrast

However, before entering into an extended consideration of design I venture to comment briefly on some points of superiority of the aluminum alloy piston, first, outlining its advantages generally, then, pointing out wherein the piston made by the process to which allusion has just been made is so much superior to the sand cast one.

Advantages of Alloy Piston

The weight of the aluminum alloy piston is, roughly speaking, but one-third that of a cast iron one of the same design. Therein, of course, lies its fundamental advantage. It naturally immediately follows that the inertia forces attributable to the purely reciprocating mass, by the use of the former, are reduced approximately 60 per cent since the force of inertia is a function of mass and acceleration. It will be recalled that the magnitude of these forces increases as the square of the piston speed, a fact which the advent of the high-speed, long-stroke motor has emphasized as it never before has been. Therefore, there is little need of dwelling on the significance of the reduction of the reciprocating mass, other than to note the marked reduction in the magnitude of the unbalanced forces, the fluctuation of which latter, is the major cause of motor vibration. It follows that the smaller these vibratory forces, the more likelihood that the motor will be able to absorb them within itself, no matter the direction in which acting. Possibly, too, in the past there has been a tendency to underestimate the effect of inertia forces on bearing pressures, but this seems now fully recognized. Quite conceivably, in motors of the type just mentioned, these inertia forces may produce bearing pressures quite comparable with those occasioned by the actual working forces in the motor. Bearing life is a decidedly practical consideration, and to say that decreased bearing pressure will result in increased bearing life is axiomatic.

The incidental advantages of this type of piston are several. The co-efficient of friction of the Lynite piston alloy is but half that of iron. This is significant in two or three ways. In the first place, there must be a gain, however slight, in mechanical efficiency in the motor, and it is these slight gains that the engineer to-day is seeking. Also, the piston side pressure may be increased without unfavorable results. This has a bearing on a type of piston, the design

of which will be later discussed, in which there is some reduction in the bearing area.

The much greater thermal conductivity of the aluminum piston alloy is likewise a factor of no little importance. This greater conductivity variously determined as from ten to fourteen times that of iron, reflects itself in a marked decrease in the amount of carbon deposited on the piston head. In fact under favorable lubricating conditions, there may be a total absence of carbon.

Advantage may be taken of this thermal property in increasing, if desired, in motors of the smaller bores, the compression beyond the point at which preignition would invariably occur with iron pistons. In fact, in one or two cases such advantage has been taken.

Characteristics of Cothias Piston

The piston made by the Cothias process, is superior to the sand cast one in every respect. The point of superiority in which its pre-eminence is most marked—and of the greatest practical worth—has to do with the quality, hardness. The Lynite piston alloy which has rather exceptional qualities even when cast in sand, acquires a hardness fully 25 per cent greater in this process. In fact, its hardness falls not far short of that of the average piston iron. At the same time, it is enough softer than the iron or semi-steel of the cylinder, that in the event of piston seizure, it is the cylinder, and not the piston that does the scoring.

Incidental to this process, additional strength is imparted to the metal, this increase ranging from 20 to 30 per cent. However, this gain in strength is quite secondary in importance to the gain in hardness just noted. I might add, however, that in one particular case, the difference between the sand cast and the piston made by this method, both pistons of identical design, was the difference between failure and success.

Quite aside from the engineering aspects of the matter, this Cothias process piston should, and does, commend itself to the manufacturer. Its advantages from the standpoint of production are quite obvious. As the pistons come from the mold practically exactly round, a finish of but 1/32 in. on a side is all that is required, not more than may be removed by two grinding operations, a rough and a finish. The wristpin holes are also cored, possibly saving one operation, or, if not, at least cutting the machining time in half. Considering now the sand casting this requires rather a liberal amount of excess stock for finish and the wristpin holes are but rarely cored. The foundry must be paid, and quite properly, for this excess metal, and in addition to this now unnecessary expense further expense must be incurred by the extra operations required to remove this same excess stock. As a basis of comparison, I have weighed rough sand castings and unfinished castings of the type being described of similar design, and find the former to weigh between 30 and 40 per cent more. To cite one specific case, the sand casting weighed 1¾ lb., the other but 1¼ lb., a saving of ½ lb. of metal per piston.

Regarding machining, a moment back, grinding was mentioned, such reference being made advisedly, since no difficulty is encountered in grinding the Lynite Cothias process piston, due to the acquired hardness of the metal. Kerosene seems to be the best grinding or cutting compound. As a matter of fact, however, I should judge that the majority of manufacturers prefer to machine their pistons on rapid lathes. With this procedure, fully as large production is being attained, and at less cost, it is stated. In a few instances, these pistons are being burnished, the alloy taking a high polish. This practice has much to commend it.

Difficulties with the Alloy Piston

A consideration of the difficulties experienced with the aluminum alloy piston should by no means be neglected. Fortunately, this consideration may be brief, since the troubles anticipated by most engineers a year ago on account of the relatively greater expansion of aluminum than iron, have not materialized. I would like to mention here that the co-efficient of expansion for iron is 0.0000119 and aluminum 0.000023 per deg. Fahrenheit, about one to two, but the difference is not as significant as might seem to be the case, since the greater thermal conductivity of the aluminum alloy is a factor which plays a part in the actual expansion of the piston.

It is not to be denied that trouble has been experienced in individual cases, but in practically every instance it has been possible to eliminate such trouble. The difficulties have, in the main, been two. Piston slap has been one of them, although as a matter of fact, very little has been said about slap in the last three or four months. The other has had to do with the pumping of oil in high-speed motors, while running at low speeds. This pumping naturally signifies, if nothing else, a larger consumption of oil with the incidental consequence of smoky exhaust and occasional sooty plugs, though these two do not necessarily follow. However, this trouble is by no means confined to the aluminum alloy piston, iron pistons under similar conditions having been known to pump oil; however, the condition is aggravated with the alloy piston, due to the fact that practically none of the clearance allowed for expansion when turning over at high speed has been taken up by the piston body, while on the other hand, with the motor throttled down, the vacuum created by the intake stroke, results in a greatly increased suction in the space between piston and cylinder. Various means of overcoming slap and oil pumping will be mentioned later in the paper.

Incidentally, brief scrutiny of the prints that it has been

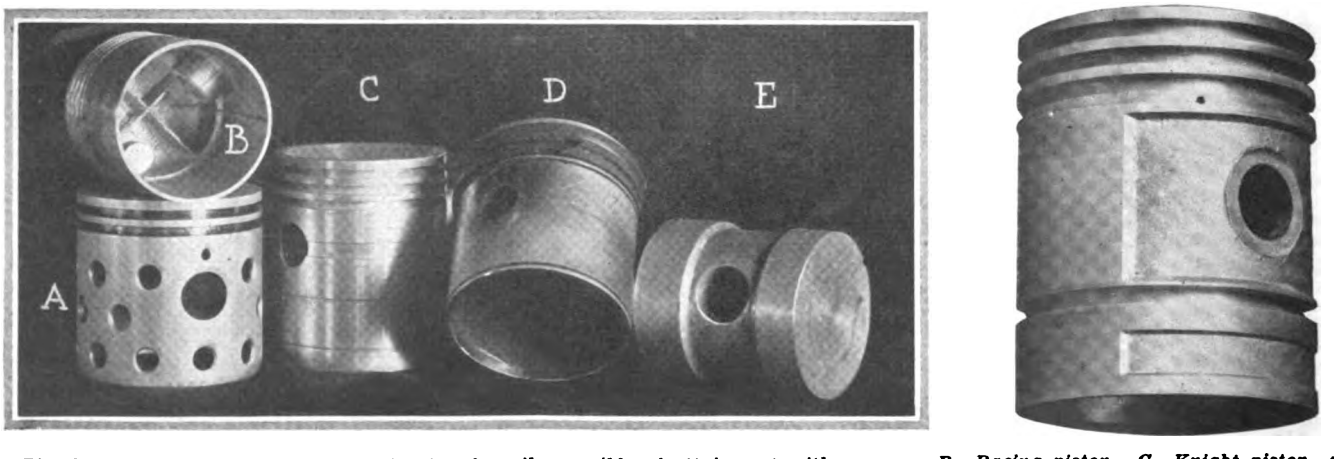

Fig. 3—A—Cothias process piston, showing fine ribs possible of attainment with process. B—Racing piston. C—Knight piston—note concave head. D—Piston, 490-hr. run, block test, at speed of 1200-1300 r.p.m., equivalent in mileage 17,000. Wear about 0.00025. E—English hourglass piston. On right—Northway piston.

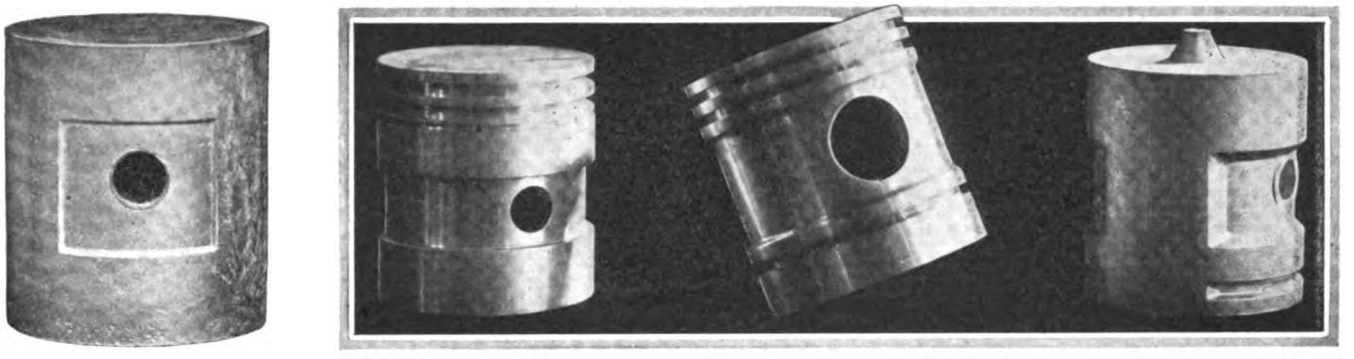

Fig. 4—Left and right—Northway piston. Center—King piston. Note wiping ring is employed

my pleasure to receive, would force home to designers generally the advantage of standardized design. Closer scrutiny would seem to show the possibility of reconciling these various designs. The prints submitted show pistons of fifteen or sixteen diameters, the latter ranging from 2½ to 5⅛ in. and while I feel entirely safe in saying that no two for the same bore motor are interchangeable, at the same time, in many cases, the differences are slight and might easily be compromised. Some of the variations noted will be mentioned. For instance, only one print showing a 2⅝ in. piston was submitted. The head of this piston showed a thickness of 5/32 in.; on the other hand, a piston 3¾ in. diameter calls for a head thickness of but ⅛ in. Similarly, another 3 in. piston calls for a head thickness of 3/16 in., the same as another 4¼ in. piston. There is the same diversity in the size of the wristpin. A small piston has a large one, and vice versa. Some designs make provision for oil drainage. In others there would seem to be none whatever. Another point of variation is in the width of ring used. As frequently as not, the smaller piston has a wider ring. However, tabulation has shown the ring with a width of 3/16 in. to be the most commonly used one for pistons with diameters between 3 and 4 in. In passing, possibly 90 per cent of the blue prints to which reference is being made, show pistons for motors with bores lying within these limits, and the most recently received prints show a decided trend toward the smaller bores. It is interesting to note that this independently made tabulation checks up exactly with the proposed S. A. E. standard for piston ring widths, and which will later be mentioned. The use of three rings seems to be the standard practice. In one or two instances, four rings are employed at the upper end of the piston; in three or four, but two rings. Several designs show the employment of a so-called wiping ring at the lower end of the piston, three rings being used at the upper end. In one case, provision is made for but two rings.

Piston Length Variation

Another point of great variation is that of piston length. A few, in my opinion, fortunately a very few, have a length no greater than the diameter. In one case, the length is less than the diameter. On the other hand, a few pistons have a length nearly one and one-half times the diameter. To mention the dimensions of a piston used in a recently announced model its diameter is 4⅝ in., its length 6 1/16 in., or the length in terms of the diameter is one and thirty-nine-one hundredths (1.39) the diameter. In general, the piston length has been found to vary from one and one-fifth (1.2) to one and three-tenths (1.3) the diameter.

Determination of Head Thickness

Let us consider from the standpoint of theory the conventionally designed piston. I characterize as the piston of conventional design the one employing rings, regardless of number, at the upper or head end only. This arrangement is quite the most common. Most treatises on design resort to the formula of Grashof in the determination of thickness of head, considering the piston head as a circular plate.

Grashof's formula is of the following form:

$$\text{Thickness } t = D\sqrt{\frac{P_m}{6S_p}}$$

Where D equals the diameter in inches, which may be taken as the bore, P_m equals the maximum pressure per square inch and S_p equals the allowable working stress in tension in the metal.

Merriman in his Mechanics of Materials derives a formula of the form:

$$\text{Thickness } t = \frac{3D}{4}\sqrt{\frac{P_m}{2S_p}}$$

For cast iron, S_p with both formulae is given as 3000 lb.

Formula Inapplicable

With one qualification, these formulae, assuming a maximum explosion pressure of 450 or even 400 lb. per square inch, give head thicknesses much greater than is current practice as shown by these prints. Of course it is possible, provided either of these formulæ has been used, that much higher allowable tensile stresses have been assumed than named as safe by the authors. I am inclined to think that most designers in calculating head thicknesses, have considered the problem as simply one in shear, and which I believe is an entirely safe procedure for pistons of diameters no larger than those of automobile engines.

With an assumed maximum explosion pressure of 450 lb. per square inch, and a figure that should provide for the exceptional condition, and an allowable unit tensile stress of 1500 lb.

F being the unsupported diameter of head

$$\text{Thickness } t = \frac{F}{13} \text{ approximately.}$$

Investigation has disclosed the unsupported diameter of head to range between eight-tenths (0.8) and eighty-five hundredths (0.85) the piston diameter, from which, taking the mean, it at once follows that

$$\text{Thickness } t = \frac{D}{16} \text{ approximately.}$$

I will anticipate the question that will possibly be raised, relative to the large factor of safety employed. As is well known, there is a tendency with all metals and alloys to lose a portion of their strength during actual subjection to continued high temperature. As a matter of fact certain aluminum alloys become very brittle under such conditions. The question of immutability under long continued high temperature is a most important one. While we believe we have developed an alloy of a nature peculiarly resistant in this respect, at the same time caution should be the keynote. It should be borne in mind that the melting points of aluminum alloys are much closer to the operating temperatures in motors than is the melting point of cast iron. The slight increase in head thickness given with the factor of safety used, will increase the weight of the piston only very slightly.

From the standpoint of thermal conductivity, a deep rib

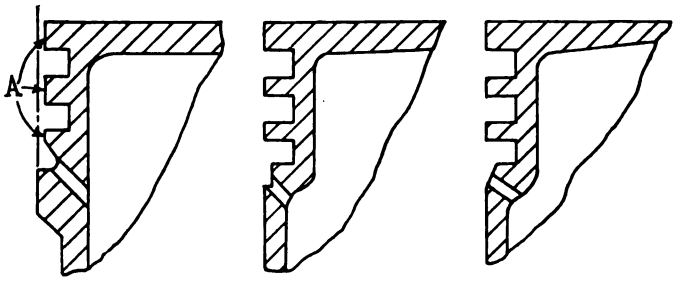

Fig. 5—Right and center—Provision for oil return. Two methods commonly employed shown. Left—Detail of King hourglass type piston showing ingenious oil drainage provision. Note bottom ring is backed by land of full depth, there being no sacrifice of support as in the case where the ordinary relief is employed. Also note all lands ground to same diameter.

or two, across the head, renders material assistance in keeping the piston head cool. The rib in the plane of the bosses may be dropped down to these, giving rigidity to the latter, as well as binding the ring-carrying portion of the piston securely to the lower half. The extension of this rib will permit a slight decrease in the thickness of metal back of the ring groove and it would seem that the pin boss might be of slightly less diameter when supported by a rib. In one or two cases, the objection has been raised that, due to the thermal property of the alloy, this rib carried heat to the one point it was not wanted. However, to my best knowledge, no trouble whatever has developed where this has been done. As an indication of the effect of ribbing, the case of a 5 in. piston is cited. The motor using this particular piston is a high compression one, developing in the vicinity of 175 hp. at about 1500 r.p.m. This piston is exceptionally well ribbed, the transverse rib extending down the side nearly to the bottom of the skirt, and but 0.008 in. clearance is allowed on the skirt. Before ribbing, the clearances necessary were some thousandths greater.

Piston Length

The calculation of the actual length of bearing a piston should have against the cylinder so that a safe working pressure should be exceeded at no time is too involved and would take too much time to warrant its determination here, other than to indicate the factors that enter into the problem. A mean pressure of from 25 to 30 lb. per square inch of projected bearing area is, I believe, not excessive for high speed motors.

Side-pressure is, of course, a tangential function and is expressed by an equation in the form

$$P_s = P \tan \alpha$$

P being the total force exerted by the piston and α the rod angle. The total force is not the gas pressure back of the piston but rather is the sum of such pressure and the inertia force. This latter opposes or is negative for approximately half of the stroke and is positive for the balance. Both, of course, vary with the piston position. It will be seen that the problem really depends upon the "cut and try" method for solution. The combined force must be determined for various crank positions, resolved into components perpendicular to the cylinder and the mean found. Investigation of several cases with the connecting-rod—stroke ratio two or higher has shown that if the actual bearing length is about the same as the piston diameter the mean side-pressure will not exceed the higher figure mentioned a moment since, that is, 30 lb. per square inch of projected area. However, the advantages of the long piston, especially in aluminum, are obvious and if it is possible to increase the bearing length, so much the better. If the length of the piston is always taken as one and three-tenths (1.3) to one and one-third (1.33) the diameter in the conventional three-ring one, the question of bearing length will almost certainly take care of itself.

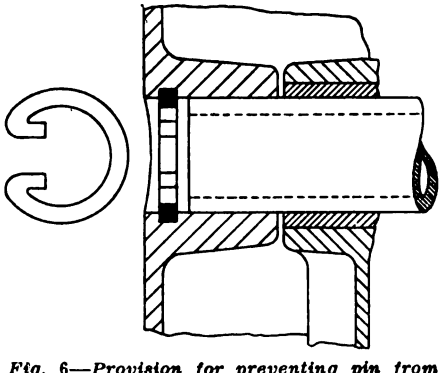

Fig. 6—Provision for preventing pin from scoring cylinder when free to rotate in either rod or piston

Wristpin Location

A detail of design meriting the fullest consideration is relative to the location of the wristpin. This point is approached with some little trepidation owing not to any great divergence of opinion as to its theoretically correct location, concerning which most engineers are, in the main, agreed, but rather because in advocating and urging that theory be put into practice, the question is going to be raised that motor cost will be increased. Undoubtedly, the conflict here between theory and practice is the chief stumbling block in the path leading toward standardized piston design.

In this connection the trend of design as shown by the prints in hand is worth a word of comment. If any conclusion is to be drawn from these prints, it is that many engineers in the last six months have approached this question from a new angle. Inspection of the drawings received prior to this time would seem to show that in the majority of cases the designer has had one or both of two things in mind. Possibly, in some cases an effort has been made to balance the piston about the wristpin. In other cases it would seem that the designer has endeavored to get the wristpin as near the head of the piston as possible, outside construction details apparently influencing him. The prints received showing that bearing considerations had had an influence on the wristpin location were exceedingly rare.

Recently, however, possibly as many as 25 per cent of the prints that have been submitted show that even distribution of side-pressure due to rod angularity has been the dominant consideration in the design of the piston.

Let us analyze the changes necessitated in a motor in changing the design of the piston in such way as to insure uniform distribution of side-pressure. As has just been stated the objection that is going to be raised to the conversion of theory into practice will be on the score of expense, due mainly to the fact that the over-all motor height must necessarily be increased to keep the operating conditions the same. This additional height represents a slight increase in weight, consequently, casting cost; also may increase very slightly the machining cost. There would seem to be no other reasonable objection except possibly in the eight in that it would increase the over-all width to an undesirable point. Especially might this be the case with eights with over-head valve construction. This objection I do not believe, can be raised in the case of the twelve nor in the case of the vertical motor.

As a matter of fact two manufacturers in this section have in their latest models increased the over-all height of their motors to permit the dropping of the wristpin which had formerly been nearer the head, to a point insuring this uniform distribution of side-pressure. The pistons (iron) in these motors were always a source of trouble in that they wore unequally and excessively and slapped badly until this change had been made.

In the consideration of the problem involving the determination of proper wristpin location the forces may be assumed to act in one plane. At first glance it might seem that if the wristpin axis were to lie in a transverse plane dividing the actual bearing portion of the piston cylinder into two equal parts the desired condition would be attained. However this is not quite correct since the friction between piston and cylinder introduces a turning moment about the

wristpin. Then if P represents the uniform mean pressure desired per inch of actual bearing length,

Total load $P = (L - l)\,p$

L being the total piston length and l the non-bearing length of piston. For reasons which are obvious, the rings do not enter into the problem at all. In taking turning moments about the wristpin, μ being the co-efficient of friction

$$p\,(x-l)\,\frac{(x-l)}{2} + \mu\,(L-l)\,p\,\frac{D}{2} = p\,(L-x)\,\frac{(L-x)}{2}$$

Simplifying

$$x = \frac{L+l}{2} - \frac{\mu D}{2}$$

D being the piston diameter.

The interpretation of this is that the proper location of the wristpin should be above the exact bearing center by a distance in inches equal to one-half the product of the coefficient of friction by the diameter. A similar method of reasoning may be used in the location of the wristpin in pistons utilizing a wiping ring. It will be seen the smaller the coefficient of friction, the nearer the center of actual bearing surface, the proper pin location.

Wristpin Bearing Length

Let us now briefly consider the relation of wristpin and piston. The method of locking the pin and rod together, rocking the pin in the piston seems to be gaining in favor and I should judge in approximately 50 per cent of the motors now being built this practice is being followed. It certainly has the advantage of being the cheaper construction and possibly a slightly longer bearing length may be had.

It may be assumed that the maximum load sustained by the wristpin is that caused by the explosion and which it really is when the motor is turning slowly. At high speeds on the power stroke it will not ordinarily be as great due to the inertia of the piston. In checking over a number of drawings this wristpin bearing pressure has been found to range between 2500 and 3000 lb. per square inch of projected area. In a few cases with the maximum explosion pressure figured as low as 400 lb. per square inch it has even been found that the wristpin bearing pressure will attain a pressure as high as 4500 lb. per square inch of projected area of the wristpin.

However, taking the low figure, assuming 2500 lb. per square inch of projected area to be the average figure, if l_w is the total length of bearing, d the pin diameter, D the piston diameter, and P the maximum explosion pressure per sq. in.

$$2500\,l_w\,d = \frac{\pi D^2 P}{4} \quad \text{or} \quad d = \frac{\pi D^2 P}{10{,}000 l_w}$$

l_w may be as high as seven-tenths with sand castings, but is usually limited to five-eighths (0.625) the piston diameter due to conditions surrounding the operation of the molds when the pistons are manufactured by the Cothias process. This has to do only with the case where the pin rocks in the piston.

Again assuming a maximum explosion pressure of 450 lb. per square inch,

$$\text{When } l_w = 0.6D,\ d = \frac{\pi D}{13.3} = \frac{D}{4.25}$$

An empirical formula of the form

$$d = \frac{D}{4} - \frac{1 \text{ in.}}{16}$$

for the diameter in which we are interested checks up very well with the previous one, and is easily solved by inspection.

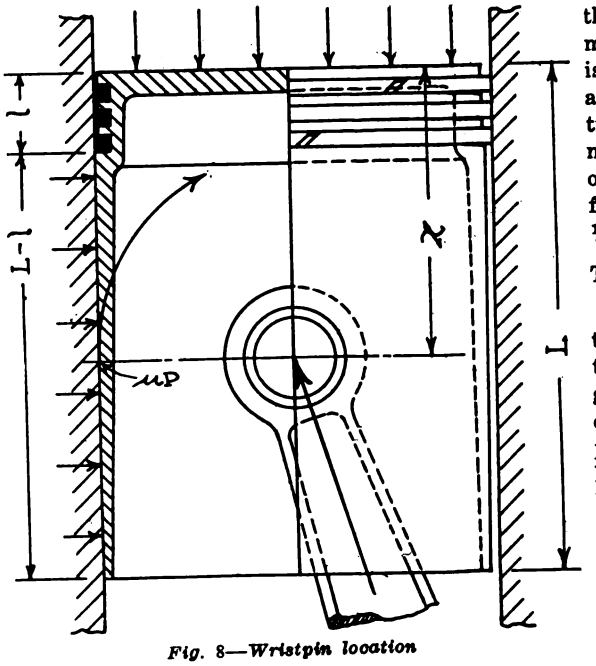

Fig. 8—Wristpin location

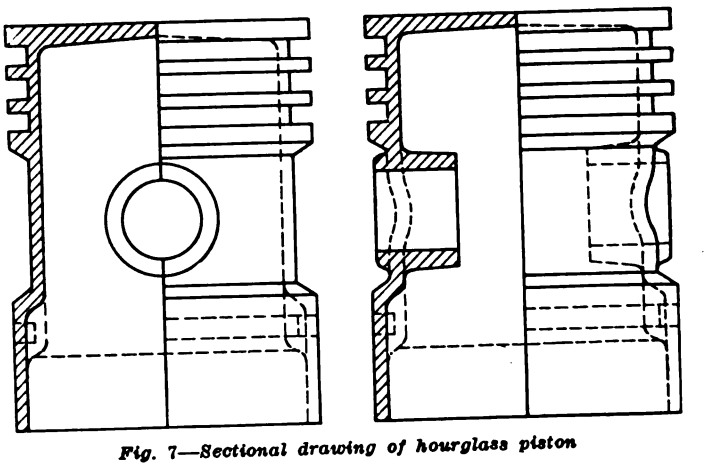

Fig. 7—Sectional drawing of hourglass piston

Occasionally it is possible to get a bearing length equal to sixty-five-hundredths (0.65) the diameter in this process when but one rib in the plane of the bosses is employed. On the other hand, if two ribs are desired a bearing length equal to six-tenths (0.6) the diameter is absolutely the maximum possible of attainment. More to the point, the distance between boss faces is represented by the complements of the percentages previously given; that is, the distance between faces will range from thirty-five-hundredths (0.35) to four-tenths (0.4) the diameter.

Wristpin May Have Wide Bearing

It may be said that up to this time we have experienced no difficulty whatever in retaining the specified width between bosses in the type of piston in which the pin is locked in the piston, in the manufacture of pistons by this process. In some cases connecting-rod bearing length as high as seven-tenths (0.7) the diameter has been secured.

Limitation of the Cothias Process

The wall of the Cothias process piston from the bosses down should be somewhat thicker than that of the iron piston since this process as presently developed does not permit the production commercially of pistons with the internal flange incorporated for stiffness at the bottom of the skirt. In explanation may be pointed out the fact that this process in the present art requires that the diameters of the piston increase progressively from the diameter at the head end, that is, the internal diameter of the ring carrying portion, to permit the withdrawal of the core. It is also necessary that slight allowance for taper be made. Examination of the various pistons we have made shows that the wall thickness of the finished piston will average from 3/32 in. for a 3 in. piston to ⅛ in. for a 4 in. one.

The Oil-Pumping Problem

Relative to some of the minor details of design a large number of the piston drawings show an oil groove back of the last ring with drain holes into the interior of the piston. I believe that experience has shown these drain holes should be at least 3/32 in. diameter to function properly, this regardless of the size of the piston. This provision for oil drainage is most important in the aluminum alloy piston where the clearances are neces-

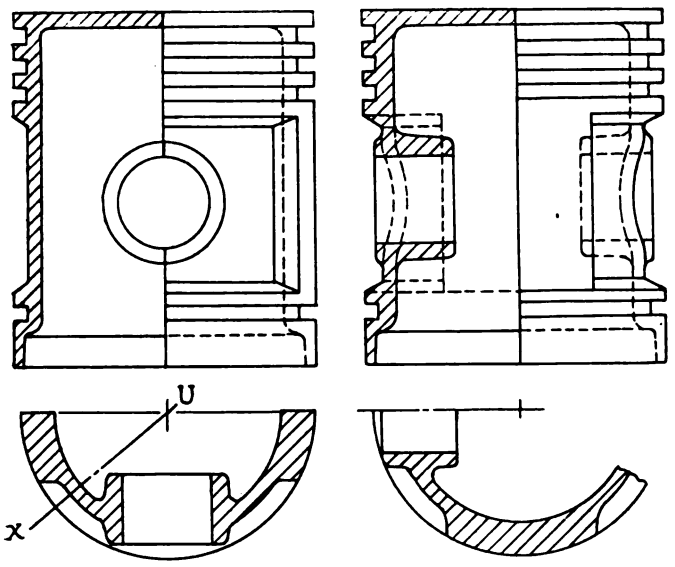

Fig. 9—Adaptation of hourglass type shown in section

sarily greater than with the iron one, the oil film being consequently heavier, since, this excess oil must either drain back into the crankcase or be pumped into the combustion chamber. Possibly the piston side-pressure causes a squirting action in addition.

In any event, as was mentioned some time back, in the case of several high speed motors where it has been found necessary to allow excessive clearance for the reasons given, it had been found most difficult to eliminate pumping of oil while running slowly, until this recess with drainage holes was incorporated in the piston.

Certain motors, however, due to the method of lubrication used, have required the employment of a wiping ring in the piston, to eliminate oil pumping. Incidentally, the use of a wiping ring, at least in all cases I have observed, has had a salutary effect on piston slap, even although in some cases the clearances have been unnecessarily great and slap should naturally have been expected. The "lag" of the piston due to friction in the ring groove, would seem to be the natural explanation for this agreeable condition.

The Hourglass Piston

In this connection since the results had with it have been quite remarkable insofar as the elimination of oil pumping is concerned, I would like to refer brefly to the hourglass type of piston. This type of piston was developed in Europe and its use has become more or less general on the Continent. At the present time pistons after this design are being employed on the Minerva, Clement and the Delage. As a matter of interest the pistons in the Mercedes 1914 Grand Prix winner were of this type. Two manufacturers in this country have recently completed a series of exhaustive tests with this type piston with such highly satisfactory results that it has been adopted as standard in their 1916 motors. In these two particular pistons, wiping rings are not employed, and the design has accommodated itself well to our process. This hourglass type of piston, in the main, is particularly well adapted to the Cothias process, and may very well include a wiping ring. It will be understood that for the same reasons that prevent the inclusion of an internal flange at the bottom of the piston, we are not able to include a flange to contain a wiping ring, at the same time maintaining an economic section. In other words, unless recourse is had to the hourglass type it is not possible for us to produce a piston with provision for wiping ring without sacrificing the fundamental advantage of the aluminum alloy piston, that is, lightness.

The general hourglass design may very easily include a wiping ring with a very slight, if any, increase in weight. The objection has been raised that bearing surface is being sacrificed. To provide additional bearing surface about the point where the side thrust is most direct, the Northway engineers have designed a piston in which the retraction is not carried the complete circumference, in effect bridging the gaps at the above locations. This Northway type has created much favorable criticism and several different pistons of this adaptation are now being produced.

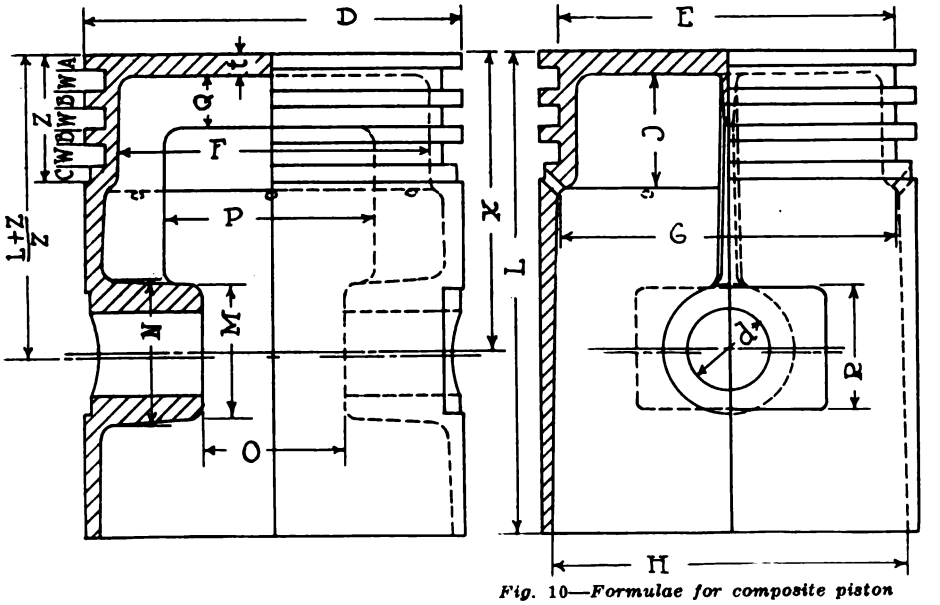

Fig. 10—Formulae for composite piston

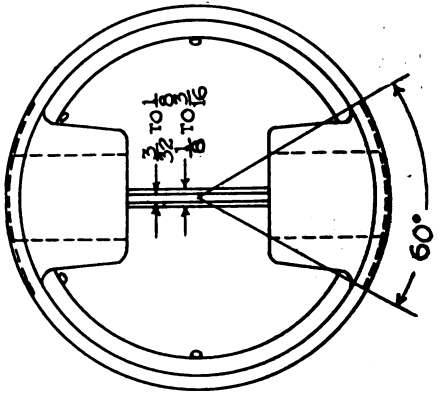
Ring Widths

Nominal Diameter		*Width*
2"	—2½" inclusive	1/8"
2⅝"	—4" inclusive	3/16"
4⅛"	—5" inclusive	¼"
5⅛"	—6" inclusive	5/16"

Proposed S. A. E. standard for piston rings and grooves



Key

A	*Width of first land* = *D*/16 — 1/16"	*L*	*Piston length* = 1.3 *D*
W	*Ring width* = *See table*	*J*	*Depth inside of head of ring carrier* = *D*/8 + 3*W* — 3/32"
B	*Width of second and succeeding lands* = *D*/16 — 5/64"	*X*	*Distance from head to wristpin center line* = $\frac{L+1}{2}$ — $\mu D/2$
C	*Oil groove* = ⅛" wide × 1/32" deep	*O*	*Distance between boss faces* = 0.375*D* to 0.35*D*
D	*Piston diameter* =	*M*	*Diameter small end of boss* = ⅜*D* — 1/16"
E	*Diameter bottom of ring grooves* = *D* — 1.7 *W*	*N*	*Diameter large end of boss* = ⅜*D*
F	*Diameter of ring backing* = 7 *D*/8 + ⅛" — 1.7 *W*	*d*	*Diameter of wristpin* = *D*/4 — 1/16"
t	*Thickness of head* = *D*/16	*P*	*Opening of rib* = *O* + ½"
G	*Internal diameter top of skirt* = 15/16*D* — 1/16"	*Q*	*Depth of rib* = *D*/8
H	*Internal diameter bottom of skirt* = 15/16*D*	*R*	*Width of relief* = *D*/3
l	*Non-bearing piston length* =		

If the width of the pad is made one-half the diameter, it follows that one-half the projected area is at least retained, while at the same time weight is being saved on two-thirds of the diameter. In laying out various sizes of pistons of this adapted design, I have found the sacrifice of bearing area to approximate 30 per cent. It must be borne in mind that even with this decrease in bearing surface, the friction load is still going to be less than for an iron piston with 100 per cent bearing on account of the difference in coefficients of friction. The sacrifice in thermal conductivity is even less in proportion to that of the iron piston.

Another matter is relative to wristpin hole relief. I believe it is now universal practice to relieve the piston at this point to provide for boss distortion. Ordinarily, this relief may be cast in the Cothias process piston, saving an expensive machining operation.

The Design of a Composite Piston

It occurred to me in the preparation of this paper that the prints in hand offered much interesting data. Therefore, I have gone over these, compiling data relative to the various details of design and in connection with the questions of design previously discussed, have worked out what might be termed a composite piston, at the same time bearing in mind when designing this, the limitations of the process. However, after all, this has not affected the design of this composite piston very much. Since nine out of every ten piston points received show pistons between 3 and 4 in. in diameter only those prints showing such pistons have been considered. The compiled data have been disregarded in no respect in laying out this piston. However, the length has been laid out on the basis of one and three-tenths (1.3) the diameter rather than one and one-fifth (1.2) as shown by the compilation. I felt warranted in making this change since a great many of the prints submitted were for iron pistons and as has been previously pointed out the greater the length the better it is for the alloy one.

The proposed standards for ring widths have been included. I procured the desired information from the Standards Committee but understand that no formal proposal has yet been made to the members of the Society.

Unfortunately, there does not seem to be any general agreement relative to ring thickness and I have therefore inspected these prints and have tabulated the data relative to the groove depths for rings of the widths on which it is proposed to standardize. This tabulation shows the groove depth to range between eight-tenths (0.8) ring width and eighty-five one hundredths (0.85) ring width. I have taken the higher figure, since I have had no means of knowing whether the rings were eccentric or concentric, and apparently, if the groove depth is the higher percentage, ample provision is made for the eccentric ring.

Further Discussion of C. S. Crawford's Paper on Eight

By Allen Loomis
Research Engineer, Packard Motor Car Co.

EDITOR THE AUTOMOBILE:—As C. S. Crawford's interesting and able paper on Characteristics of the Eight-Cylinder Engine was not given out until the meeting, when the reading was necessarily rapid and time for consideration limited, divers mathematical errors in it escaped attention and are printed in THE AUTOMOBILE for Nov. 4. The following corrections are submitted:

The figure of 70 lb., given near the middle of the first column of page 841, as representing the maximum unbalanced force at 1000 r.p.m., was, at the meeting, changed by Mr. Crawford to 140 lb. I remarked at the time that this implied a reciprocating weight in each cylinder equal to only 1 lb., 9 oz.; but not until after the meeting was my attention called to the figure of 2.375 lb., given in Table II. A proper calculation based upon this would correct the figure originally printed in the paper by substantially trebling it instead of merely doubling it, as admitted at the meeting. I hereby submit the calculation in abridged form.

The distance X through which the combined center of gravity of reciprocating weights in one side of the motor moves, as indicated in Fig. 6 of Mr. Crawford's paper, is found by computation to be 0.274 in.

As has been pointed out previously in the deliberations of this society, the combined center of gravity of all pistons in a 90-deg. V-type, eight-cylinder motor moves in a horizontal path through a distance equal to the distance X multiplied by 0.70711. This motion is harmonic and the complete double vibration occurs twice during each revolution of the crankshaft.

The maximum accelerating force in harmonic motion is equivalent to the centrifugal force of the same weight revolving uniformly in a circle whose diameter equals the length of the harmonic motion, in the same period of time required for the complete double vibration.

The radius, R, of this circle $= \frac{0.274 \times 0.70711}{2 \times 12} = 0.008073$ ft.

At 1000 r.p.m. of the crankshaft, or 2000 r.p.m. of the point under consideration, the linear velocity, V, of the point equals:

$$2 \times 0.008073 \times 2000 = 101.45 \text{ ft. per min.}$$

or

$$1.6908 \text{ ft. per sec.}$$

The vibrating weight, W, equals

$$8 \times 2.375 = 19 \text{ lb.}$$

Substituting these quantities in the ordinary formula for centrifugal force, $\frac{W V^2}{g R}$, in which g equals approximately 32.2, we find that the horizontal vibrating force in the Cole eight motor, at 1000 r.p.m. amounts to 209 lb. At 2000 r.p.m., this force equals 836 lb.

These figures greatly modify the resultant curves given in Figs. 4 and 5 published with the paper. The vibrating effect cannot be ignored either when one considers theoretically but properly that this force acts upon only one end of only the unsprung weight of the car, or when one actually compares the impressions obtained by riding in the tonneau of an eight-cylinder car and in the tonneau of a well-built twin six.

Even up to the present I have not had time to check all the computations in the paper, but wish to call attention to the obvious error in the computation of unit inertia pressure per square inch of projected area of crankpin given by the author in Table 7. The author has apparently taken into consideration the inertia effect of only the reciprocating parts of only one cylinder. It is obvious that the total inertia forces acting upon each crankpin of the Cole eight motor are actually due to the reciprocating parts in two cylinders plus the revolving weights of the connecting-rod big ends. The weight of the connecting-rod big ends is not now at hand, but it is probable that when the forces alluded to are properly combined, the unit inertia pressures for the motor will be found to be approximately treble those given in Table 7 of Mr. Crawford's paper.

The FORVM

SAND CASTING ARGUED FROM A FRESH VIEWPOINT—WHY PHOSPHORUS AND SULPHUR CONTENT S. A. E. STEELS IS NOT CHANGED—HOW SHOULD THE GNOME ENGINE BE CLASSIFIED?

Phosphorus Sulphur Content of S. A. E. Steels

EDITOR THE AUTOMOBILE:—On behalf of the Standards Committee of the Society of Automobile Engineers may I ask that you present a correction of one point in your very excellent report of the Chicago meeting in your issue of Oct. 21? On page 736 the statement was made that the suggestion will be given to the society next winter of raising the limits for phosphorus and sulphur in steel to 0.045 and 0.054 per cent respectively. As a matter of fact, the phosphorus and sulphur contents of the carbon steel grades up to those containing 0.45 per cent carbon were raised to 0.045 and 0.050 per cent respectively in January, 1914, and no change in these elements is proposed either for the carbon or alloy steels at this time.

In continuing the work of the iron and steel division, it has been the desire to take recognition in some way of the higher grades of steel which are demanded by some manufacturers for certain particular parts and the division has considered the listing of a separate schedule for this purpose. Since, however, the grades listed at this time are, in the opinion of the division, thoroughly adequate for the production of the great majority of structural parts and since the introduction of a separate list with no variant except in phosphorus and sulphur would probably have the effect of complicating our list, the action proposed at this time, to cover the situation, is to introduce in the text of our specifications a statement equivalent to the following:

"The compositions listed below include practically all the steel materials necessary for the great majority of automobile parts. In cases where very special duty or exceptional quality is demanded, grades containing less phosphorus and sulphur are available, but these should be made the subject of special agreement between buyer and seller. By such arrangement, manganese may also be limited within a variation of 0.20 per cent inside the limits given."—K. W. ZIMMERSCHIED, Chairman, Standards Committee, S. A. E.

Advantages of Sand-Cast Pistons

By W. M. Levett

President Walker M. Levett Co.

EDITOR THE AUTOMOBILE:—The fact that all of the American cars entered at the Astor Cup race were equipped with Magnalite sand-cast pistons, seems to have aroused much comment and it may be of interest at this time to give you some further facts relative to sand-castings for piston requirements.

As piston discussions have proved a rather important part in your Forum on the increased use of aluminum and aluminum alloys for automobile construction, the types and designs of alloy pistons which have met with the greatest success should prove of interest to your readers, especially in view of the agitation now on as to the comparative merits of sand and die castings.

We do not concede that a die-casting made under the conditions necessitated by the die-casting process will show as close a grain or as much strength as a sand-casting. The conditions of manufacture to which the aluminum alloy is subjected in the die-casting process result in impairing the vitality of the metal because of reasons readily understood by the foundryman.

Comparative examination will prove that our sand-cast Magnalite metal has more density and strength than that of the die-cast piston as commercially manufactured. As a matter of fact, our experimental department has made an examination of some die-cast piston samples by comparative tests and we have found the metal in these to show really not so great tensile strength as in our sand-cast pistons.

No Piston Trouble in Astor Cup Race

Of the eight cars to finish at Sheepshead Bay, only one—the sixth—was not equipped with sand-cast pistons of our metal and this car we understand was equipped with steel pistons. Among the foreign cars, many of which, we understand, used pistons machined from the solid steel billet, the principal trouble which eliminated them seems to have occurred in the form of broken connecting-rods or crankshafts, a condition which would indicate that the reciprocating parts of these motors were not of sufficiently light weight construction to stand the terrific strains of the 102-mile pace which was established.

Of the American cars eliminated—all of them, as stated, were equipped with Magnalite sand-cast pistons—we were unable to learn of a single one going out of the race because of engine trouble in this form. The results at the Astor Cup race, as far as sand-cast aluminum alloy pistons are concerned, is simply a repetition of the showing that has been made throughout the racing season. It might almost be said that this season's racing offered competitive contrast solely between our pistons and those in the foreign cars machined from solid steel billets, as with only rare exceptions, have other pistons been used in races of importance. Out of thirty-nine cars equipped with our pistons, which participated in twenty-five races during the season, seventeen have taken first place, seventeen second place and five third place—a condition which would certainly prove beyond any question, the toughness and durability of this metal for racing cars.

The writer examined a steel piston and connecting-rod from a Peugeot which came to grief in the Astor Cup races and found a condition in which the piston wristpin and connecting-rod were battered and bent to an amazing degree ascribed by the driver to excessive heat. Such a condition has not arisen and would not arise with the use of Magnalite parts, owing to the high thermal conductivity of Magnalite.

As for the castings themselves, there can be no question but that by means of a properly made sand core, a much

more substantial and practical system of ribbing is permitted than with the die-cast pistons. The special form of ribbing under the dome of the piston which we have worked out for racing cars, would be impracticable in any type of die-casting now used, and yet experience has shown this ribbing system to be an essential where extremely high speed of the engine and increased strength in the dome of the piston are absolute necessities.

The die-caster has endeavored to compensate for the lack of sufficient ribbing in die-cast pistons by increasing the section of the wall and head, but is he not by so doing throwing away a part of the very advantage sought by the use of aluminum alloy pistons, *i.e.*, a light weight piston?

To sum up—where tough, durable piston metal, where the use of the most advantageous ribbing, where the lightest possible piston is desired, sand-cast pistons must be used.

What Is a Rotary Motor?

By Edward V. Hartford

President Hartford Suspension Co.

EDITOR THE AUTOMOBILE:—Heterophemy, the using of one word when we mean another, is really one of the commonest mistakes in this world of error. I am led up to this remark by a curious example of heterophemy that occurs on page 706 of your issue for Oct. 14, where Charles Vivier, in a very able article on pistons and connecting-rods, calls the Gnome motor, a "rotary motor." Now, the Gnome engine is certainly not a rotary engine, in the same sense that a steam turbine is a rotary engine. A steam turbine usually consists of two parts, stator and rotor. The first is stationary, and the latter in rotary motion. The Gnome type has also a stator and rotor; the crankshaft is the stator and the remainder of the engine is the rotor.

The Gnome engine, however, is also a reciprocating engine, for notwithstanding the fact that they rotate, they have within themselves, pistons which reciprocate in the cylinders. Every mechanic will readily perceive that unless these pistons reciprocate, such a construction called a rotary engine, would, therefore, not be a prime mover; for they would be locked in such a situation—hence, it is obvious that no engine, with reciprocating parts may be called a rotary engine. The Gnome engine has reciprocating parts, and therefore, it is not a rotary engine. Nevertheless, it is hardly fair to call it a reciprocating engine, because that term has been so well standardized, and I believe that the best phrase to use, as indicated by the Editor of *Power* and the Editor of the *Scientific American*, would be to call them rotative engines, in which "the reciprocating motion of the piston is transformed into a continuous rotary motion."

In conclusion, I wish to state that I simply write, because a technical journal should be careful of how it picks its technical terms and expressions, and if this phrase "rotary engine" is once applied to the Gnome motor, it will stick very hard indeed and make it very difficult to eradicate this false impression from the minds of not only the trained engineer, but of the layman as well.

—The only truly descriptive term that has been suggested is "stationary crankshaft engine" but this is too cumbersome for general use. "Rotary cylinder engine" is another suggestion but this offers opportunity for confusion also. Perhaps "fixed crank" would be a possible solution of the difficulty, but any other suggestions would be interesting.—[ED.]

Rhode Island's Registration Analyzed

AN analysis of the registrations of automobiles and motor trucks in the State of Rhode Island up to Oct. 1 shows a total of 14,017 vehicles in use. These are the products of 243 manufacturers, a large number of whom, of course, are no longer active in the car and truck-building field.

Owing to the fact that a number of vehicles are registered under their trade name where the manufacturer makes both passenger cars and trucks it is impossible to tell exactly the number of each. However, counting each of these manufacturers as passenger car producers only, there are 215 of these represented as compared with twenty-two truck builders and six makers of electric cars. On the same basis there are 13,888 passenger cars, seventy-one motor trucks and fifty-eight electric machines.

Going by the number of cars of each make registered Ford leads with 4413, Cadillac being second with 1070, Overland third with 817 and Buick fourth with 719. Then come Packard with 394, Studebaker 388, Maxwell 365, Reo 319, Chalmers 307, Hupmobile 303, Hudson 254 and Pierce-Arrow 249. There are twelve other manufacturers who have over 100 cars each registered, the other 219 varying from Peerless, with 99, down to a large array with but one vehicle.

The History of the American Automobile Industry

Third Installment of the Complete History of the Industry in America, Taking Into Account Its Antecedents in Europe —Complete History To Be Published Later in Book Form

This Week the Development of the Steam and Electric Vehicle and the Good Roads Movement

By David Beecroft

ANOTHER brilliant American inventor, John Fitch (1743-98), originally a prosperous jeweler and watchmaker at Camden, N. J., took up the manufacture of arms during the Revolutionary War at Bethlehem, Pa., and designed a steamboat in 1775-6. He built a model in 1785 and a full-sized boat in 1788, which was tested on the Delaware from Trenton to Burlington, making a speed of about 8 m.p.h. and doing as much as 80 miles in a single day. This boat was propelled by vertical paddles operated by a crankshaft, the upper end of the paddle being in a guide and the blade traveling an elongated elliptical path as it moved backward in the water and forward over it. That it was not continued in use and others made was no fault of the mechanism or of the maker, but solely because conditions were not satisfactory at that time.

Early Steamboat Construction

In 1804 William Stevens, of Hoboken, built a boat which was capable of traveling 8 m.p.h. and which was operated for a few weeks. This boat employed a boiler having copper tubes, although we do not know whether this was a distinct invention or whether he knew of the tubular boiler invented by Read a dozen years before. Many people believe that Fulton took advantage of Stevens' work and embodied it in his successful device of 1806, but although it is quite certain that Fulton knew of Stevens' efforts, it is also certain that Fulton was abroad while Stevens was doing his work and that Fulton had plans for a submarine in 1793 and that he tried to interest foreign nations then at war in them, that he published books or pamphlets describing them about 1796 and as late as 1801, and made experiments at Havre and Brest in 1803. Fulton's success must, therefore, be considered as due to finding the right condition rather than to any superior mechanical ability or to his making use of any rights belonging to others. Too often this has been the history of pioneers, and it is a disgrace to modern methods that even now we allow much talent to go unrecognized, seeking helplessly for the assistance and opportunity, that, properly aided and directed, could do much toward making the world better and richer.

With the passing of the year 1800 in America the seeds of motor transportation had been scattered and if the progress was slow from that date up to 1880, when the period of steam automobiles with which we are all familiar began, it was due to a variety of conditions. Population was sparse, roads did not exist in many places, and there were diversions of interest. The practical steamboat was demonstrated in 1804; railroads were started in America in 1809; the hot-air engine was receiving attention; in 1832 the first street car was operated in New York City by horses; in 1837 the electric boat was demonstrated, and in 1842 the first electric locomotive demonstrated what it could do.

Thus, beginning with 1800 began a period of diversity of energy in solving mechanical transportation. The field was not left open to steam, and what steam possessed was divided among the steamboat, railroad and the steam road vehicle.

From 1800 to 1880 the thread of steam development in America is a difficult one to follow, lapses of years passing without any definite record of progress. It will be necessary to introduce both boat and railroad progress in steam at times in order to get the proper perspective of the steam road vehicle through these years of evolution—years in which progress was materially retarded by the absence of roads and years in which the road vehicle was lost sight of by many, due to the faster development of steamboats and railroads.

The Use of Rails

The use of rails in lieu of good roads is much older than the locomotive on rails for it must have been very early apparent that wheels could be assisted over bad roads by laying down rails of some sort. On the other hand, this use could not have been very common because of the lack of suitable rail material. The first record of railways in America indicates that Thomas Leiper, near Ridley, Delaware County, Pa., laid about a mile of track in 1809 to move stone from a quarry. Part of this track was exhibited at some sort of gathering July 31 of that year.

Some claims were made that Silas Whitney had a similar short stretch of railway at Beacon Hill, near Boston, 2 years earlier. It must not be sup-

posed that these rails resembled present railway rails; they were most likely wooden logs hewed to furnish a flat surface, and mortised together at their ends. Because these wooden logs wore out unevenly and were short-lived at best, they were at a later date commonly covered with iron strips on which the wheels ran. These iron strips, at first cast but later of rolled material, resting on the soft wood, would bend more or less as the wheels rolled over them, and eventually break. Frequently their retaining spikes became loose and permitted the ends to rise and become entangled with the vehicle overhead. We therefore see in these inferior constructions another reason why conditions were so difficult for the inventor and progress so slow.

To establish a chronological comparison with railroading in England, the first locomotive was tried on rails in England in 1784 while in 1788 Symington, having abandoned his road carriage model, made a small model steamboat which he tested on a small English lake. In this same year Robert Fourness and James Ashworth obtained a patent on a traction engine for drawing other vehicles. It is not known whether this device was actually built or not, but it is interesting as showing a three-cylinder, vertical, non-condensing engine. Many others were undoubtedly working on the problem at this time and each contributing their small part toward the final success.

Development of American Roads

The reason for road locomotion in America dropping far behind that of Europe, particularly in England and Scotland, was because of the road movement being far behind in America. A brief comparison of road activities is necessary here.

The rapid development in European roads started a movement in America. Congress in March, 1806, appropriated $30,000 toward the surveying and construction of a road from the Potomac, near Cumberland, Md., to the Ohio at Steubenville, Ohio. The length first opened was 130 miles and cost $1,700,000. The first horse stage coach carrying United States mail from Cumberland to Wheeling passed over this road in August, 1818.

How to raise money for these expensive roads was a considerable problem not only in the United States, a country of large distances and little wealth, but even in England, and one of the solutions of this financial problem was the giving of franchises to private corporations which were permitted to construct roads and charge toll for their use. The toll system was probably at first a form of brigandage and is mentioned by the Historian Strabo as existing on roads leading from Babylon to Syria. Many present-day road users can testify that it has not lost its ancient character. In 1346 the toll system was adopted definitely as a means of raising revenue for road maintenance and repair in England, but not until the latter eighteenth and early nineteenth century period did the toll system for raising road revenue become really popular. It rapidly grew, until 1838 showed fully 1100 turnpike trusts existing in the Kingdom. The cost of collecting tolls, however, often nearly equalled the income, and the census of 1871 showed 5000 collectors in England and Scotland. In 1857 Ireland freed herself from toll gates and in 1878 Parliament abolished tolls in England, but this archaic system still exists in some of the older and less progressive parts of the United States.

Lancaster Pike First Toll Road

The first toll road in the United States was the Lancaster pike, 62 miles long, authorized in 1792, and still collecting tolls; a monument to permanent private franchise. By 1811 more than 300 turnpikes had been chartered in New York and New England with a combined length of 4500 miles. In 1828 over 3100 miles of chartered turnpikes existed, of which over 2380 miles had been completed at a cost of nearly $8,500,000. The advent of the locomotive and transportation on rails soon after attracted the attention of the American public and the American road was left to itself. Even the great national highway, originally planned to reach St. Louis, vanished in a more or less incomplete end on the prairies of Illinois. This short account of the early roads accentuates the interdependence of the good road and the motor vehicle and partly explains why the second decade of the last century showed so little activity in the motor vehicle field.

Compared with America the road movement in Europe was immeasurably stronger. In fact, roads were the most potent influence in stimulating the development of the motor vehicle.

France was really the leader of the modern road movement, some 15,000 miles of hard road being built by enforced peasant labor under Colbert, who was appointed comptroller of finance in 1661. The present French system was really founded by Napoleon, who adopted very largely the innovations instituted by Tresaguet and perfected a splendid administrative system. P. M. Tresaguet, 1716-1796, was a great engineer and made many improvements for river navigation, but we know him only as a great road builder, and practically the father of modern road work. He recognized the need of constant maintenance and devised means for securing this. He improved the construction, reduced the cost, crowned the foundation so as to secure drainage, reduced the depth of broken stone used and, particularly, organized the caretakers who are the very backbone of the present French road system.

John L. MacAdam, England, 1756-1836, was not the inventor of the macadam road, for it was then used in several parts of Europe, but he seems to have been the first to fully grasp and explain the theory of the broken stone road without a paved foundation. As a youth he resided in this country, but returned to Scotland in 1783 and was soon appointed magistrate and trustee of roads. In 1816 as inspector for the Bristol turnpike trust, he supervised the reconstruction and repair of 178 miles of roads. In 1817 he built the first macadam roads in London, and the system which he advocated slowly spread throughout the Empire.

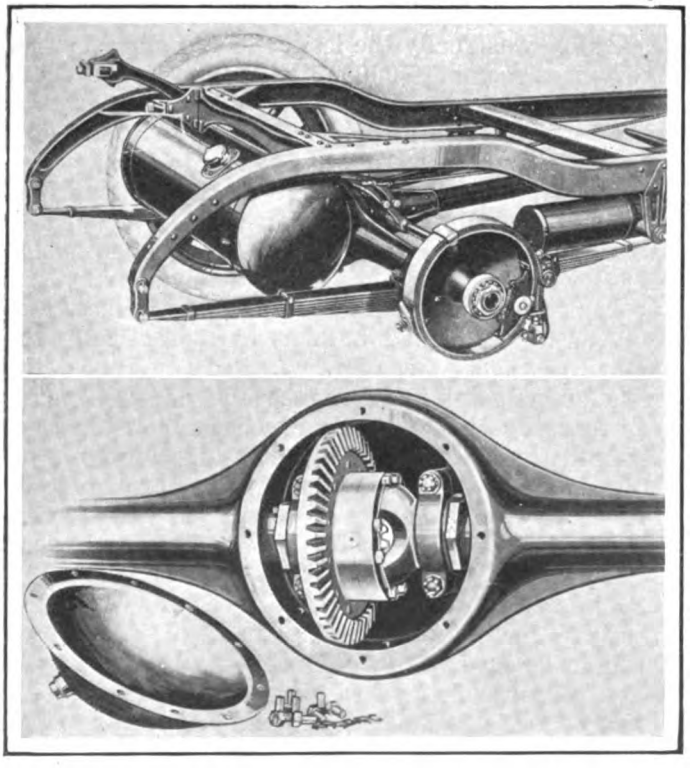
Allen Line Two Models on One Chassis

Bore ⅛ in. Larger—Wheelbase 2 in. Longer—Floating Rear Axle—Rounded Radiator, Built-in Windshield and Molded Line Bodies Improve Appearance—Other Refinements.



Upper—Rear construction of the Allen chassis for 1916, showing how the frame sweeps up and over the axle and joins to the underslung springs with a shackle at the end. Note also brake construction and fuel tank mounting. The floating rear axle is carried on Gurney bearings, the weight of the car resting on the pressed steel housing. Note cross rod equalizers for the brakes directly in front of the axle shaft

Lower—Allen floating rear axle with cover plate removed, showing mounting of bevel gear. This illustration gives an excellent idea of the accessibility of the assembly

TWO models on a single chassis will make up the line of the Allen Motor Co., Fostoria, Ohio, for the 1916 season. These are known as models 32 and 37 and are a roadster and a touring car, both selling for $795. Before this season the Allen company has been manufacturing five models and the decision to change to two models on one chassis is in line with the policy of concentration which is the tendency during the past few seasons.

Motor and Car Larger

This season the car is larger in practically every respect than it was a year ago. The motor has ⅛ in. more bore, the dimensions now being 3¾ by 5 and the wheelbase is longer by 2 in. than in last year's model, the length now being 112 in. This season the rear axle is a floating design and in exterior appearance there has been considerable alteration, due to the addition of a rounded radiator, a built-in windshield and a molded line body.

Doors 2 In. Wider

The doors are 2 in. wider with concealed hinges and the tonneau is roomier due to the increased wheelbase which has been entirely utilized in giving room to the passengers. The upholstery is easier sprung than last year, having better padding and higher grade material. A one-man top is now used, and on the instrument board has been added an electric light. Another improvement is the placing of the electric signal button at the top of the steering column. The front compartment is also roomier, providing leg room for the driver.

Block L-Head Motor

The motor is made in the plant of the Allen company and has its four cylinders cast in a single block. It is of conventional L-head design with the valves inclosed. It is cooled by the thermo-syphon system which operates in conjunction with a tubular radiator having a rounded shell. Lubrication is by a combination pressure and splash system and starting, light-

ing and ignition is supplied by a Westinghouse two-unit outfit. One of the innovations for this season is the introduction of Stewart vacuum feed.

Floating Rear Axle

A cone clutch faced with leather having a diameter of 13¾ in. and a face width of 2⅜ in. takes the drive from the motor and delivers through a three-speed selective gear to a floating rear axle of bevel type having a 4 to 1 ratio. The drive is through a single universal joint and the rear axle is carried on Gurney bearings, the weight of the car being taken on the pressed steel rear axle housing. The brakes are 12¼ by 1¾ in. service and 12 by 1¾ for the emergency, the service brake being contracting and the emergency expanding. The brake connections are fitted with equalizers.

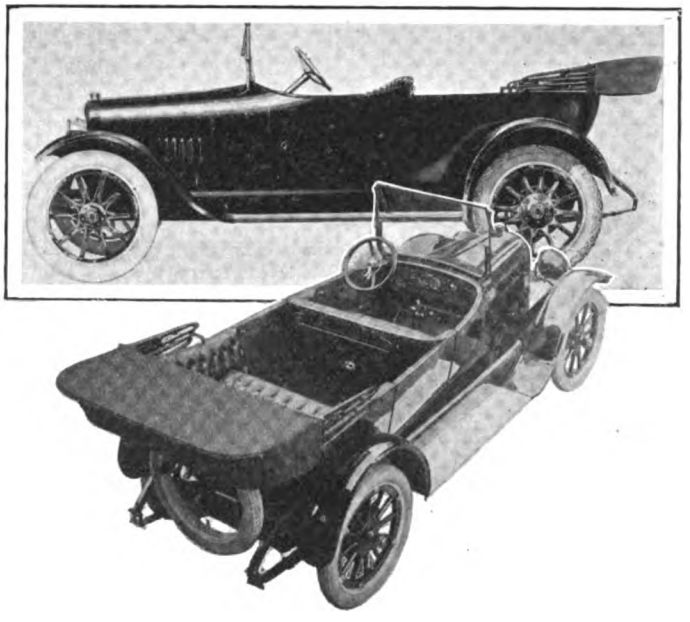
The front axle is a one-piece drop forging of carbon steel. It has an I-section. The frame is of channel section pressed steel and is braced by four cross members. High carbon steel springs are used, both front and rear being semi-elliptic, the length of the rear being 55 in. long and 2 in. wide. The wheels are 3 in. artillery type and carry Firestone demountable rims with 32 by 3½ straight side tires. The tread is standard 56 in., the road clearance 10½.

Body Features

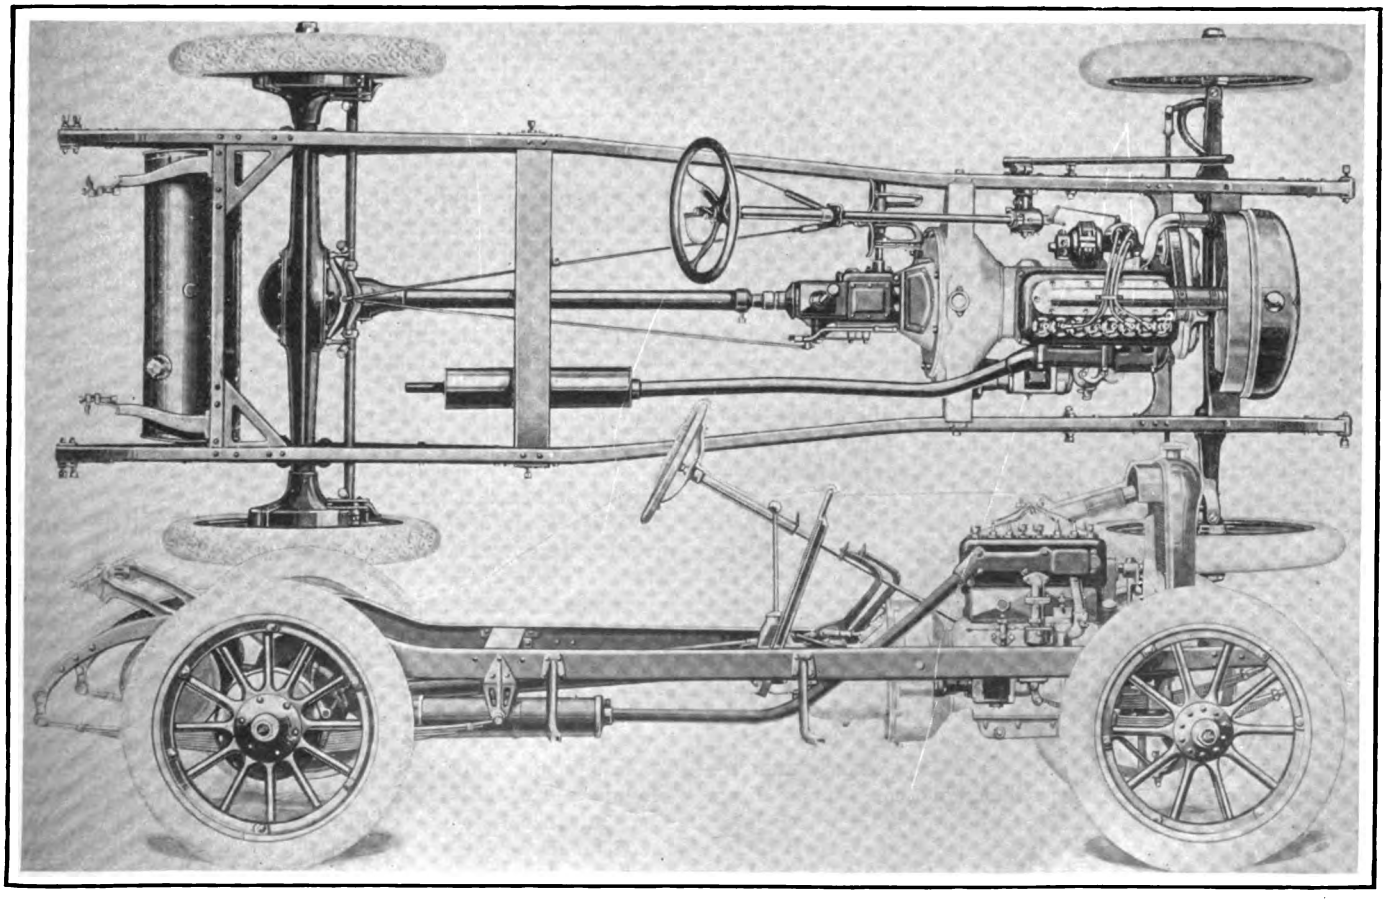
Features of the body, which is of five-passenger capacity, are the boat-like exterior and the wide doors with concealed hinges. Flush type upholstery is used and the floorboards are covered with linoleum with aluminum bindings. The instrument board contains a speedometer, lighting, starting and ignition switches, air control lever and an instrument board light. These are all flush mounted except the instrument light.

Equipment Is Complete

Black japanning is used on the fenders and radiators with the body, hood and wheels olive green. The trimmings are nickel and aluminum, and the equipment includes starting, lighting, combination tail light and license bracket, horns, speedometer, rear tire irons, extra demountable rims, rain vision windshield, one-man top with side curtains and slip cover, compound pump, tire repair kit and a complete tool kit and jack. The specifications of the roadster are the same as for the touring car except for the body, which is provided with a rear compartment accessible from either side and from the rear.



Two views of the 1916 Allen five-passenger touring car for 1916, the lower giving a good idea of the new body lines and the high narrow radiator



Plan and elevation of the four-cylinder chassis which constitutes the Allen line for 1916, showing mounting of power plant and fuel tank. Note strong cross members and also brake equalizer connections and rear tire carrier

Mobile Repair Shops Give War Service

With Tools and Equipment Mounted on Trailers These Shops Can Keep in Touch with Army Cars and Trucks for First Aid Work—Generally 25 Miles From the Front

By W. F. Bradley
Special Representative of THE AUTOMOBILE *with the Allied Armies in France*

PARIS, Oct. 23—The popular impression that automobiles are short-lived in war service is not borne out by facts. One of the French armies, located at a very active point of the battle front, has roughly 2000 trucks, touring cars and special automobiles in service. The three repair shops attached to this army, and established a short distance to the rear of the lines, handle on an average 300 cars per month. Obviously the number of cars going through the repair shops is a very variable quantity, running high when there are attacks and falling very low when the opposing armies are inactive. The average of 300 repair jobs per month for a fleet of 2000 cars is based on one year's operations and includes stationary trench warfare and a period of very fierce attacks. The automobiles comprise all French makes and five makes of American trucks, as follows: Packard, Pierce, Kelly, White and Jeffery.

Engineers Broaden Their Experience

According to one of the officers in charge of one of the three repair shops, the American trucks give just as good service, on an average, as those produced by French firms. This officer, it may be mentioned, is in civil life the chief engineer of a French automobile firm producing a high-grade car. This officer, together with others engaged on repair work at the front, is of the opinion that he is attending the finest school of experience in the world. He states that in twelve months' repair work at the front a practical engineer can acquire more data and more practical experience than in twelve years of peace conditions. It is thus a mistake to suppose that the engineers of warring nations are standing still while the war is in progress. They are able to examine and compare the working of all classes of automobiles—French, English, American, Belgian, Italian and German—under arduous conditions and in the hands of poor drivers. The reports which an observant engineer is able to send home to his factory are of an unusually valuable nature.

In this particular army, located in the Champagne district, with its repair shops only 25 miles to the rear of the front line trenches, it is found that the percentage of scrapped automobiles is very little higher than under peace conditions. There is more repair work to handle than in civil service, for conditions are more hazardous and drivers cannot be selected with the same care, but this does not imply a greater percentage of scrapped vehicles. It is surprising how difficult it is to put an automobile entirely out of business by shell fire. Bodies are very frequently destroyed by fire or by shells, but they are very readily replaced, and it requires a direct hit or very heavy shell fire to make a chassis unfit for further service. Even trucks which have come under direct fire and have had to be abandoned have been captured later, towed home and put into service again.

The diversity of the work undertaken by automobile trucks is not realized by the manufacturer abroad. In addition to carrying ammunition and food to the troops in the trenches, every truck is equipped for carrying men and also for hauling guns. An immense amount of trench-making material has to be hauled by automobiles, as well as men and material for making special roads. Under present conditions the big guns rarely remain in one position more than 24 hr., and when it is required to remove them the automobile trucks are called upon in preference to horses. This of course applies to the big guns, and not to the 75 mm. field pieces, which are light and quickly removable by means of horse teams.

Moving the Big Guns

The necessity for frequent and rapid removals of big guns had been foreseen prior to the war, with the result that four-wheel drive tractors had been put into service in fairly large numbers. These, however, are not sufficient for all needs and ordinary 3-ton trucks are called upon to tow heavy guns. After being in operation for a day the guns change position at night, with the object of keeping the enemy constantly guessing as to their exact position. As far as possible, gun positions are selected near roads. Where roads do not exist, they are made specially by the use of logs placed transversely on the track. Automobiles are invaluable for such work, for by their aid it is possible to build special tracks to gun positions in a night.

Mobile Repair Shops

The automobile repair shops at the rear of the lines are capable of undertaking any kind of work, and yet can be moved to any new position within an hour of the order being received. This method of working is not common to the whole of the forces in the field. Some branches of the army, and particularly the British army, have permanent repair shops from 50 to 150 miles to the rear of the battle line, the damaged vehicles being sent to these shops by train, and returning usually under their own power. In these cases ordinary factory conditions pertain, and most of the men working in these permanent repair shops have never seen any fighting or heard a gun fired.

In the repair departments immediately behind the armies mobility is secured by mounting each tool on a special trailer truck. Two or three of these trucks are fastened up behind an automobile and hauled away to whatever new position may have been selected. The equipment comprises lathes, drilling machines, grinding machines, a case-hardening plant, and all the smaller tools required for general repair work. Electricity is used for driving the machinery, a gasoline engine and dynamo carried on a trailer being provided for this purpose. While it is essential that these repair shops should be self-moving, and capable of keeping pace with every advance or retreat of the main army, it is not necessary for them to work absolutely in the open. They can operate most effectively at an average distance of 25 miles from the front, and at this range it is generally possible to find buildings which can be readily converted to repair shop work. An

abandoned factory, a street car depot, stables or a farm with a big courtyard all form convenient centers in which to establish the repair depots. Such widely different localities as a village school and an abattoir are selected as places suitable for working in, while a factory with electric power is looked upon as ideal.

Shackle Bolts Inadequate

The units which are picked out as giving most work to the repairman are shackles and shackle bolts and springs. According to one engineer-officer, there is not an automobile truck of any make or any nationality with really adequate shackle bolts. On war service these bolts are never lubricated by the driver; indeed they are generally in such a condition that it is impossible to lubricate them, and no provision is made for an automatic supply of oil or grease. The shackle bolts of a truck working over rough roads are subject to as much stress as the wristpins within the motor; yet these latter are absolutely protected from dirt and are perfectly lubricated, while the former have no protection and no lubrication. In a rather less degree than the bolts, springs also suffer from the lack of lubrication and attention, although the breakage of springs is not as frequent as the breakage of bolts.

War Conditions Affect Lubrication

War service has shown that mechanically operated forced feed lubrication to all motor parts is not as perfect as was generally supposed. One engineer-officer, who makes use of forced feed lubrication in his own motors, has taken careful records of all lubrication troubles on trucks and touring cars with the conclusion that circulating splash gives the least amount of trouble. It is found that on war service care is not taken to change oil at sufficiently frequent intervals, poor oil is sometimes used, dirt is often poured into the motor with the oil, and by reason of the high pressure maintained these impurities are forced into the bearings.

This objection cannot be brought against forced feed lubrication in civil life, for the driver or owner can be relied upon to exercise sufficient care to keep dirt out and change impure oil at sufficient intervals.

With the ordinary circulating system to the important bearings and constant level troughs for the connecting-rod ends, there is not sufficient pressure for dirt and particles of metal to be carried along and forced into the bearings. Under the rough conditions at the war the methods of oil filtering with forced feed lubrication systems are altogether inadequate. It would appear advisable to have an oil reservoir entirely independent of the base chamber with some method of filtering equivalent to the oil filters and economizers used in factories. The oil tank independent of the motor has already been adopted on some European racing cars, and also on the latest French aviation motors, but this has been done more with a view to keeping the temperature low than to freeing the oil of impurities. The war figures show that there are 20 per cent more bearing troubles where the forced feed system is employed than with the circulating systems. This conclusion is significant in view of the fact that it has been arrived at by an engineer who was the first in France to develop the long-stroke, high-speed motor and the first to lubricate with pure castor oil delivered to the bearings at high pressure.

Clutches and Poor Drivers

Although clutches do not come into the repair shops for a great amount of direct treatment, yet war has shown them up as somewhat unsatisfactory and responsible for a good deal of damage to various parts of the transmission. In the hands of a skilled driver, or even with a man who takes an interest in his car, almost any kind of clutch will appear satisfactory. But unskilled army drivers, operating pedals through thick soled boots or wood clogs stuffed with hay, very quickly find out the weak points of a clutch. Even the best leather faced cone clutches can only be described as moderately good under war conditions. Multiple-disk clutches running in oil are rather better, but require attention to keep them in first-class condition. The only type of clutch which is absolutely foolproof and with which an unskilled driver can be relied on to change gears in a satisfactory manner is the single plate dry clutch. The war has shown the necessity for making clutches absolutely foolproof.

Simplification to Result from War

There is nothing to indicate that the war will bring about radical changes in truck design, but it certainly will be responsible for numerous detail improvements and a large amount of simplification which will tend to the general betterment of commercial vehicles. There is not a single make but is open to improvement in some respect, and the war offers an excellent opportunity to wide-awake manufacturers to improve their product. French firms have better opportunities of profiting by the war than any others, for they all have some members of their engineering staffs with the convoys or in the repair shops at the front, and these men are sending back detailed technical reports on their own and every other make of automobile. It is obvious that these reports must be more valuable than those obtained by foreign firms which only send an occasional representative or inspector to the scene of operations.

Three-Tonner the Favorite

The type of truck which the war has shown to be most suitable is the 3-tonner. Above this weight trucks are too heavy and too big for general conditions; below that weight they are too small and are liable to be overloaded. The war has shown the necessity for uniform platform heights, so as to facilitate loading and unloading. It is quite likely that a standard height will be agreed upon in each country, so as to accord with the height of railroad trucks and loading platforms. Even now radiators are not given sufficient protection for war service. The substantial buffer uniting the ends of the frame members, as on the Packard truck, is considered insufficient by the French, and is supplemented by bars to the full height of the radiator. Bars attached to the radiator, as on some of the London buses, are also inadequate. It should be remembered that trucks are liable to collide with overhanging bodies, and that in such cases a protecting bar on the level of the frame members is of no use whatever.

—

Amalgamite Self-Lubricating Bearing

CHICAGO, ILL., Nov. 6—A new self-lubricating bearing, in which graphite is intimately mixed with the metal forming the bearing and in which bearing no other lubrication other than that afforded by the graphite is needed, has been brought out by the Dann Spring Insert Co., this city, which is furnishing the bearing for small bushing work such as spring eyes, universal joints, steering gear, and similar parts. This new self-lubricating metal, known as Amalgamite, is a compound in which the bearing metals are pulverized physically rather than melted by heat. In this pulverized condition the metal is mixed with air-floated flake graphite, the metal and the graphite being pressed into a steel shell which serves as a container for the bearing compound, many tons pressure being used in the work. Thus, instead of pouring the bushing it is pressed into formation. The graphite is not in layers, spotted, put in depressions in the metal or held in the metal by any adhesive but is mixed physically so that the cellular structure of the metals is intimately combined with the graphite, the theory being that it is a molecular mixture of the metal and graphite, so that graphite is a part of the warp and woof of the bearing.

The Rostrum

Water May Help Carbon Troubles

EDITOR THE AUTOMOBILE:—A copper tank, adjusted to the exhaust pipe, containing 2 qt. of water is connected by copper tube to intake manifold. The suction of the intake stroke takes the vapor with mixture to explosion chamber. Provided the small amount of water in the vapor gets to the chamber, will it cause more power, less carbon and tend toward economy?

Needham, Mass. F. T. R.

—There are many theories advanced for the action of water in the intake manifold and all of them are combated just as strongly as they are advanced. One of the theories held quite widely is that the water if entering in very minute quantities will be transformed into steam which on coming in contact with the blowing carbon will form carbon dioxide, thus cleaning the cylinders of carbon. It is generally accepted that no increase in power is given by the admission of water. There does not seem to be any reason why the economy should be better.

Hupmobile Oiling System Satisfactory

Editor THE AUTOMOBILE:—Can you tell me what lubricating system I could put on a Hupmobile model 20 other than the one which is now used by the Hupmobile company on this particular model?

Evansville, Ind. P. C. F.

—If desired a pressure feed could be put on the Hupmobile 20 but this would be altogether unnecessary as the gravity system now in place is an excellent one and works out well for any speeds of the car. The cam adjustment on the top of the oil box on the side of the motor provides a faster or slower proportional flow in coincidence with the throttle opening and gives all the oil necessary. To install the pressure feed it would mean an externally driven pump that could be taken by friction from the flywheel, which is at the front end of this motor. The oil leads will then have to be run into position and altogether it would make a job which would be more complicated than necessary.

Ammeter for Delco on 1914 Cole

Editor THE AUTOMOBILE:—Please advise how to connect up an ammeter to the electrical system, Delco, of a 1914 Cole 4-40.

Newark, N. J. E. C. McC.

—In installing the ammeter in the generator circuit of the 1914 Cole-Delco system, follow these directions:

On the top cover of the Delco motor-generator, rear end, are two terminal posts. The smallest one is the generator shunt field post and is connected to the bottom terminal of the voltage regulator tube. This generator post is not to be disturbed.

Remove the cable from the largest generator terminal post (which is the main generator positive post), cut off the brass terminal clip and pull this wire out of the metal conduit. Mount the meter at the desired location, and this loose, free wire, that has been removed from the metal conduit, connect to the negative post of the ammeter. Pull a new cable into the metal conduit, and connect one end to the positive post of the ammeter, the other end being connected to the main generator positive post, replacing the cable that is connected to the negative post of the ammeter. The brass terminal clip should be resoldered on the generator end of the cable that is newly installed. This arrangement places the ammeter in series in the main generating circuit.

An ammeter should be used that has its zero near the center of the scale, an 10-0-30 instrument being the type most commonly used for this work. When thus connected, the ammeter will indicate a discharge when operating as a shunt motor, as in starting, just prior to cranking the engine; indicating the charge rate, when the engine is running, and no ammeter reading will indicate trouble in the generating apparatus.

Possibly Oil in Commutator

Editor THE AUTOMOBILE:—I have a 1916 Maxwell car, and would kindly ask you to inform me just what may be wrong with the electric lighting and starting system on this car. The ammeter charges as long as I keep the car running above 10 or 12 m.p.h., but when I slow down to less than this number of miles for a little while and then speed up to even 25 m.p.h., the ammeter does not indicate charging, but remains at 0. Then, if I stop the engine, and start again, the ammeter continues to charge as before. I have used the car about six weeks, have run it 650 miles and the test of the specific gravity of the storage battery is 1250 or a little more. The mechanic at the service station in our city has not been able to locate the trouble, and does not think there is anything wrong. What do you say?

Hagerstown, Md. E. C. B.

—It is possible that all the connections are not tight and that they occasionally make poor contacts, decreasing the output due to the additional resistance. It is also found that oil in the commutator or brushes will cause trouble similar to that you describe. This is due to the fact that at low speeds the oil will sufficiently insulate the brushes from the commutator so that when the generator just commences to turn over and is producing only about 1 volt, the oil will prevent a circuit so that the output is zero. Of course, at times when running at high speed, the brushes may be able to touch the commutator, allowing the fields to become saturated and the output normal. It is also possible that the ammeter needle may be sticking and the vibration of the car at high speeds is sufficient to loosen it.

Compression Space for 85 Lb. Per Sq. In.

Editor THE AUTOMOBILE:—What are the cubical contents of the compression chamber for a 5-in. bore by 7-in. stroke motor above the piston when it is on top dead center, to get 85 lb. compression cold, assuming that the inlet closes 30 deg. past bottom dead center?

New York City. J. H.

—The displacement of one cylinder of a 5 by 7 motor is 137.5 cu. in. According to accepted tabulations in order to obtain 85 lb. compression the cylinder clearance should be about 23 per cent of the piston displacement figuring low.

With this percentage the volume of the compression space would be 31.625 cu. in.

The above clearance is taken as the minimum. Under maximum conditions of tightness, etc., to obtain 85 lb. per square inch compression the cylinder clearance can be 35 per cent of the piston displacement. All the pressures given above are in pounds per square inch absolute.

Shipping Weight of Packard Twin-Six

Editor THE AUTOMOBILE:—What is the shipping weight of the Packard twin six?

2—What is the fuel consumption of these cars at 20 m.p.h.? What compression do they use? What is the tire and fuel cost per mile?

3—How does the progressive gearshift lever engage its gears? How does the H quadrant lever select its gears?

4—Please show the mechanism which make its impossible to shift gears while the clutch is engaged?

5—What is the correct pronunciation of Renault, Goux, Boillot, Bleriot?

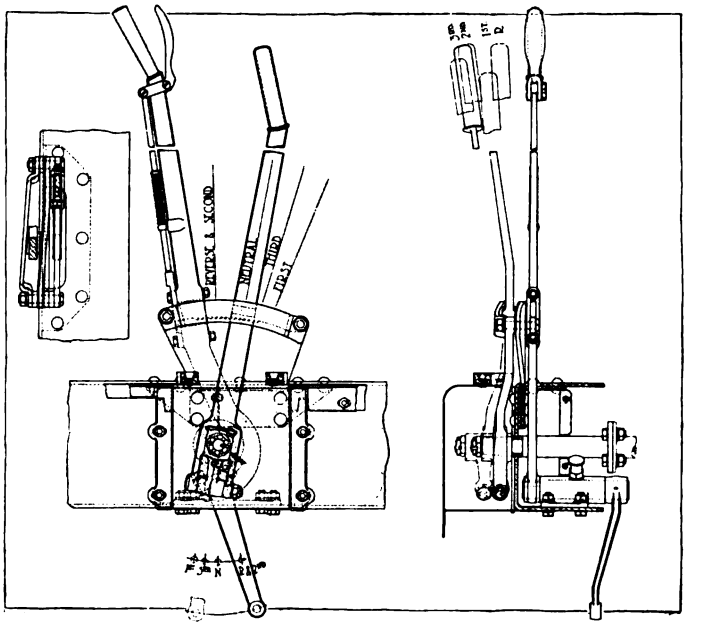
Mount Sterling, Ohio. C. W. S.

—The model 1-25 seven-passenger car complete with full liquid supplies and two spare tire rims weighs 4500 lb. The model 1-35 seven-passenger car with full liquid supplies and two extra tire rims weighs 4590 lb.

2—The fuel consumption at 20 m.p.h. is approximately 12 miles to 1 gal. The compression used is from 75 to 78 lb. The tire and fuel cost per mile will depend on the individual driver and the country.

3—Progressive gearshift levers engage their gears in the order 1, 2, 3, 4 or 4, 3, 2, 1 while with the H quadrant or selective gearsets the gear desired can be selected at will.

4—There is no such mechanism as this on the Packard twin six. The gearshifting arrangement employed in this car is shown in the accompanying illustration Fig. 3. In case you would be interested in the gearshifting lever system employed in the Packard twin six, THE AUTOMOBILE is showing Figs. 1 and 2, two assembly drawings of the mechanism. You will note that the gearshift lever is of the selective side rocking type. The shifter finger which engages the gearshift rods in the transmission case, is made with an auxiliary portion carrying a face cam which runs between two rollers mounted in a lateral sliding plunger in the transmission case beneath the gear shifter rods. This plunger has a slot in its upper side adapted to register with whichever of the gear shifter rods is engaged by the gearshifter lever. The other gearshifter rod is consequently positively locked against any movement, and it is also impossible to move both gearshifter rods at the same time.



Figs. 1 and 2—Two assembly views of gearshifting lever arrangement used in the Packard twin six

One of the rollers pressing on the face cam on the gearshifter lever is carried in a plunger backed up by a heavy, coiled spring. The face cam has a notch for neutral position and has a fairly steep cam action down each side which assists in shifting into any gear once the change speed lever is moved forward or back out of the neutral notch. In addition to this assistance to gearshifting given by the cam and spring controlled roller, the cam is also formed to produce a lock to hold any one of the gears when engaged in its normal running position.

The travel of the gearshifting rods fore and aft, is regulated by adjustable stops at the ends, and when any gear is engaged it is retained in position by the shifter rod being held against its stop through the shifter lever face cam and the spring-controlled roller.

5—The correct pronunciation of Renault is Ren'-olt; Goux, Goo'; Boillot, Bwah'-lo; Bleriot, Bler'-ee-oh.

Blown Fuse Due to Shorting

Editor THE AUTOMOBILE:—I have a Saxon six touring car equipped with a Gray & Davis starting motor. When running at a speed of 15 m.p.h., or over, the generator generates too much current. The automatic cutout does not work, and the 20-amp. fuse is burned out. Please advise why the

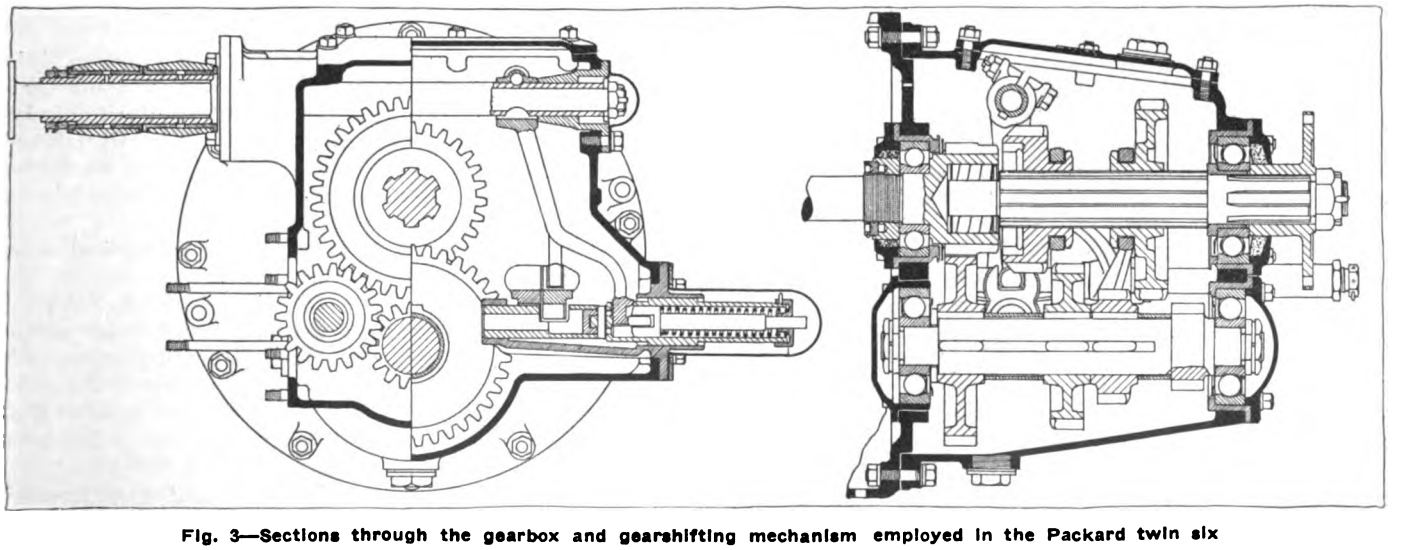


Fig. 3—Sections through the gearbox and gearshifting mechanism employed in the Packard twin six

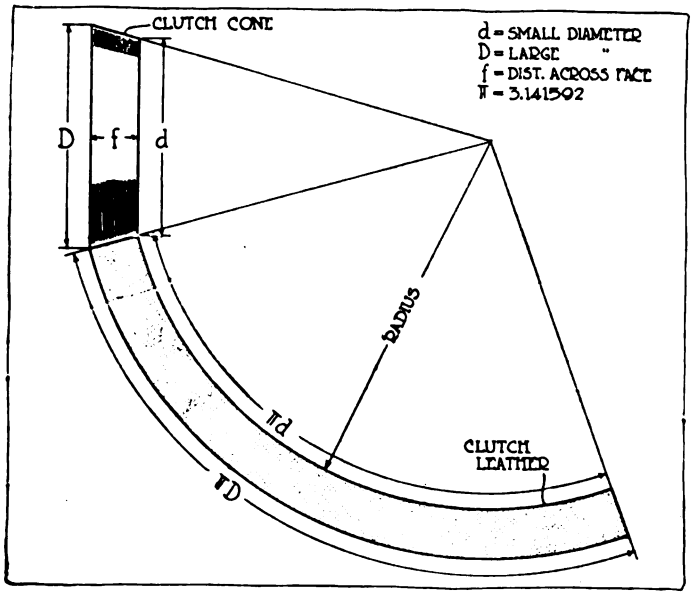

Fig. 2—Method for laying out leather for a clutch cone

generator generates too strongly and if the trouble in the cutout is in the adjustment.

2—Who manufactures the rear axle for this car?

3—What is the make of engine?

4—What makes a grinding sound when the engine is pulling hard? Is it the clutch slipping?

Weston, W. Va. C. J. L.

—The fuse on this car is rated at 30 amp. instead of 20 and is designed to carry 30 amp. and blow at about 50 amp. For this reason it is quite impossible that the generator could burn this fuse when running. The cause of this fuse blowing is either a short-circuit in the wiring or possibly the horn circuit or because the cutout has failed to open when the engine stopped. The cutouts are set properly and sealed before they leave the Gray & Davis factory and the guarantee in the instrument is revoked on the breaking of the seal by the customer. It is therefore recommended that this apparatus be taken to the nearest Gray & Davis service station or return it to the Gray & Davis factory in Boston, Mass.

2—The rear axle is manufactured by the Timken Detroit Axle Co., Detroit, Mich.

3—The motor is made by the Continental Motor Mfg. Co., Detroit, Mich.

4—The grinding noise you mention can probably be traced to the starter chain.

Laying Out Cone Clutch Leather

Editor THE AUTOMOBILE:—Please give me a diagram illustrating the most practical way to lay off a piece of leather for a cone clutch, knowing the largest diameter, the smallest diameter and the distance across the face of the cone.

2—In applying a new leather to the clutch, is it correct to soak the leather in oil and if so, before or after applying same to the cone?

3—What limits the distance apart the points of a spark plug may be set and the electrical reason for same?

4—What is the distance from edge of the float chamber to the surface of gasoline when same is at the correct level in a 1¼-in. carbureter.

5—The model 10, 1910 Buick comes regularly equipped with a 1½-in. carbureter, and in the event that a Holley carbureter was to be substituted, what would be the proper size to use?

6—Would increasing or decreasing the taper of the needle point in the jet of a carbureter, affect the mixture allowing that the same amount of gasoline passes in each case?

7—What means are used to take the back lash out of bevel gear in back axle of 1910 model 10 Buick?

Cheriton, Va. H. S. A.

—The diagram showing the method for laying out a piece of leather for a clutch cone is shown in Fig. 2. The largest diameter is signified by D, the smallest diameter by d and the distance across the space by f. The character π is equal to 22/7 or 3.14.

2—Before working the leather soak it in neat's-foot oil.

3—The distance between the points of the spark plug is set to secure the maximum efficiency. The current is capable of jumping a certain gap. At the extreme dimensions of this gap, the spark will be thin and weak, at the minimum dimensions the spark will be intense but short. A mean is adopted to provide a thick spark of reasonable length.

4—The level is such that the gasoline is 1/16 in. below the fuel nozzle.

5—A carbureter of the same size should be used.

6—The taper on the metering pin will affect the mixture as it governs the distribution of the section, a certain proportion of which falls on the gasoline jet and the remainder on the air intake.

7—No adjustment was provided on the rear axle in the model 10 Buick. The only method by which you can correct the mesh of the ring gear and pinion is to insert washers or shims behind the thrust bearings. This must be done while the axle is disassembled, and proper mesh is very largely a matter of trial and error.

Oxygen Flame Not Harmful

Editor THE AUTOMOBILE:—I shall be greatly obliged if you will advise me of your opinion as to the desirability of removing carbon by the oxygen flame method. It will be of interest to know whether, aside from the convenience of the method, it is even remotely harmful to the motor or likely to cause warping in the valves. I have followed your inquiry department, but have seen nothing bearing directly on this question in which I have no doubt, many motorists are interested.

Brooklyn, N. Y. P. S. CLARKE.

—No harm will result from removing the carbon by the oxygen flame method. When this is done the piston of the cylinder which is being operated upon should be at top dead center to be sure that the carbon is removed from the piston head. The temperatures within the cylinder are not near what they are in actual operation of the motor and although it is true that the water in the circulating system is not in motion, the temperature reached in burning out the carbon is not sufficient to do any harm.

Piston Displacement of 4 by 6 Four

Editor THE AUTOMOBILE:—Will you kindly explain through THE AUTOMOBILE what, and how obtained, the compression space will be for a 4 by 6-in. stroke four-cylinder motor with 90 lb. compression, cold. After stating the cubical contents of the compression chamber, will you also work this out so that I may study same carefully to familiarize myself with it?

2—Please explain what is meant by the mechanical compression ratio.

New York City. A. W. W.

—The piston displacement of a 4 by 6 four-cylinder motor is 301.6 cu. in. For one of the cylinders, the displacement is 75.4 cu. in. The relationship between the volume of the combustion chamber and 75.4 cu. in., therefore, must be such that when the piston is at the top stroke the pressure in the combustion chamber is 90 lb. per square inch absolute.

There are two methods by which a gas can be compressed and expanded. One is known as the adiabatic method in which no heat is either abstracted from or given the gas.

The other is the isothermal method in which the gas is kept at a constant temperature due to the use of water jacketing. The conditions in a gasoline engine cylinder are somewhat between adiabatic and isothermal. Therefore, these two conditions may be taken as extremes and the proper volume for the desired displacement will be somewhere between the two limits secured by calculation on adiabatic and isothermal bases.

Taking adiabatic first, the formula which air follows when compressed is

$$PV^{1.4} = P_1V_1^{1.4}$$

Let $P = 14.7$ lb. per square inch or atmospheric pressure.

$V = (75.4 + V_1)$ = Displacement plus compression volume.

V_1 = Combustion chamber volume, the unknown quantity.

P_1 = The compression pressure or 90 lb. per square inch absolute.

Then the equation becomes:

$$14.7\ (75.4 + V_1)^{1.4} = 90\ (V_1)^{1.4}$$

$$\frac{90}{14.7} = \left\{\frac{75.4 + V_1}{V_1}\right\}^{1.4}$$

Taking the 1.4 root of each side of the equation we have

$$\frac{75.4 + V_1}{V_1} = \sqrt[1.4]{\frac{90}{14.7}}$$

Solving, $V_1 = 29$ cu. in.

Taking the isothermal equation,

$P\,V = P_1\,V_1$ and substituting the equation becomes

$14.7\ (75.4 + V_1) = 90\ V_1$

solving $V_1 = 14.7$ cu. in.

The required combustion volume will therefore be somewhere between 15 and 29 cu. in., or perhaps 22 cu. in.

2—By mechanical compression ratio is meant the ratio of the cylinder volume to the combustion chamber volume.

Motor Made by Garford Co.

Editor THE AUTOMOBILE:—Some time ago I purchased a motor for installation in a boat and since I now desire to add an electric starting and lighting system, I find it necessary to have some data concerning the speed, gear ratios, etc.

The motor was taken from an old Studebaker roadster, and I understand it was made by the Garford Co. The cylinders are four in number, supposed to be 4¾ by 5, cast in pairs. Crankcase is of aluminum, with four supporting lugs, flywheel at after end, bored for cone clutch; fitted with Remy high-tension magneto and centrifugal water-circulating pump.

1—Can you tell me whether such a motor was made by the Garford company?

2—Has THE AUTOMOBILE published at any time the horsepower and torque curves of this type of motor?

3—Can you give the formula by which the horsepower of electric motors, necessary for cranking this motor, can be calculated?

4—Please show the wiring diagram for the Remy high tension magneto; the proper disposition of the cable containing three conductors, red, black and yellow. This is not understood.

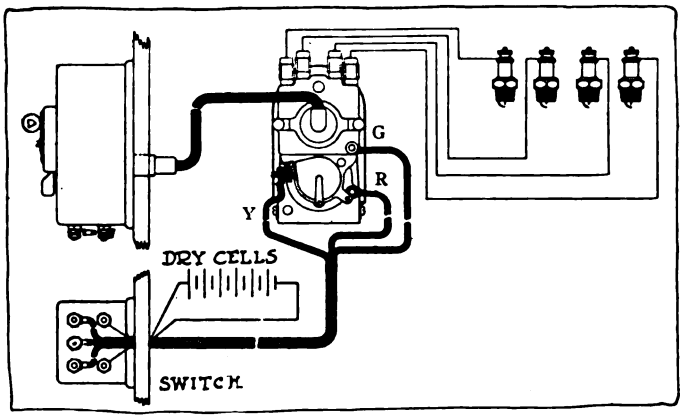
Brooklyn, N. Y. J. F. K.

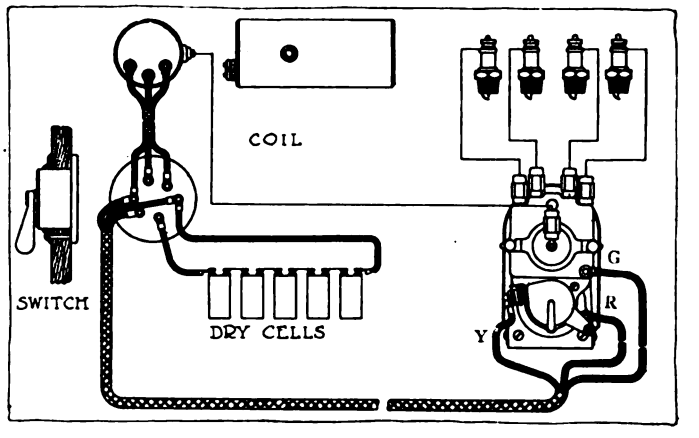
—The motor you describe was doubtless made by the Garford Co. as the bore corresponds to their motor, but the stroke is 5¼ and not 5 in. The Garford company fitted this with a Bosch low-tension magneto.

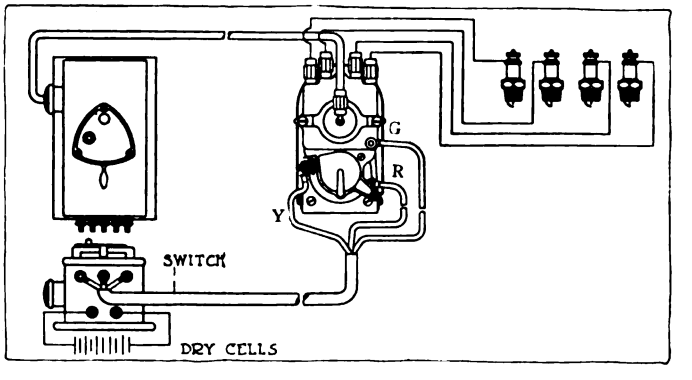
2—No.

3—This will depend on the speed at which you wish to crank it. If the pull, for instance, is 50 lb. to crank it at an arm length of 10 in. the energy necessary is 500 lb. in. or about 43 ft. lb. If it is necessary to exert this through a distance of any given amount it is easy to measure the power necessary in terms of foot pounds per minute. The number of foot pounds per minute divided by 33,000 will give you the horsepower of the motor required for cranking the engine.

4—The Remy Magneto Co. has been in business for about seventeen years and during that time has manufactured many different types of what are commonly known as high-tension magnetos. This concern, however, has never placed upon the market a strictly high-tension magneto, but has used the type in which the current is stepped up in a separate transformer coil. A few typical illustrations of Remy installations are given in Figs. 3 to 5 and you will note on practically all the coils the terminals are marked Y, R and G, standing for yellow, red and green, so that the person using them would know how to wire the coil. As a rule the connections on all the magnetos are the same, that is, the green wire is connected to the live terminal of the magneto, the yellow wire to the circuit breaker and the red wire to the ground terminal.







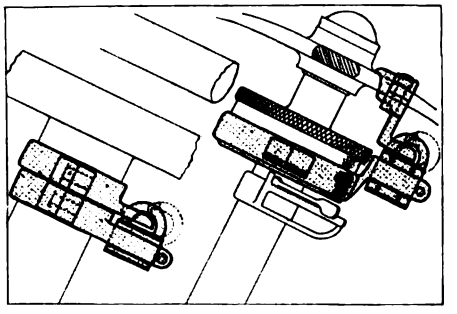
Figs. 3, 4 and 5—Typical Remy high-tension magneto wiring diagrams

ACCESSORIES

Deitz Steering Wheel Lock

THIS is a simple device for locking the steering wheel. A special design being made for Fords, and a different model for other cars. The general model consists of two metal clamps for the steering post, with a small padlock firmly bracketed in the lower clamp and three attaching rings as a part of the upper clamp. This arrangement provides for locking the steering post whether the car is standing with the wheels set straight ahead or whether it is left in such a position that the steering wheel is turned to the right or left. This makes the device easy to use if the car is driven up to the curb and left hurriedly without squaring the position of the wheels. The Ford model is similar in working principle, but here the upper clamp is fastened directly to an arm of the steering wheel. For locking in different positions, this model must depend upon three lock brackets on the lower clamp.

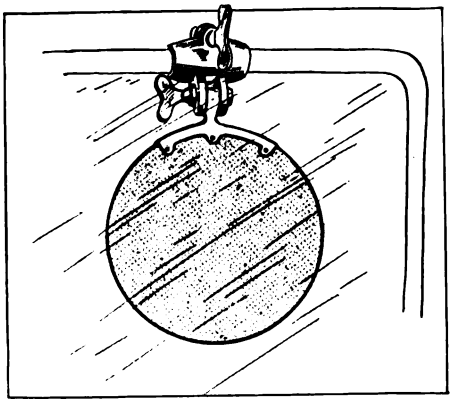
These clamps can be made of either forged steel or hard bronze, and are fastened by a patent device which will prevent removing them with a screwdriver or any ordinary tool. A small spring holds the bar of the padlock in the clear when open, thus guarding against its being jarred shut and catching the clamp which turns with the steering wheel. The device sells for $2.50.—Henry Deitz, Denver, Col.



Deitz steering wheel lock in two models

Staude Glare Stopper

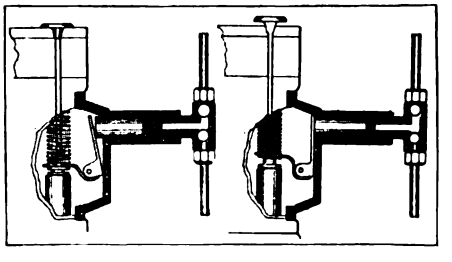
A disk of heavy glass, of an amber color, is clipped to the edge of the windshield in such a position that the driver of the car can look through it by moving his head a little to one side, when facing the headlights of an approaching car. The clip incorporates a joint which permits the glare stopper to be kept vertical even when the windshield is inclined. If the glass is broken it may be replaced for $1.25.—The glare stopper sells for $2.50. —E. G. Staude Mfg. Co., St. Paul, Minn.



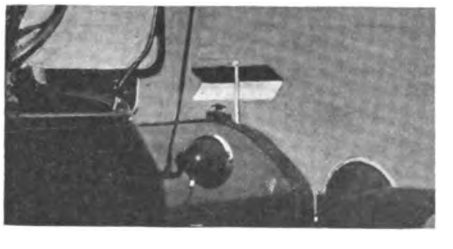
Staude glare stopper on windshield

Strong Oil Pump for Fords

A plate carrying the Strong oil pump fits over the valve stem compartment of the Ford motor, in place of the regular cover plate. The pump is of the plunger type and is actuated by a rocker arm, one end of which is in contact with one of the valve lifters; the lifter raises the arm and pushes the plunger outward, discharging the oil in the barrel, and on the return stroke the plunger is brought back by a spring and sucks in a fresh charge. The oil is pumped from the bottom of the flywheel housing through a sight feed on the dash and forward to the timing gear housing from which it goes into the crankcase under the connecting-rods and is splashed. The makers state that the pump can be installed in 20 min. It sells for $5.—Perkins Mfg. Co., Des Moines, Ia.



Strong plunger oil pump for Ford cars



Kruse direction signal on car

Kruse Signal

The Kruse mechanical signal indicates both in front and behind the car which direction a motor car intends to take at a street intersection. It consists of two signal arrows, in regulation red and green, mounted upon nickeled steel rods, which are turned by a cable passing around a pulley at the base of each rod and controlled by a lever attached to the steering post. This lever runs down alongside the post to a universal joint at the floor of the car, where it connects with the cable. The front signal stands above and in front of the radiator cap, while the rear one is fitted to a bracket midway between the springs and near the tail light.

The device is simple in construction, easy to operate, made to fit any style of machine, and can be adjusted to prevent rattling or getting out of order. Being operated mechanically, there is no upkeep expense for batteries or lights.

The position of the two signal arrows is such that the front one is well lighted at night by the side lights on the car equipped with the device, while the rear arrow is made clear either by the tail light or by the headlights of any car following at all closely. The signal sells for $10.—National Auto Signal & Mfg. Co., Denver, Col.

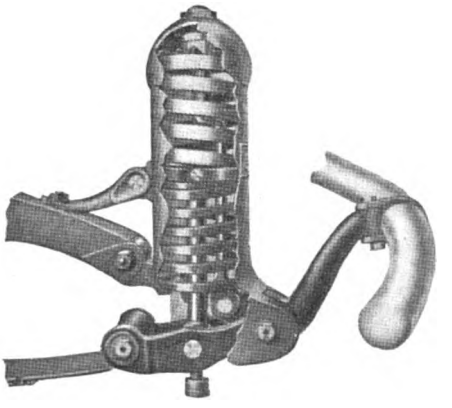
Answer Spark Plug

A spark plug which the owners claim will not break, leak, soot or oil soak has been brought out under the name of the Answer. It is made in every size including ½-in. standard, ½-in. extension, ⅞ S. A. E., ⅞ extension, metric and Ford. There is also a metric motorcycle size. The plug is shown in section herewith and, as will be noted, there is a steel spindle which acts as the core of the plug. Surrounding this is mica insulation 3/32 in. thick. The shell is made in all sizes and the terminal is a combination design suitable for screw cap connection or snap-ons. The price of the plug is $1.—Hill Mfg. Co., New York City.

U. S. E. Shock Eliminator

The U. S. E. shock eliminator and bumper combined is a mechanical device which is attached between the frame of the car and the springs. It consists of a metal casing in which are assembled spiral springs having between them a reciprocating trunnion ring attached to

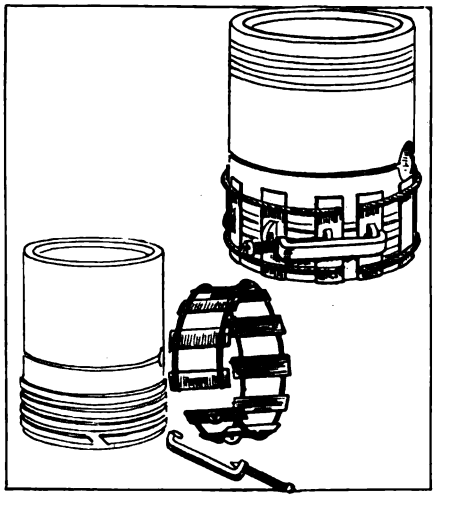
the main connecting-rod. This connecting-rod, being joined to the lever which is pivoted at one end of the shock absorber and at the other end to the car spring, receives the force of the shock from the car spring and transmits it to the spiral springs of the shock eliminator where it is absorbed by their reciprocating action. The bumper, which is a part of the front U. S. E. shock eliminator, is connected with the internal spring so that any blow received by the bumper is absorbed by their action. The prices are: Front pair, including bumper, $60; rear pair, $50; rear pair, underslung, $40; small car equipment, $80, and for attaching complete, $10.—Universal Shock Eliminator, Inc., New York City.



U. S. E. combined shock eliminator and bumper

Morgan Piston Ring Tool

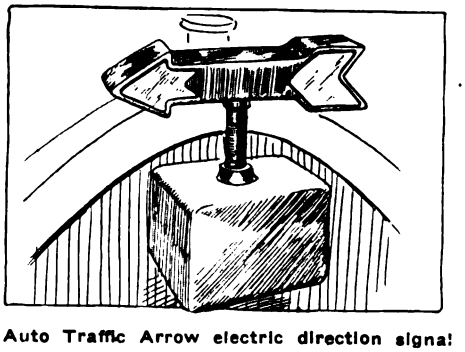
In this tool a series of flat steel bars are connected together by two flexible steel cables, the last bar on one end and several of the bars on the opposite end being fitted with lugs. The device is wrapped around the rings of a piston and a small clamp, which is furnished with the tool, is placed on the two lugs which are the right distance apart and screwed up until the rings are well down. When the piston is inserted in the cylinder the device is pushed off the rings as they enter the cylinder in succession. This tool sells for: 2 to 4-in. pistons, 50 cents; 3 to 5-in. size, 75 cents, and 4 to 6-in., $1.—Morgan Mfg. Co., Newport, R. I.



Morgan's piston ring compressing tool

Auto Traffic Arrow Signal

To indicate by day or night to other vehicles, pedestrians or traffic officers the direction to be taken or the intention of stopping, a traffic signal under the name of the Auto Traffic Arrow is marketed. The outfit consists of two metal motor boxes, one secured to the top of the radiator and the other at the rear. From the mechanism in each box an inclosed shaft extends upward and upon this is mounted an arrow finished in highly polished nickel. Within these arrows are powerful miniature electric lamps which illuminate them at night, indicating plainly by night or day the direction which is to be taken.



Auto Traffic Arrow electric direction signal

The action of both front and rear arrows is controlled by a set of three buttons clamped to the steering wheel or post or anywhere desired. A touch of the button is sufficient for the operation of the arrow and it is not necessary to hold the button down as the arrows remain locked in position until one of the buttons is again pressed.

Both arrows turn simultaneously when the corresponding button is depressed for right or left. In addition to the arrow in the rear of the car there is also a disk which is illuminated at night and when the driver presses down upon his brake to bring the car to a stop the disk makes a half turn showing the word, Stop. When the brake is released the disk turns back to its original position.—The Auto Arrow Signal Co., St. Louis, Mo.

Benn Power Tire Pump

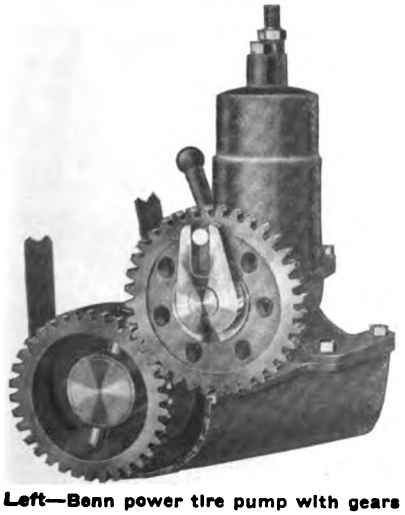
This is an all-metal pump with steel crankshaft in one long bearing. The connecting-rod is of bronze and cylinder and piston of gray iron. The pump is permanently attached, brackets and driving gears being provided to suit various motors. The makers state that the pump for Fords will put from 45 to 60 lb. pressure into a tire in 1 min. The construction is exceedingly simple and compact. There is an asbestos oil separator which will last a year or two before requiring renewal. Standard type $8, Ford type $7.—Benn Pump Works, Boston, Mass.

Kumpy Jitney Bus Sign

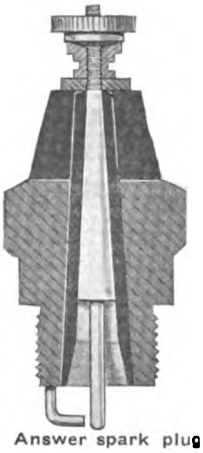
An illuminated sign giving the destination of the jitney buses is one of the early accessories to appear in connection with the movement toward the low-priced transportation medium. They are similar to the direction signs on street cars, having a roll of canvas or duck on which are painted the destinations of the jitney. The roll is inclosed in a box with a glass front, through which the destination is visible. The sign is equipped with two 12-volt lights, which are supplied with current from the battery on the car. The required destination can be placed in front of the glass by simply turning a crank, and the sign itself can be mounted on the windshield if desired. The signs sell for $5.—Walter Odell, Kansas City, Mo.

Shanhouse Motor Suit

The Shanhouse is a one-piece slip-over suit of olive khaki, designed to protect the clothing when working about the car. It can be donned quickly and easily and covers the clothing completely and has no flapping ends or corners. The suits sell for $2.50 each.—W. Shanhouse & Sons, Rockford, Ill.

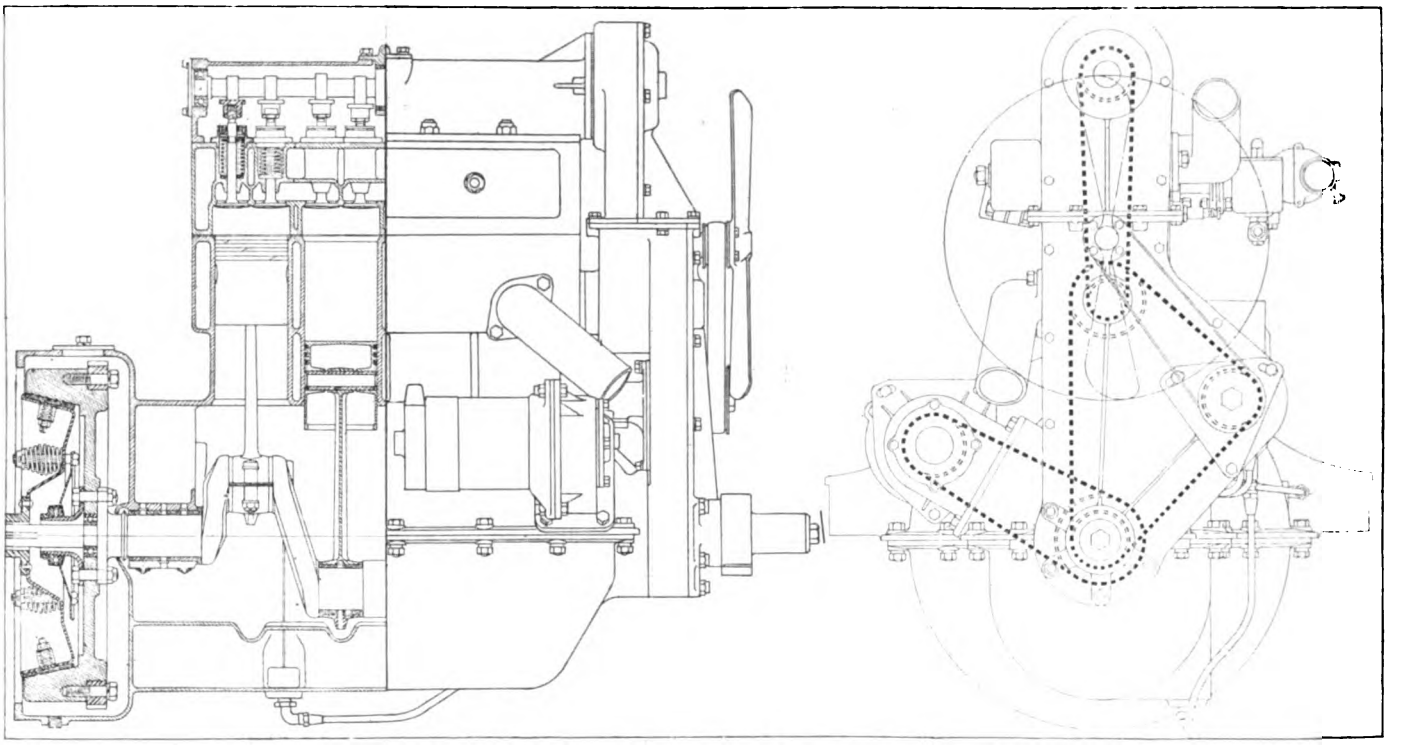


Left—Benn power tire pump with gears and clutch. Right—Section



Answer spark plug

Overhead Valves in Farmack Four



Left—Four-cylinder block motor used in Farmack car. Right—End view showing chain layout for overhead camshaft drive

THE Farmack car is made by the Farmack Motor Car Corp., Chicago, Ill. This is a new concern headed by A. J. Farmack, formerly of Detroit, who is president and general manager. The car appears in three body styles on a single chassis, a roadster and a five-passenger touring car at $855 and a cabriolet at $1,155.

The car has a wheelbase of 112 in., a four-cylinder block 3½ by 5 in. motor, 33 by 4 in. tires.

The feature of the Farmack car is the overhead valve, overhead camshaft motor. As will be seen from the illustration of the motor, the valves are directly in the head of the cylinder and are operated by a camshaft above them and whose cams push directly on the valve stems or extensions of the valve stems. The camshaft is operated by a chain drive which is a two-stage drive, the first stage being a triangular chain around sprockets on the crankshaft, magneto and an idler. A secondary chain from the idler to the camshaft sprocket carries the drive to the latter.

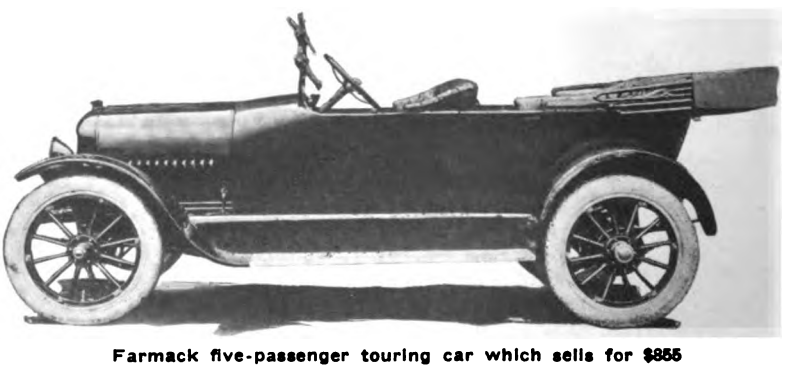
Accurate adjustment of the timing of the camshaft drive is provided by an arrangement at the sprocket end of the camshaft by which the camshaft is driven from its sprocket through a tooth clutch which permits the adjustment to be varied to as close limits as one-tenth of the width of a gear tooth instead of the smallest adjustment being the width of a gear tooth as would be the case without this subdivision. The valve stems are provided with an adjustment for wear and the contact points of the cams are of the mushroom type, both of which features are designed with the idea of eliminating noise. The tungsten steel valves are 1 3/16 in. diameter with a lift of ¼ in. The motor can be divided into four parts, first the crankcase which is split horizontally; second, the cylinder block; above this the cylinder head carrying the valves; and above this the camshaft with its cover. The crankshaft has two bearings, 2 by 2¾ in front and 2 by 3½ at the rear, bronze backed and babbitt lined.

The lubrication system combines a splash system with the level maintained by a plunger pump. This pump supplies oil directly to the camshaft chamber and to the camshaft bearings, the entire chamber being flooded with oil. An overflow from the top of the motor carries oil down to the splash troughs into which the connecting-rods dip.

Cooling is by thermo-syphon and the electric system is Bijur two-unit with Willard battery and battery ignition.

From the engine power is transmitted through a cone clutch with spring inserts and this has an arrangement for adjustment. The three-speed gearset is made by the Grant-Lees company and uses New Departure bearings throughout. From this the drive is taken through an inclosed propeller shaft with a universal joint immediately back of the gearset. This is supported on the yoke, the drive being carried through three-quarter elliptic springs. The rear axle is floating.

The braking system includes internal and external brakes on 1¾ by 12-in. brake drums, tires are 33 by 4 in. and non-skid in the rear on demountable rims.



Farmack five-passenger touring car which sells for $855

Standardizing Pistons

THE suggestion to adopt a standard formula for piston design, or to set up a range of standard pistons covering practically all automobile requirements, needs rather more consideration than have most of the existing S. A. E. standards. A standard to be a good, useful and efficient thing must benefit everyone. The piston standard would certainly cheapen pistons, because it would convert them into a specialized product instead of being an individual one, as they now are. Standard ring sizes would help a business that is already highly specialized and, most of all perhaps, the dealer would feel the benefit because his stock of spare pistons and rings could be reduced enormously. The owner, coming last in the chain, would obtain indirect benefit.

But, and now comes the big question, is it possible to standardize pistons while they are in a state of evolution?

This year piston design has been entirely changed by the coming of aluminum alloys which will withstand the conditions, and the case is further complicated by the many patterns of special rings which are now in competitive, experimental use. Thus, it appears that any standard will have to be experimental also. To make the attempt is good, but it should be made with due caution, for the case is so different that past experience of the benefits of simple standards is not fully informative.

Gas-Electric Progress

AN event of 1915 which should not be allowed to pass without due recognition is the successful marketing of a gas-electric passenger automobile. Despite many attempts in the past, it has been left to America in the present year to manufacture in a standard form a passenger car without gear connection between the engine and the road wheels.

Of course, this particular machine is being manufactured on a small scale only, but it has sold in a quantity sufficient to prove the existence of a market, and it is more than probable that the demonstration of ability thus provided will lead to the production of gas-electric passenger cars on a far larger scale.

There are as many types of electric and semi-electric transmissions as there are kinds of gasoline motors, so the possibilities for development are vast, but just as quantity output has made the ordinary automobile what it is to-day, so will quantity have to exercise its influence before the gas-electric car settles into a standard form.

It is inconceivable that the success of the first *commercial* essay with a vehicle of this type will not be followed by larger scale manufacture, and early experiments in this connection are to be anticipated.

Electric Steel

IN spite of the contrary opinion of many it cannot be doubted that the majority of metallurgists in this country welcome the growth in the use of electric furnace steels. With the constant wish to be always seeking something better in the way of materials, it is but natural that a process which increases the good qualities of steel should be welcomed. True, in the present state of development steel made by this process costs more; but it can hardly be doubted that the general adoption of the product for parts which are subjected to puzzling stresses of a dynamic nature would greatly lower the price.

In buying any grade of material first cost alone should never be considered, and even while the price of the electric furnace steels remains above that of the open hearth products, it would be well for the manufacturer who is obliged to scrap a high percentage of parts upon which high machining costs are placed, to consider the advantages of the more expensive but more uniform and purer product.

In this great industrial country it has been estimated that we use approximately the same quantity of electric furnace steel in one year that Germany does in a month.

The war also has had its influence. While we imported thousands of tons of electric furnace steel before the conflict started, the supply has now been shut off with the result that the steel is being made here. This increased production is the very factor needed to reduce prices, and there are many who believe that increased production, combined with the lower wastage factor, will rapidly bring to the front the purer and more uniform product.

$15,000,000 Overland New Pref'd

7% Stock Convertible into Common at $300 Per Share—$50,000,000 Common

NEW YORK CITY, Nov. 10—The Willys-Overland Co. yesterday announced an issue of $15,000,000 new convertible 7 per cent preferred stock which will be offered to holders of the common stock of the company at 102½, with adjustment of accrued dividends. Common stockholders of record Dec. 21 and also preferred stockholders will have the privilege of subscribing to the new stock to the extent of 71½ per cent of their respective holdings. The new preferred stock, of which the authorized issue is $25,000,000, is convertible from Jan. 1, 1917, up to Jan. 1, 1922, into common stock at $300 a share. The present issue of preferred, of which there is $4,483,700 outstanding, will be called for redemption at 110 and accrued dividend on or about Jan. 13 next. President Willys, being desirous that the holders of the present preferred shall have an opportunity to continue their interest in the company, has agreed to waive part of his subscription rights as holder of common stock, those rights to go to the holders of present preferred who may subscribe on the same basis as the holders of common stock.

The new preferred issue has been underwritten. A special meeting of stockholders will be called on or about Jan. 14 to authorize the new stock. The authorized amount of common stock will be increased from $25,000,000 to $50,000,000 of which a par amount sufficient for the conversion of the $15,000,000 new preferred will be reserved for effecting the conversion thereof. The present amount of common stock outstanding is $21,000,000 and $1,500,000 additional common is to be set aside for sale to employees.

Redeemable at 110

The new preferred stock is redeemable at 110. It is provided that the remaining $10,000,000 of the $25,000,000 authorized may be issued from time to time, but not before Jan. 1, 1917, for cash, provided the net quick assets of the company immediately upon the issue of this stock shall be equal to 110 per cent of the amount of preferred stock outstanding. The remaining preferred may be issued in series and the stock of different series may be at dividends at the same or a lower rate, may be redeemable at a lower price, and may be nonconvertible or convertible at higher prices for the common than those provided for the $15,000,000 issued at this time.

Subscription to the new preferred stock will be made as follows: Jan. 21, $40; Feb. 10, $30; March 1, $33.23. These payments include adjustments of accrued dividends. Subscriptions may be paid in full on Jan. 21, in which case the amount payable will be $102,889 per share, including adjustment of accrued dividends.

To Retire Present Issue

Out of the proceeds of the $15,000,000 new preferred, the present issue of $4,783,000 preferred will be retired and the balance, about $10,500,000, will be applied to the general funds of the company.

Applications will be made to list the new preferred stock and the subscription receipts on the New York Stock Exchange.

In connection with the proposed new issue a circular has been sent to stockholders showing that the company's earnings for the nine months ended Sept. 30, 1915, were over $8,500,000 of which approximately $3,500,000 was earned in the three months ended Sept. 30, 1915. These earnings compare with $5,231,274 for the year ended June 30, 1914, and $3,019,098 for the six months ended Dec. 31, 1914. The net current assets at the present time plus the net amount to be realized from the new financing are approximately one and one-half times the amount of the proposed $15,000,000 preferred stock issue and the total net assets exclusive of good will, etc., on the same basis about two and one-quarter times the proposed issue.

Will Keep Lozier Property

DETROIT, MICH., Nov. 9—The Associated Lozier Purchasers who took over the assets of the old Lozier Motor Co. for $1,000,000 and who had the privilege of re-selling the property, consisting of the plant and land in Detroit, have notified the Detroit Trust Co., trustee, that they will keep the property. An agreement has been made whereby the price of the plant property or $225,000 will be paid in four yearly installments of $50,000 and one of $25,000 beginning Feb. 15, 1916, and on the same date of the following years, while the payment of $125,000 for the vacant land property is to be made in five annual installments of $25,000 on the same dates.

The Associated Lozier Purchasers have paid up to Oct. 15, 1915, $449,906.15 of the total purchase price of $1,000,000. The trust company has thus far paid two dividends of 5 per cent to the creditors, on allowed claims.

—

National Tube Advances Prices

PITTSBURGH, PA., Nov. 5—The National Tube Co. has advanced prices for tubing, casing and drive pipe about $2 a ton.

Plath Maxwell Sales Manager

Stebbins in Charge of Executive Sales Work in Detroit —Other Promotions

DETROIT, MICH., Nov. 4—Some important promotions have been made in the sales organization of the Maxwell Motor Co., John J. Plath, who was supervisor of sales zone No. 1, with headquarters in New York, has been appointed sales manager of the Maxwell company. Mr. Plath has been with the company for over one year, being previously connected with the Colwell Lead Co., New York and Windsor, Ont.

C. E. Stebbins, who was superintendent of sales and assistant sales manager, has been promoted to have full charge of all executive sales work at the Detroit headquarters of the company.

C. R. Newby, L. K. Cooper and T. J. Toner, zone supervisors, have been attached to the general national sales staff.

The staff of zone supervisors is now as follows: L. F. Smith, Boston; E. W. Clarke, New York; H. H. Howe, Pittsburgh; J. P. Headley, Atlanta; E. M. Lubeck, Chicago; C. S. Riedel, Minneapolis; E. F. McConaha, Indianapolis; W. C. F. Morris, Memphis; G. E. Clarke, Kansas City; L. A. Smith, Dallas, Tex.; W. J. LaCasse, Portland, Ore.; E. E. Thompson, San Francisco.

Acceptance Corp. Will Buy Notes Taken by Truck Dealers

NEW YORK CITY, Nov. 6—A new credit department has been opened by the Acceptance Corp., 55 Liberty Street, this city. Under the new plan a dealer can now accept notes in part payment for a truck which the corporation agrees to purchase from him. This enables the dealer to pay the truck maker cash for his product and permits the dealer to get the concessions, discounts and freight allowances usually made to cash customers. It will also relieve him of the bother of collecting the notes from the customer or financing any part of the transaction.

This corporation started business in 1909 and includes in its board of directors R. M. Owen, R. A. Rainey, R. H. Montgomery, E. D. Bird and D. B. Mills.

—

Lakey Leaves Foundry Co.

MUSKEGON, MICH., Nov. 5—Vice-president and general manager William B. Lakey, of the Lakey Foundry & Machine Co. has resigned to give all his attention to the Pressed Steel Co. which he organized recently. This concern occupies the building formerly used by the Muskegon Pattern Works.

To Investigate Export Trade

Federal Trade Commission To Send Out Letters of Inquiry for Referendum

WASHINGTON, D. C., Nov. 6—In the near future the Federal Trade Commission will send out to the automobile and supply manufacturers a letter of inquiry, followed up by a brief schedule, as a part of the investigation of conditions that affect American foreign trade. Congress has empowered the commission to make an investigation and to report the facts with such recommendations as it deems advisable.

It is pointed out that the war in Europe has so affected the trade of the world that American enterprise has a peculiar opportunity to supply the wants of foreign markets and to secure a greatly enlarged share of their trade. The commission, therefore, deems it to be its duty to complete with all possible dispatch an investigation which may assist Congress in determining what action may be required in the public interest for the promotion of American foreign trade.

By public hearings throughout the country and by other means the commission has been gathering facts and information as a basis for its report to Congress. It now wishes to obtain information from a large number of men who were unable to appear at the hearings. For this purpose these letters and schedules will be sent out.

30,000 Letters to Go Out

About 20,000 letters will go to American manufacturers and producers and about 10,000 will be sent to other authorities on foreign trade conditions, such as export commission merchants, manufacturers' export agents, importers, domestic merchants, publicists, lawyers, economists, bankers and engineers.

A return post-card accompanying the letter is designed to give the commission a broad "yes" or "no" referendum on the advisability of export combinations and to put it in touch with those who are willing to assist the commission by furnishing further facts and suggestions. To those who state that they will co-operate with the commission in furnishing facts, etc., the schedule of inquiries will be sent, covering the topics on which the commission desires information.

The 20,000 names of manufacturers and producers include every important branch of American industrial enterprise and represent every shade of opinion in regard to the present problems of our foreign trade.

The 10,000 other persons to whom the letters of inquiry will be sent include even greater diversity of interest and thought. By obtaining facts and suggestions in this manner from a large number of persons with different experiences and points of view, the commission expects to secure a great deal of valuable information.

In its work the commission will also receive assistance from the Department of State and other government offices.

Argo Motor Co. Buys Standard Electric Plant

JACKSON, MICH., Nov. 6—A deal has been completed whereby the Argo Motor Co. has acquired the plant and land of the old Standard Electric Co. which it has been occupying. It is expected that arrangements will be made to enlarge the manufacturing facilities of the company, it being contemplated to build between 20,000 and 30,000 Argo cars for the season of 1916.

In connection with the contemplated expansion move it is announced that the Jackson Motor Parts Co. has been organized and incorporated. Its capital stock is $210,000. This concern will make principally parts for the Argo cars, but, it is said, will ultimately also make parts for the general trade. L. E. Latta, vice-president and general manager of the Argo company, has been appointed president and general manager of the new parts company. L. E. Wilson, Chicago, is now managing the Argo business and Stanley Whitwarth, Indianapolis, has become production manager.

Pettit and Gittings Case V-P.'s

RACINE, WIS., Nov. 6—Milton H. Pettit, formerly of Kenosha, Wis., was elected vice-president in charge of plants and production of the J. I. Case T. M. Co., this city, succeeding F. Lee Norton, who resigned as vice-president and general manager of the Case company several months ago. Ellis J. Gittings, whose appointment as manager of the sales department was announced a few days ago, has also been elected a vice-president, in charge of sales. Richard T. Robinson, for many years secretary of the company, also resigned recently, as noted, and is succeeded by W. F. Sawyer, formerly sales manager.

E. G. Norris McQuay-Norris Branch Mgr.

SEATTLE, WASH., Nov. 5—E. G. Norris has been appointed Northwest district branch manager of the McQuay-Norris Company, of St. Louis. He is a brother of W. K. Norris, president of the corporation which manufactures Leak-Proof piston rings. He will have supervision of Washington, Oregon, Idaho, Montana and British Columbia business, with headquarters in Seattle.

Ferro Brings Out a Twelve

On Same Lines as Ferro Eight—Overhead Valves with Detachable Cylinder Heads

CLEVELAND, OHIO, Nov. 10—It has for a long time been an open secret that the Ferro Machine & Foundry Co., this city, has been developing a twelve along the lines of the Ferro eight designed by Alanson P. Brush. It is understood that more than one experimental motor has been built and it is now announced that the size chosen for the standard product will be 2⅞ by 4½ in., giving 350.5 cu. in. displacement.

The features of the Ferro eight were commented upon and illustrated in the last issue of THE AUTOMOBILE, so there is no need to recapitulate them here, save to say that the new engine will have a twenty-four-cam camshaft and that the rocker mechanism will permit of easy adjustment of the tappets. The main features of the motor are as follows:

Weight—without starter or generator	730 lb.
Bore	2⅞
Stroke	4½
Formula hp.	39.7
Total piston displacement	350.5 cu. in.
Mean valve diameter	1¼
Valve lift	0.253
Firing order	R. 1-5-3-6-2-4 L. 1-5-3-6-2-4

Three crankshaft bearings.

Three camshaft bearings

	Dia.	Length	Dia.	Length
Front	1⅞	3 3/16	1⅛	1 15/16
Center	2	2¼	1¾	2
Rear	2⅛	2⅞	1	1 13/16

	Dia.	Length
Connecting-rod bearings side by side	2⅛	1 3/16

Starter gear ratio	10:1
Timing gear type	Morse chain
Valve type	Overhead inclosed
Lubrication	Pressure feed
Cooling	Pump

Myers Again Stutz Sales Manager

INDIANAPOLIS, IND., Nov. 6—W. D. Myers, who was sales manager of the Stutz Motor Car Co., this city, and resigned a little over a year ago, has returned to his old position with the Stutz company, that of sales manager. At the same time, announcement is made of the resignation of H. W. Anderson, sales manager of the Stutz company, effective on Nov. 1.

Mr. Myers resigned from the Stutz company to organize the Myers-Ebersole Motors Co., Kansas City, Mo., which controlled the agency for the Cole and Regal cars. This business will be continued under the management of J. H. Ebersole, though Mr. Myers will retain his interest.

Mr. Anderson, who has been identified with the automobile business for the past ten years, has not yet announced his plans for the future, but will make his headquarters at the Hotel Astor, New York City, for the present.

New Company Will Finance Time Payments On Overland Cars

Guaranty Securities Co. Formed in Toledo with Plan for Carrying Installment Paper—Three Kinds of Discount Facilities—Special Plan for Farmers

TOLEDO, OHIO, Nov. 8—Dealers selling Overland and Willys-Knight cars are now offered facilities for financing time payments on cars by a new securities company in this city, known as the Guaranty Securities Co. A guaranty plan has been worked out whereby the burden of carrying instalment paper is removed from the dealers' and distributors' shoulders and carried by the Guaranty Securities Co. Three distinct kinds of discount facilities are afforded the dealers by the new plan, namely, the discount of instalment notes on retail sales, the discount of farmers' notes on retail sales, and the discount of paper growing out of sales at wholesale by distributors to dealers, with particular reference to the winter stocking season.

In the working out of the plan, the Willys-Overland Co. has advised and suggested a course which would benefit Overland dealers, but the Willys-Overland Co. is not in any way connected with the Guaranty Securities Co.

Plan Good for Any Model

It is a method which will undoubtedly effect a great change in the selling of Overlands, for by its provisions, any dealer is in position to sell a man a machine of any model manufactured by Overland on a time basis. The buyer must, of course, be a responsible party whose notes will be good security.

Briefly, the guaranty plan consists in the securing of a down payment by the car buyer of a certain prescribed amount as given in the accompanying table, and the balance in eight monthly instalments, a note being given for each instalment. The notes secured by the dealer are then sent through the distributor to the Guaranty Securities Co., which concern discounts them, remitting all of the face value of the notes except an amount running from $100 to $200, depending upon the value of the car. This amount the dealer receives a deferred certificate for, and it is payable when and if the customer's notes are paid. But if a dealer does not want to wait for this portion of the profit, he can immediately cash the certificate at a discount of 5 per cent. This does not apply to deferred certificates on farmers' notes, which certificates are not discountable.

Going into the details of the plan, the car buyer is required to pay a small amount in excess of the list price of the car, this being for insurance and interest on the unpaid balance. The insurance covers fire, theft and transportation loss and is written under a blanket policy in the Automobile Insurance Co., Hartford, Conn., which is affiliated with the Aetna Life Insurance Co. Any scheme of reports or checking in order to make sure that insurance had been properly written on each car would be so cumbersome and costly as to be prohibitive. Therefore it was decided that the insurance should be covered by a blanket policy, it is pointed out, and that the charge for this insurance should be made in a lump sum and treated as a part of the time price of the car.

Books Sell for $1 Each

Forms have been provided on which to make the sales of cars under the guaranty plan in each of the different States so as to conform to the various laws. These forms are furnished to the dealers at $1 per book.

In making a sale under the plan, the first thing the dealer does is to make the necessary inquiries of the buyer so as to fill out the purchaser's statement intelligibly. This statement is one of the forms supplied. The mortgage and notes are then filled out, and the insurance requisition. From the moment this insurance blank is filled out and mailed by the dealer, the car is covered against fire and theft. A certificate of participation, showing the interest of the purchaser in the insurance, is issued in duplicate when the papers reach Toledo, one copy going to the customer and one accompanying the notes as collateral.

Having made the deal, the dealer indorses the notes, signs the assignment on the back of the mortgage, sending the papers on to the distributor. The latter also indorses the notes, signs and dates the mortgage or assignment and sends all the papers on to the Guaranty Securities Co. The latter then sends the money and deferred certificate to the distributor, from whom the Guaranty company actually buys the notes, but if the distributor receives them from a dealer, he at once indorses both check and certificate and sends them on to the dealer.

Dealer Must Handle Repossessions

The purpose of holding back the $100, $150 or $200 in the form of a deferred certificate is two-fold: First, the dealer's interest must be tied to the transaction until all the notes are paid, as the Guaranty Securities Co. is not in, and cannot enter, the automobile business, and in the event of a repossession of one car out of a hundred, it is necessary that the dealer handle the repossession. Therefore, it is thought only fair that he should wait for a part of his profit until his customer has paid out. The second reason is that the deferred certificate is necessary to provide the required borrowing margin for the Guaranty Securities Co. to finance the proposed purchases of this paper, which are likely to run into several million dollars. This money must come from banking centers, and in order to borrow it at the proper rate and in such unlimited quantities as to comply with the Guaranty Securities Co. arrangement with the Willys-Overland Co., it is stated that a margin of 25 per cent in the notes is necessary, so that they may deposit $1.25 worth of notes against every dollar borrowed. This margin is obtained by the deferred certificate. As already stated, these certificates are, however, cashable through the distributors at 5 per cent discount, and the distributors can in turn use them in lieu of cash in paying for cars or other merchandise bought of Overland, at a discount of 50 cents per month for the unexpired term of the customer's notes. If the certificates are for $150, the charge is 75 cents per month; $200, $1 per month.

Monthly Installment Sales Table

		Model 83		Model 84		Model 86,
		Touring	Roadster	Touring	Roadster	Touring
1	List—f.o.b. Toledo	$750.00	$725.00	$1,095.00	$1,060.00	$1,145.00
2	Interest and insurance charge	25.00	25.00	35.00	35.00	35.00
3	Time price	775.00	750.00	1,130.00	1,095.00	1,180.00
4	Cash down	275.00	250.00	530.00	495.00	580.00
5	Note one month	50.00	50.00	75.00	75.00	75.00
6	Note two months	60.00	60.00	75.00	75.00	75.00
7	Note three months	60.00	60.00	75.00	75.00	75.00
8	Note four months	60.00	60.00	75.00	75.00	75.00
9	Note five months	65.00	65.00	75.00	75.00	75.00
10	Note six months	65.00	65.00	75.00	75.00	75.00
11	Note seven months	75.00	75.00	75.00	75.00	75.00
12	Note eight months	75.00	75.00	75.00	75.00	75.00
13	Total notes	500.00	500.00	600.00	600.00	600.00
14	Deduct interest and insurance	25.00	25.00	35.00	35.00	35.00
15	Deduct discount	7.50	7.50	9.00	9.00	9.00
16	Proceeds	467.50	467.50	556.00	556.00	556.00
17	Cash	367.50	367.50	406.00	406.00	406.00
18	Deferred certificate	100.00	100.00	150.00	150.00	150.00
19	Cash from customer	275.00	250.00	530.00	495.00	580.00
20	Cash from G. S. Co	367.50	367.50	406.00	406.00	406.00
21	Total cash	642.50	617.50	936.00	901.00	986.00
22	Five car dealers cost	630.00	609.00	920.00	895.00	962.00

For farmers' accommodation, the plan is a little different. The farmer is accustomed to pay for his goods at harvest time, and in order to meet his requirements the Guaranty Securities Co. has modified its arrangement on installment paper so that a note or notes may be given for the deferred payment due at any time up to eight months. Further, the farmers' notes will be purchased direct from dealers as well as distributors, and will not be handled through the latter at all. The deferred certificate issued on farmers' notes cannot be discounted, but must be held by the dealer making the sale until the notes are paid.

The procedure in making the sale to a farmer under this plan is substantially the same as in the deferred payment method, except that the mortgage, contract of conditional sale, or lease will not be assigned to the distributor, but the bottom assignment printed on the back of the form, running directly to the Guaranty company, will be used by the dealer instead.

Third Plan—Sight Drafts

Due to the fact that dealers in very many cases are unable during the winter season to borrow suitable amounts with which to take their allotments in cars from the distributors, and because dealers often ask for assistance so that instead of having a large number of cars in warehouses and distributing points they would be more generally distributed through the country in the hands of dealers, where they can be seen by possible buyers, the third kind of discount facilities was fostered by the Guaranty company. The plan is for the distributor to draw his draft at 1 to 4 months sight on the dealer, with bill of lading attached. These drafts will bear interest from the date of their acceptance, and each draft will usually cover a carload of cars. Drafts may be paid in whole or in part at any time up to their maturity, and interest will cease on each car covered by the draft as paid for.

There is no cost to distributor involved in this plan, as the Guaranty Securities Co. will buy the acceptances from the distributor for their face value less only the cost of accommodation. In other words, the distributor will get his full dealer price for the cars out of the acceptance. The proceeds of the draft will be sent to the distributor in cash except that a deferred certificate for $150 per car will be issued, payable when and if, the acceptance is paid by the dealer.

—

Allen Plant Is Busy

BUCYRUS, OHIO, Nov. 6—The Allen Motor Co., which recently finished an addition to its motor plant at Bucyrus, reports its shops working day and night for the past sixty days and is not yet caught up on its orders for the touring car.

Buffalo Engineers Talk Motors

—

Many Automobile and Motor Engineers Among 350 at Eng. Society Meeting

BUFFALO, N. Y., Nov. 4—At a meeting of the Engineering Society of Buffalo held at the Statler hotel last night, the subject of multi-cylinder gasoline engines was discussed. There were 350 members of the society in attendance, many of whom are prominent in the automobile industry.

The subject was presented by O. E. Hunt of Detroit, engineer of the Packard Motor Car Co., and the discussion was carried on by David Fergusson, engineer of the passenger car department of the Pierce-Arrow Company; O. E. Spillman of the Herschell-Spillman Co., Tonawanda; Ernest Harris, assistant to Mr. Fergusson, and Otto Burkhardt, also of the Pierce plant.

Mr. Hunt's presentation included the letter which J. G. Vincent wrote the Packard company urging the concern, of which he is vice-president, to build a twin six motor. Mr. Hunt dwelt on the engineering considerations in designing a twelve-cylinder car in particular and a multi-cylinder type in general. Mr. Fergusson defended the six and sought to prove by scientifically worked-out diagrams that the characteristics of the six-cylinder motor with the cylinders arranged in a single row are as good as those of the twelve or twin six arrangement.

—

Detroit Chassis Co. Formed

DETROIT, MICH., Nov. 5—The Detroit Chassis Co. has been organized temporarily capitalized at $10,000 and has leased the plant formerly occupied by the Vitralite Co., west Grand Boulevard and Hubbard Avenue, where manufacturing of a standard chassis has been started.

It is the object of the new company to cater especially to carriage and buggy makers and offer them a chassis at a reasonable price.

Before the new concern decided to organize those interested in it investigated the possibilities of the undertaking and came to the conclusion that the idea was a good one. In fact the company started with several large orders, one of which is for 600 chassis for Smith & Sons, London, Eng.

Instead of putting out a chassis with a specified line of parts or components such as carbureter, ignition system, starting and lighting system, this part of the equipment will be entirely optional with the party or concern placing an order, and the price will naturally be made according to the equipment required. The chassis itself will be only made in one size, 110 in. wheelbase. The motor will be a four-cylinder block, 3¼ by 5. The wheels will be of the artillery type, with 32 by 3½ tires.

—

To Discuss Philadelphia S. A. E. Section

NEW YORK CITY, Nov. 9—A meeting of the S. A. E. members located in Philadelphia will be held in that city to-morrow for the purpose of discussing the advisability of forming a local organization to carry on activities in that vicinity. A dinner will start the program of the evening after which there will be addresses by members of the council of the society and by members of the governing committee of the Metropolitan section who have been invited to attend.

—

Schipper Treasurer Metropolitan S. A. E.

NEW YORK CITY, Nov. 9—At a meeting of the Governing Committee of the Metropolitan Section of the Society of Automobile Engineers, J. Edward Schipper, technical editor of THE AUTOMOBILE, present secretary of the section, was appointed treasurer to succeed Prof. W. C. Marshall, who recently resigned. The governing committee of the section now consists of R. McA. Bloyd, chairman; J. Edward Schipper, secretary-treasurer; N. B. Pope and Joseph A. Anglada.

—

Gray Is Haynes Advertising Manager

KOKOMO, IND., Nov. 8—R. T. Gray has been appointed advertising manager of the Haynes Automobile Co., this city, and has already taken up his duties.

Mr. Gray is a graduate of the Engineering Department of Purdue University, and is well versed in the technicalities of the automobile, as well as having had considerable experience in general advertising.

—

Logan with McGraw Tire

EAST PALESTINE, OHIO, Nov. 4—W. V. Logan, recently manager of the manufacturers' department of the Goodyear Tire & Rubber Co., is now associated with the McGraw Tire & Rubber Co. in the capacity of assistant general sales manager. His efforts for the immediate future will be confined to the opening of new accounts with passenger and commercial car manufacturers.

—

Germans Make Alcohol from Potatoes

LONDON, ENG., Nov. 5—A report from Germany states that that country is making great use of its potatoes, of which there is a great surplus. One of the results is wood alcohol, with which automobiles are now largely driven.

—

Three Bodies for National Twelve

INDIANAPOLIS, IND., Nov. 6—The National Motor Vehicle Co., this city, will equip its new Highway Twelve w

three types of bodies for 1916, including a three-passenger roadster, a four-passenger coupé and a five-passenger sedan.

All three of these body types follow out the same general trend of National body construction that has been noted in previous models. The Highway coupé sells for $2,650; the five-passenger sedan has a center door on the right side and a forward door on the left, and sells for $3,200; the three-passenger roadster sells for $1,990.

—

Goodyear Gross Business Totals $36,000,000

AKRON, OHIO., Oct. 5—Gross business of the Goodyear Tire & Rubber Co. for the fiscal year to Oct. 31 last reached a new record of over $36,000,000, an increase of $5,000,000, or 16 per cent over 1914, and $11,000,000 over 1912. The company turned out more than 2,000,000 tires during the year, but in the last three months has been making 12,000 to 13,000 a day, at an annual rate close to 4,000,000. In the year 1913-1914, 1,479,883 tires were sold.

—

Chalmers Stock to Pay $12 a Share

NEW YORK CITY, Nov. 4—The Chalmers Motor Co., Detroit, which has been paying at the rate of $10 a share annually on its common stock for the past four years, will start the year 1916 with an increased rate. The new basis, it is understood, will be $12 a share annually, or at the rate of $3 quarterly. The increase will start in January and will be due to enlarged production and earnings, profits so far indicating a surplus for the current fiscal year equal to $30 a share on the common. The stock is $100 par value and is selling at 160.

In August, 1910, the company declared a stock dividend of $900 a share. In October, 1912, another stock dividend of 33 1-3 per cent was declared, followed in June, 1913, with another stock dividend of 25 per cent.

—

Olds Sales Gain 133%

LANSING, MICH., Nov. 5—Sales of the Olds Motor Works during August, September and October, are reported to have been 133 per cent larger than during the same period last year. The increase would have been greater had it not been impossible to produce cars in sufficient number. Production is now being increased as much as possible and the manufacturing floor space has been increased for that purpose.

—

House with Vacuum Oil

DETROIT, MICH., Nov. 5—C. M. House, who was engineer of the Briggs-Detroiter Co. is now with the engineering staff of the Vacuum Oil Co. at their headquarters in Detroit.

Earn 19% on New Peerless Stock

—

Based on Actual Shipments of Combined Subsidiaries for Calendar Year

NEW YORK CITY, Nov. 9—The books and accounts of the Peerless Motor Car Co., Cleveland, Ohio, and the General Vehicle Co., Long Island City, which were merged to form the Peerless Truck & Motor Corp. last week, indicate, according to a preliminary examination by Touche, Niven & Co., chartered accountants, that the earnings from actual shipments of the combined companies for the current calendar year are at the rate of 19 per cent per year on the new $10,000,000 of capital stock of the new corporation. This is after deducting interest charges on the $5,000,000 of new notes and after setting aside liberal amounts covering depreciation, etc.

Aside from the notes mentioned, the corporation will have no bonded indebtedness, except a mortgage of $300,000 on the real estate and building which it owns at Fifty-seventh Street and Broadway, this city, which is used partly as a sales depot, the equity in which exceeds the amount of the mortgage, and returns a good income.

Assets are said to have been reduced to a conservative basis by writing off all bad debts and substantial amounts covering depreciation of buildings and equipment, though both the Cleveland and Long Island City plants are of recent construction, in good condition and in a high state of manufacturing efficiency. The consolidated net current working assets of the new corporation, exclusive of plants and equipment, will amount to $3,378,000 in excess of all liabilities, $2,370,000 of this being cash in banks.

The total capitalization of the new corporation, which is organized under the laws of Virginia, is $20,000,000, all common stock, of which $10,000,000 is to be issued now while the balance is to be reserved for the conversion of the new $5,000,000 ten-year 6 per cent notes convertible after one year into stock of the corporation at par, which is $50 per share.

Probable Board of Directors

While the composition of the board of directors of the new corporation has not yet been definitely determined, it is probable that it will include the following:

C. V. Rich, vice-president of the National City Bank and president of the National City Co.; E. R. Tinker, Jr., vice-president Chase National Bank; P. J. McIntosh, 26 Broadway, president of General Gas Appliance Co., director of Montreal Public Service Corporation, Halifax Electric Tramway Co., Imperial Trust Co., Montreal, United States Industrial Alcohol Co., etc.; B. G. Tremaine, F. S. Terry, identified with General Electric Lamp Works at Cleveland; P. D. Wagoner, president of General Vehicle Co., Long Island City; L. H. Kittredge, president of the Peerless Motor Car Co., Cleveland; Harrison Williams, identified with Cleveland Electric Illuminating Co. as chairman of the board, also with Republic Railway & Light Co., Federal Utilities, Inc., etc.

The management of the subsidiary companies comprise the following directors for the Peerless Motor Car Co.: L. H. Kittredge, president; T. W. Frech, vice-president; L. H. Treadway, president of Peck, Stow & Wilcox Co.; A. B. McNairy, director of Cleveland Trust Co.; C. E. Sullivan, vice-president Central National Bank, Cleveland; H. A. Tremaine, J. B. Crouse, associated with the National Lamp Works of the General Electric Co.; and G. B. Siddall, president of the Lorain & Southern Railway.

Directors of the General Vehicle Co. are: P. D. Wagoner, president; A. W. Burchard, vice-president of the General Electric Co.; M. F. Westover, secretary of the General Electric Co., and E. A. Carolan, A. K. Baylor, W. B. Potter and F. C. Pratt, all identified with the General Electric Co.

—

Stewart-Warner Earnings Estimated at 16 Per Cent on Common

CHICAGO, ILL., Nov. 4—Stewart-Warner Speedometer earnings for nine months ending Sept. 30, exceed entire earnings of 1914 and this year's earnings are estimated at 16 per cent on common stock. The company retired out of earnings $246,000 preferred stock.

The profits of the corporation for the quarter ended Sept. 30, amount to about $447,000, a record for any three-month period. For the nine-month period the profits were $1,221,350, against $848,127 for this period last year.

Plans are being prepared for a factory, six stories, at Wolfram Street and Lincoln Avenue.

—

Timken Roller Bearing Business 120 Per Cent Over 1914

DETROIT, MICH., Nov. 5—The business of the Timken Roller Bearing Co. shows an increase of 120 per cent for October over the same month's business in October, 1914, and an increase of 25 per cent over the business of September, 1915, according to Herman Ely, secretary of the company. This increase is not due to war orders but to the natural increase in car manufacturers' business.

—

Musgrave with Pathfinder

INDIANAPOLIS, IND., Nov. 5—H. G. Musgrave has been appointed assistant director of sales of the Pathfinder Co.

Stevens-Duryea May Resume

Negotiations Under Way for Sale of Springfield Property —New Capital Interested

SPRINGFIELD, MASS., Nov. 6—There are persistent rumors that the Stevens-Duryea cars will be manufactured again. Negotiations are in progress for the sale of the Olmstead and Tuttle factory situated off Springfield Street that has a taxed value of $69,000. James L. Doherty, trustee of the estate, admitted that negotiations are under way for the sale of the property, but he refused to say who the prospective buyer was. Officials of the New England Westinghouse Co. which bought the Stevens-Duryea plant stated that they were not looking for any other factories at Springfield. So the talk about the Stevens-Duryea reorganization became current again. The company still has its plant for the making of parts to supply owners, but it is not large enough for manufacturing purposes. But the Olmstead and Tuttle factory would give it the needed facilities. According to the information gleaned a new charter will be applied for and work started on some cars again with new capital furnished by others not identified with the old company.

—

Gunn U. S. Tire President

NEW YORK CITY, Nov. 4—J. N. Gunn has been chosen as the new president of the United States Tire Co. in full charge of manufacturing and selling. He has also been appointed assistant to the president of the United States Rubber Co., of which the tire company is a subsidiary. E. S. Williams resigns the presidency of the tire company in order to devote most of his attention to the mechanical rubber business of the United States Rubber Co.

Mr. Gunn has been assisting the tire and parent company since last June in important efficiency work. During this work Colonel S. P. Colt, president of the parent company, arranged to have Mr. Gunn become assistant to the president, and at the same time, because of the desire of Mr. Williams to be relieved to a great extent from the work of directing the tire company, the recommendation by Williams that Gunn be made president of the tire company, was also put into effect.

Mr. Gunn has been a prominent figure in the automobile field, having been for 1½ years general manager of the Studebaker Corp. He has been the head of Gunn, Richards & Co., New York City, business and efficiency engineers. For the purpose of systematizing and straightening out the plan of administration of the Studebaker Corp., following the merging of the Everitt-Metzger-Flanders Co., Detroit, and the Studebaker Bros. Mfg. Co., South Bend, Ind., in 1911, he took the general managership from December, 1911, until July, 1913, when his work was completed.

S. P. Colt, president of the United States Rubber Co., states that earnings this year will not be as large as in 1914. He states that it is costing that company considerably more to make tires now than it did in the early part of the year. The cost of fabric used by this company in the make-up of tires is probably 20 per cent higher than at the start of the year. Crude rubber is about 6 cents higher than then. Some other articles used in the manufacture of tires are no higher, but the materials used average in the neighborhood of 10 per cent more than a year ago.

The company is now turning out over 8000 tires a day. It is its intention to bring the tire capacity up to between 13,000 and 14,000 tires daily in the near future.

—

Approve Plan for Paying Maxwell Back Dividends

NEW YORK CITY, Nov. 10—At a special meeting held here to-day the holders of the stock trust certificates of the Maxwell Motor Co. ratified the plan recently submitted by the directors for the retirement of the accumulated 14¼ per cent back dividends on the first preferred stock by the issue of non-interest-paying warrants convertible into first preferred stock at par. The issue of $1,050,000 additional first preferred stock was also authorized at the meeting.

—

Studebaker Heads $1,000,000 Tire Co.

SOUTH BEND, IND., Nov. 5—Peter E. Studebaker, son of the late Henry Studebaker, one of the founders of the Studebaker Corp., has accepted the presidency of the International India Rubber Tire Co., a $1,000,000 corporation recently organized in South Bend. The concern will make automobile tires and sell direct to the dealers.

The officers of the company are: E. H. Schwab, Bethlehem, Pa., vice-president; G. W. Odell, Findlay, Ohio, secretary; J. R. Nobile, treasurer. These men, with William S. Moore, city engineer of Grand Rapids, Mich., form the board of directors. The plant will be in South Bend.

E. R. Erskine, president of the Studebaker Corp., in response to an inquiry, stated that the proposition is yet in embryonic state and that neither the Studebaker Corp. nor any of its officials are interested financially or commercially in the proposition.

Studebaker Earns $10,000,000?

Per Share Surplus of $30 as Compared with $15 in 1914

NEW YORK CITY, Nov. 4—Earnings of the Studebaker Corp. for 1915 will fall slightly short of reaching the $10,000,000 mark, compared with a surplus for 1914 of $3,752,916 after allowing a charge-off of $402,698 for "extraordinary expenses." On the $27,931,600 common stock now outstanding these profits work out a per share surplus this year of somewhat over $30, compared with just under $15 last year.

Mostly Domestic Business

The larger part of this earning power of between $9,000,000 and $10,000,000 is from domestic business entirely.

Last week was a record one with shipments of 1510 cars, and October was the record month, with shipments of 6009 cars. All these machines were for domestic consumption. The company is doing an excellent export business to South and Central America, Australia and the Far East. Its domestic demand, especially in the East, has been very heavy. The sales in Boston, Philadelphia, and New York in the past year have doubled.

The directors of the company yesterday declared a quarterly dividend of 1½ per cent on the common stock, and an extra dividend of 1 per cent. According to a statement issued by President A. R. Erskine, this places the junior shares on a regular 10 per cent annual basis. His statement reads:

Orders Running High

"It is the belief of the management that the 1 per cent extra dividend will be declared regularly hereafter, as the current business of the company, exclusive of any so-called war orders of which the company has been a recipient, is running at a rate which will fully justify a 10 per cent return to stockholders, and will leave ample surplus earnings for the extension of the business without any necessity for borrowing."

"The corporation is now entirely free from floating debt excepting $2,308,500 of serial notes, respecting which arrangements have been made to call which is the earliest possible date on which they can be paid in accordance with the indenture under which they were issued."

The Studebaker common dividend since May 4, 1915, has been on a 5 per cent basis, 1¼ per cent having been declared quarterly. Studebaker shareholders were recently offered the right to subscribe to 26,380 shares of treasury stock at $110 a share.

Monarch To Concentrate on Eight

Adopts Distinctive Silver-Aluminum Finish for Wheels —Price Is Unchanged

DETROIT, MICH., Nov. 8—The Monarch Motor Car Co., this city, will produce only one stock model for 1916, an eight-cylinder, seven-passenger touring car, which it has christened, "the car with the silver wheels." The price remains at $1,500. Mechanically the car is the same model as previously brought out, but a number of refinements have been made in the body and finish to bring the car up to the latest design.

3 by 5 High-Speed Motor

The motor is a 3 by 5 Herschell-Spillman with the cylinder blocks set at a 90-deg. angle. The cylinders are slightly staggered, allowing the connecting-rods to be placed side by side on separate bearings, thus avoiding the yoke-end construction. The motor is essentially of the light weight, high-speed type, and will develop upwards of 74 hp. at 2400 r.p.m., according to its manufacturer. Two mufflers are used.

The gearset on the new model is made by the Detroit Gear and Machine Co., and is in unit with the motor. Drive is by tubular shaft through a double universal of standard design. Axles are of Columbia make, the rear being floating with spiral bevel gears. Gemmer steering gear is used and the drive is from the left with center control, the gearshift lever operating on the power transmission direct.

The rear springs are three-quarter elliptic and take the driving stresses. The brake rod assembly has been altered somewhat to secure a thoroughly accessible and powerful construction, and both sets are on the rear wheels. The frame has been altered so as to have a slight kick-up in the rear.

Zenith Duplex Carbureter

The carbureter is a Zenith of the duplex, eight-cylinder model, and the ignition is by the Atwater Kent automatic advance system. Starting and lighting is Ward Leonard, especially adapted to the Monarch car with flywheel application through a Bendix driving pinion. The two-unit system is used, with the motor for starting separated from the generator for lighting. Fuel feed is by Stewart vacuum system. The gasoline tank is in the rear and has been increased in capacity.

Upholstery is flush type, and of genuine, long-grain leather, being cut away from the back of the front seats, giving the effect approaching that of the double cowl body. Fenders are crowned and rounded to the curve of the wheels, which are silver-aluminum finished, giving the car its name.

The wheelbase of the Monarch is 125 in. Tires are 33 by 4½, safety tread in the rear. Equipment is unusually complete.

—

6-Tonner Completes Worm Line of Gramms

LIMA, OHIO, Nov. 6—Completing the line of worm-driven trucks produced by the Gramm-Bernstein Co., Lima, Ohio, a new model rated at 5 to 6 tons capacity has recently been added to the 1916 offering of B. A. Gramm trucks. The other trucks are 1, 1½, 2½ and 3½ tons size respectively, and all models are similar in general lay-out.

The new heavy-weight replaces the former 6-ton chain-driven B. A. Gramm, and like all of the more recent B. A. Gramm productions has its motor under a conventional hood instead of between the seats as in the first 2- and 3-ton models. Another departure to be found in this model is in the motor, which, instead of having six cylinders as previously, has but four, the new four, with cylinders 4½ by 6¾ in., has 375 cu. in. displacement, the respective horsepower ratings by the standard formula being 40.8 for the six and 32.4 for the four.

The present B. A. Gramm line consists of the following models, tabulated according to principal specifications:

Capacity, Tons	1	1½	2½	3½	5-6
Price ...	$1,500	$1.800	$2,600	$3,400	$4,300
Wheelbase	118	130	156	158	168
Tires, front	34x3	34x3½	36x4	36x5	36x6
Rear...	34x4	36x5	36x4d	40x5d	40x6d
Drive....	worm	worm	worm	worm	worm

Any of these models will be equipped with an electric lighting and starting system for $200 extra, or with the lighting system only for $100 extra.

Choice of Stromberg or Zenith carbureters is offered on chassis either for domestic or export purchase, fed by gravity from a tank beneath the seat. A Bosch magneto is used for ignition.

—

De Tamble Equipment Sold for Taxes

ANDERSON, IND., Nov. 4— The equipment of the De Tamble Motors plant was recently sold for delinquent taxes to Elmer Eckhouse of Indianapolis. The property consists of all machinery, engines and boilers that go to make up the plant. The amount of delinquent tax due the county by the company was $1,150.

Negotiations, it is said, are being made for the resumption of operations at the De Tamble plant. An out-of-town concern has taken up the matter of re-opening the plant, which has been practically idle for two or three years.

Cummins-Monitor Adds a Six

3 by 5 In. L-Head Motor—Car Sells for $895—To Continue Four

COLUMBUS, OHIO, Nov. 6—For 1916 the Cummins-Monitor Co., this city, will add a six-cylinder to its line, to sell at $895, and continue the four-cylinder touring car and roadster models previously made, selling at $795. The motor used in the six-cylinder model is a 3 by 5-in. L-head, designed along the lines of accessibility and light weight.

The chassis is rigidly braced and reinforced to withstand the hardest usage, yet is free from complications. A simple system of brake equalization is used, which has proved very efficient in the test of the new six. The front springs are semi-elliptic and the rear, three-quarter elliptic, underslung, with a swinging saddle, designed to prevent the usual solid impact when passing over very rough roads.

Tires are 33 by 4 with non-skids in the rear. Wheels have large drums with internal expanding and external contracting brakes, the latter being leather-covered to protect the linings from dirt and grit. The rear axle ratio is 4 to 1.

The body, which is mounted on a 115-in. wheelbase, has been designed to give ample room, both in the front and rear compartments. Upholstering is in genuine leather, and the cushions are built with extra deep springs and with a gradual slope toward the back. The body is finished in Brewster green with dark blue as an option, with the rest of the car in back. Vacuum fuel feed is employed, the gasoline tank being in the rear.

Slight Changes in Fours

Very slight changes are to be noted in the four-cylinder models. The 4-30, which has a 108-in. wheelbase, is a streamline design. Fuel is carried in the rear of the roadster and under the cowl of the touring car. The motor used in the four is a Golden, Belknap and Swartz, 3¼ by 4¼. Cylinders are block-cast, with removable head. Lubrication is by force feed to the main bearings, but the splash system is used for the other parts.

Cooling is by thermo-syphon, and the clutch is a multiple disk, the gearset being three-speed selective.

The rear axle is a Russell floating type, with 1¼-in. shafts. Hyatt roller bearings are used in the axle and the driving shaft. Brakes are inclosed to prevent mud and dust from reaching the linings. The steering gear is of the irreversible type and has a 17-in. wheel.

Splitdorf ignition is used with a 12-volt Disco electric generator and motor for cranking and lighting. Tuthill semi-elliptic springs are found in the front of the four and three-quarter elliptic in the rear.

Speedometer, ignition switch, ammeter and lighting switch are carried in a unit case on the instrument board and are illuminated at night by a dash lamp. The windshield is rain-vision, ventilating. Tires are 32 by 3½, non-skid in the rear, with demountable rims and one extra rim goes with each car.

—

Jeffery Sedan for $1,165

KENOSHA, WIS., Nov. 6—The Thomas B. Jeffery Co., this city, has brought out a sedan for its four-cylinder chassis to sell at $1,165. The sedan top is easily removed, converting the car into an open machine at the first approach of warm weather.

The entire car is built in the Jeffery factory, and looks like a permanent inclosed car.

The roof of the car is of laminated wood construction covered with a fine quality of top material. The rear section of the body of the top is metal, and the supports and sills are of a very substantial character. Yet with all this strength and appearance of permanence, the weight of the top is but approximately 200 lb. Taking into consideration the removal of the summer top, this makes a total added weight of a little over 100 lb.

The glass in the windows is of 3/16-in. crystal plate, ground and polished. In the broad forward windows and in the doors, the glass is arranged to drop half way. The rear window is extra large, providing more than ample light and vision. This window and the two rear side windows are provided with silk portiere curtains.

Because of the substantial construction of the top and careful padding between the top and main body of the car, there is said to be no rattle, even over the roughest roads. This careful padding also protects the top of the touring body—doing away with the need of refinishing when the top is taken off in the summer.

—

U. S. Truck Prices Lower

NEW YORK CITY, Nov. 6—The United States Motor Truck Co., Cincinnati, Ohio, has reduced its prices on its models E, D, H, J and K, effective in 1916. The old and new prices are as follows:

Model	Old Price	New Price
E	$2,550	$1,900
D	3,200	2,400
H	2,700	2,200
J	3,400	2,800
K	4,200	3,600

Stegeman Trucks Six and Two Fours

—

4-Ton Six Has 3¾ by 5¼ Motor of 50 H. P.—All Motors Continentals

MILWAUKEE, WIS., Nov. 6—The new line of worm-driven trucks announced by the Stegeman Motor Car Co., Milwaukee, Wis., employs the same style of motors as was used formerly in the chain-drive vehicles brought out by that concern—Continentals. In the 1½-ton and 2½-ton trucks, a 4⅛ by 5¼-in. four-cylinder motor, developing 35 hp. is used, while the 4½-ton machine is equipped with a 3¾ by 5¼ six-cylinder, 50-hp. motor. The makers declare that the six-cylinder motor will do away, largely, with the damaging internal vibration on the large machine.

Three-point suspension is employed and the motors all are equipped with sealed governors limiting the speed to 1100 r.p.m. The car speed of the 1½-ton is 18 m.p.h., the 2½-ton, 15 m.p.h. and the 3½-ton, 12 m.p.h. Lubrication is by a combination of the splash system and double plunger pump. Cooling is by centrifugal pump, gear driven, in connection with a large radiator. A Stromberg carbureter with a hot-air connection is used.

The frame is pressed steel, channel section. In the 3½-ton Stegeman, the frame is reinforced by nickel-steel truss rods. The standard wheelbase of the 1½-ton is 150 in.; of the 2½-ton, 144 in., but this model may be equipped with a special long wheelbase, which measures 162 in. The wheelbase of the 3½-ton is 156 in.

The standard tire equipment on the 1½-ton machine is 34 by 3½ solid front tires and 36 by 5 solid rear. On the 2½-ton, 34 by 4 solid in front and 36 by 4 dual solid in rear. The 3½-ton truck is equipped with 36 by 4 solid tires in front and 40 by 5 dual solid in rear. The standard tread of the 1½-ton is 56½ in.; the 2½-ton 58 in., and the 3½-ton, 65 in. However, a special country road 2½-ton is offered with a tread of 56½ in.

The chassis weights of the 1½, 2½ and 3½-ton models are 4200, 5000, and 6000 lb., respectively, and the prices in the same order, $1,900, $2,500 and $3,000. Any style of body will be supplied, to order.

—

Koehler 1-Ton Truck at $895

NEWARK, N. J., Nov. 6—Specializing in one type of chassis for a four-cylinder, shaft-driven, 1-ton capacity truck, the H. J. Koehler S. G. Co., Newark, N. J., plans a minimum output of 2000 machines for the 1916 season. This concern's product, known as the model K, sells for $895, has a wheelbase of 129 in., is equipped with a complete, roomy, flare-board type of body, perfected for the purpose of meeting a general demand for a full-ton carrying capacity. Besides, the truck is designed for speed, assuring rapid transportation.

The power plant is of the unit type, combining the motor, clutch and gearset. Three-point suspension is used. The four-cylinder motor has a 3 1-2-in. bore and a 5-in. stroke, is of the valve-in-head type, and develops 30 hp. Cylinders are block-cast, the upper part of the crankcase being cast integral. A jacketed cylinder-head contains the entire valve arrangement for the four cylinders and is easily removed. An important feature of the motor is that the exhaust gases have a quick outlet to the manifold, separate from the cylinder head, thereby giving immediate expulsion of the exhaust heat from the cylinder head ports, allowing valves and adjacent parts to be cooler and taking a burden from the cooling system.

A cone type clutch is housed with the flywheel and the gearset. Three speeds forward and one reverse are offered. All gears are made from an alloy steel containing proper parts of nickel and the shafts are mounted between annular ball bearings.

A special feature of the spring suspension is the use of graded springs both in front and rear. These springs are built up of four different thicknesses of leaves.

The internal gear drive type of rear axle is employed, all working parts of which are mounted on heavy-duty roller bearings. Both front and rear wheels are 34 in. in diameter.

—

Moreland Distillate Truck Lowers Prices

LOS ANGELES, CAL., Nov. 5—The Moreland Motor Truck Co., maker of Moreland distillate trucks, this city, has announced a sweeping reduction in prices for the coming year, as follows:

Capacity	Old Price	New Price
1-ton	$1,850	$1,150
1½-ton	2,200	1,850
2½-ton	2,800	2,400
4-ton	3,650	3,200

Continental four-cylinder motors are used in the full line except for the 4-ton model, which employs a special motor of Moreland construction. The 1-ton Continental motor is of 3¼ by 5, the 1½-ton model is 4⅛ by 5¼, while the 2½-ton is 4½ by 5½. The Moreland motor on the 4-ton is 4¾ by 6¾ in.

All of the motors are fitted with the Moreland gasifier, a fuel economizer produced by the Moreland company. Proceeding on the theory that No. 1 engine distillate, a clear, colorless liquid with a gravity test of 48, and selling at an average retail price of 6 cents a gallon, was the cheapest fuel to be had on

the Pacific Coast, the company developed the gasifier to take care of the heavier fuel. The action of the gasifier is simple. It is made of cast iron to give it heat-holding qualities and the exhaust and intake manifolds are cored through the outer shell, which completely envelops them. Fresh air is drawn through holes drilled in the top of this outer shell, directly upon the exhaust and intake manifolds, and this air, now heated, is drawn down into the air intake of the carbureter, heating the intake manifold at the same time. The fresh, warm air readily vaporizes the distillate in the carbureter, with the result that the mixture is carried through the warm intake manifold, and enters the cylinders as warm, dry gas which is readily ignited.

The wheelbases of the four models are 126, 150, 168 and 186 inches, respectively, for the 1, 1½, 2½ and 4-ton models.

—

DETROIT BANKRUPTS PAY DIVIDENDS

DETROIT, MICH., Nov. 9—The Detroit Trust Co., trustee for the old Briggs-Detroiter Co. is sending out a first dividend of 10 per cent to creditors of proved claims. A large number of claims are still being investigated and will be taken care of after having been approved.

DETROIT, MICH., Nov. 9—A fourth dividend amounting to 3 per cent has been paid to creditors of the bankrupt American Voiturette Co. The preceding dividends consisted of two 10 per cent dividends and one of 4 per cent, making a total thus far of 27 per cent dividends paid, or approximately $90,000.

DETROIT, MICH., Nov. 9—The Union Trust Co. will shortly pay another dividend of 10 per cent to the creditors of the bankrupt Church-Field Motor Co., Sibley, Mich. Two dividends, one of 15 per cent and the other of 10 per cent, have been paid to the creditors previously.

The trust company has also paid a 10 per cent dividend to the creditors of the bankrupt Benham Mfg. Co.

DETROIT, MICH., Nov. 9—The creditors of the bankrupt Krit Motor Car Co. of which Frank W. Blair, of the Union Trust Co. is trustee, have been paid a first dividend of 4 per cent. The creditors of the Krit Sales Co., of which Henry Lansdale is trustee, have received thus far two dividends, one of 25 per cent and the other of 12½ per cent.

—

Imperial Wheel Doubles Plant

FLINT, MICH., Nov. 4—The plant of the Imperial Wheel Works is being practically doubled in size. The present daily output is said to average between 1000 and 1200 wheels and it is to be considerably increased.

No Tire Shortage in England

—

Manager of Goodyear Co. of Great Britain Says Business Is Tranquil

AKRON, OHIO, Nov. 6—"We have been getting big shipments of tires in England, but even these have not permitted us to fill all our orders," says P. D. Saylor, managing director of the Goodyear Tyre & Rubber Co. of Great Britain, who has just arrived from London and is spending a few days at the Akron headquarters in the interest of Goodyear's European trade.

"Business is tranquil in London, and, contrary to the general opinion, there is no shortage of tires. It is true that the government has taken and is receiving now great quantities of tires from the manufacturers, but they have equipped themselves to take care of the increased business, and are able to fill the government orders and at the same time supply the trade. The tire manufacturers are pleased to get the government business and seek it.

"The advent of so many women into the trades formerly occupied solely by men at first occasioned not a little apprehension on the part of the trade unions, but this was amicably dispelled by the granting of men's wages to the women. All of the rubber companies are making up the difference between their men's present pay as soldiers, and their former salaries, forwarding the money to the families left behind. Consequently there is little distress among the families of the men at the front.

"The 33 1/3 per cent duty placed on automobiles has apparently had very little effect on the flow of American cars to England, as there is a strong demand for the medium-priced cars, occasioned largely by the shortage of horses. Many thousands of horses have been requisitioned by the government. The 40 per cent income tax increase, however, has begun to be felt, as has also the 50 per cent tax on the profits of all business houses, over an average of the last two years' profits."

—

Downey Heads Michigan Crank Shaft Co.

LANSING, MICH., Nov. 5—Charles P. Downey has been elected president of the Michigan Crank Shaft Co., while Oliver Meyer, formerly manager of the National Engineering Co., Saginaw, Mich., has become manager.

—

Electromobile Co. Consolidated

ST. LOUIS, MO., Nov. 6—The Electromobile Co. of St. Louis, maker of an electric indoor truck, has consolidated with the Orenstein-Arthur-Koppel Co. of Koppel, Pa., according to an announcement made here to-day by S. J. Bernheimer, president of the local company. Hereafter the Koppel firm will manufacture the truck and the Electromobile company will market the product in the Southwest. The latter company will continue to make headquarters here.

The truck, which was first exhibited at the 1914 St. Louis show, is now in general use in industrial plants here and in neighboring cities. The operator stands by the control at the rear of the truck.

—

Indorse Battery Standards

CHICAGO, ILL., Nov. 9—*Special Telegram*—At the weekly luncheon of the Chicago section of the Electric Vehicle Association, held at the Hotel Metropole to-day, W. F. Bauer, chairman of the local standardization committee, told of the work of his organization. The local committee's recommendations as regards battery standards coincide exactly with those of the parent body in specifying side-to-side assembly in trays and giving as the reason that in the end-to-end method jars are frequently broken due to the edges of the plates hitting the side of the jar whenever the vehicle is subjected to impact.

Wide latitude in assembly methods is left to the manufacturer by the committee as any number of cells to a tray between the limits of two and seven may be used.

The sub-committee on rubber jar sizes reported that it found twenty-eight different sizes prevailing, varying in dimensions from 1/16 to ⅛ in. This, Mr. Bauer declared, has forced manufacturers to keep large amounts of dead stock on hand to meet emergencies and is one of the factors responsible in keeping up the prices of lead batteries.

Regarding charging apparatus, it was suggested that a chart should be arranged to enlighten the garage man as to what he should do to eliminate losses through improper methods. Secretary McCall announced that the Commonwealth Edison Co. will give everyone who has charging apparatus a guarantee that current will not cost him more than 4 cents a kw-hr. if he charges batteries for others when asked.

Soennichsen Forms Parts Co.

MILWAUKEE, WIS., Nov. 4—A. M. Soennichsen, one of the founders of the Auto Parts Mfg. Co., Milwaukee, has resigned as general manager to organize the A. M. S. Co., this city, manufacturer of automobiles parts and accessories. G. W. Browne and T. C. McMillan are associated with Mr. Soennichsen. A factory is being established in the Manufacturers' Home Bldg., foot of Mason Street.

227,467 Registration in N. Y.

57,296 More Owners and Dealers Than in 1914—77,675 Chauffeurs

NEW YORK CITY, Nov. 6—Up to Nov. 1, 1915, there were registered in New York State 227,467 automobile owners and dealers and 77,675 chauffeurs as compared with 167,755 owners and dealers in the same period in 1914 with 64,326 chauffeurs. The receipts in 1915 were $1,860,050.50 as compared with $1,506,933.86 in 1914.

In the whole year of 1914 only 170,171 owners and dealers were registered with 67,170 chauffeurs. Receipts for that year amounted to $1,533,367.86.

	Owners and Dealers	Chauffeurs	Receipts
Nov. 1, 1915..	227,467	77,675	$1,860,050.50
Nov. 1, 1914..	167,755	64,326	1,506,933.86
Total, 1914...	170,171	67,170	1,533,367.86

Olds Reduces Eight $100

LANSING, MICH., Nov. 10—*Special Telegram*—The Olds Motor Works, this city, has reduced the price of its type 44 eight-cylinder car from $1,295 to $1,195. This car, which was described in THE AUTOMOBILE for Oct. 21, has a V-type eight-cylinder Northway motor with cylinders 2⅞ by 4¾, a 120-in. wheelbase, leather-faced cone clutch, floating axle, three-quarter elliptic springs, open driveshaft with two universals and three-speed gearset.

Studebaker Amplifies Territorial Work

DETROIT, MICH., Nov. 5—The Studebaker Corp. has provided a western and an eastern division in the office of the territorial manager. T. E. McMeans, formerly of the claims division, has been promoted to territorial manager for the western division, while W. C. Shanafelt retains the eastern district. To their duties has also been added that of looking after the service system.

Reliance Takes Saeger Engine

LANSING, MICH., Nov. 4—The Reliance Engineering Co. has taken over the Saeger Engine Works, and expects to greatly increase its production capacity of automobile parts. The Reliance company has been supplying a large amount of parts for the Chevrolet Motor Co., and it is rumored, but not confirmed, that the control of the Reliance company is now in the hands of the same interests who control the Chevrolet company.

650 Grant Cars a Month

FINDLAY, OHIO, Nov. 6—The Grant Motor Co., this city, is running on a regular spring schedule, producing about 650 cars per month, and orders for actual shipment and for storage by its larger dealers and distributors will absorb every car it can make up to March 1. From then on until the end of the season, the production will be largely augmented.

The company recently erected two large buildings for stock storage purposes, one 60 by 225 ft., the other 50 by 200 ft., and is about starting work on an addition to its final assembly plant, of a building aggregating 20,000 sq. ft.

War Order for Gersix

PORTLAND, ORE., Nov. 4—The Gerlinger Motor Car Co., this city, maker of the Gersix truck, has received large orders for export. This is the only six-cylinder truck made on the Pacific Coast. One of the warring nations has placed an order for ten trucks a month, commencing the first of the year.

Kokomo Companies Increase Facilities

KOKOMO, IND., Nov. 8—A large brick addition is being built by the Kokomo Brass Co., and associated companies, Byrne Kingston & Co., and the Kokomo Electric Co. These concerns are now supplying some of the largest concerns in the automobile and tractor industries.

Maxwell to Add 130,000 Sq. Ft.

DETROIT, MICH., Nov. 8—The plant of the Maxwell Motor Co. on Oakland Avenue, where the assembling and shipping departments are located, will be greatly enlarged. An additional factory building, one-story high, 130 by 1000 ft. with sawtooth roof will be erected, thus adding 130,000 sq. ft. of floorspace to the plant.

Auto Body to Buy Acme Plant?

LANSING, MICH., Nov. 5—The Auto Body Co., which has been expanding very rapidly during the last year, is reported to be negotiating with the Acme Engine Co. for the purchase of the latter's plant, which is located opposite that of the Auto Body Co.

G. V. Strike Settled

LONG ISLAND CITY, Nov. 5—The two weeks' strike of 550 employees of the General Vehicle Co., this city, for an eight-hour day instead of nine, has been ended. The strike was called in sympathy for the machinists on strike at Schenectady.

Walpole Creditors Receive Dividend

BOSTON, MASS., Nov. 5—The receivers of the Walpole Tire & Rubber Co. have been authorized to pay another dividend of 5 per cent by Judge Dodge in the United States District Court. This makes 90 per cent paid on claims allowed. The receivers expect to pay another dividend later. They have $200,000 on hand now.

Fight Glare Rule in St. Louis

Accessory Dealers Claim Ordinance Hurts Business and Increases Accidents

ST. LOUIS, MO., Nov. 6—Automobile men, especially accessory and supply dealers, are making loud and bitter complaint against the St. Louis anti-glare headlight law which they say is responsible for a decrease in their business as well as for the unusual number of automobile accidents which have occurred in this city since the dimmer ordinance went into effect.

The wholesale arrests of motorists whose lights did not comply with the new law, the accessory men say, have so frightened the owners of cars that many, ignorant of the exact requirements of the law, are operating their machines with dim lights, dash lights and in many cases without any lights.

To this they attribute the fact that the total of deaths caused by automobiles during the current year has been brought up to fifty-five and the injured to approximately 300 during the last few weeks. Last month alone twelve persons were killed by automobiles here and nearly a hundred injured. Those favoring the ordinance point out that the number of cars has increased 100 per cent, while accidents have increased only 33 per cent.

Insurance men have joined hands with the accessory dealers in condemning the ordinance which prohibits the use of lights whose rays are more than 3 ft. above ground at a distance of 75 ft. in front of the automobile. Companies which have placed liability insurance on automobiles have been besieged during the last few weeks as never before with claims for injury to persons and machines alike.

The law defeats its own purpose, in the opinion of the insurance and accessory men. It was adopted in the belief that dazzling headlights bewilder pedestrians and motorists coming from opposite directions. On the contrary, opponents of the law argue, glaring headlights served to warn pedestrians.

Shorter Hours for Mercer Men

TRENTON, N. J., Nov. 6—The Mercer Automobile Co., this city, is the second largest concern in Trenton to voluntarily grant its men a shorter week. The company will hereafter count fifty hours a week, instead of fifty-four as at present, and the wages will remain the same. About 350 machinists are employed. Last week the John R. Roebling's Sons Co. also reduced the working week of [illegible] chinists without any reductio[illegible]

Gasoline Goes Up 1 Cent

Both Standard Oil and Independents Advance Prices—Trouble in Georgia

NEW YORK CITY, Nov. 4—Another advance of 1 cent occurred last week in the gasoline field. Garages in New York City are charging owners 22 cents a gal., an advance of 1 cent a gallon. During the summer the low price was 16 cents. The price of gasoline in northern New Jersey to the owner has been increased 1 cent to 19 cents by the gasoline delivery wagons.

Philadelphia gasoline has been advanced 1 cent, to 15 cents a gallon. Boston gasoline also received a 1 cent advance and is now quoting at 19 cents on the tank wagon basis. Standard Oil in that city has advanced the price 1 cent to 19 cents, tank wagon basis, meeting the earlier advance of the independents.

The Standard Oil of Nebraska has advanced the price of gasoline on tank wagon basis to 13 cents a gallon and has made corresponding advances throughout its entire territory. In Omaha, the price has been advanced ½ cent to 13 cents, tank wagon basis. The last thirty days has seen a rise from 10 cents, the low price this summer, and in fact the low price since March.

The S. O. of Kentucky has advanced gasoline prices 1 cent to 14½ cents, tank wagons and garage basis.

At Nashville S. O. now quotes at 16 cents a gallon to garages and 16 cents in lots of less than 100 gal. The Gulf Refining quotes the straight price of 17 cents. The price last March was 10 cents a gallon.

The independents have advanced their price 1 cent to 11.8 cents a gallon, tank wagon basis. This meets the price of the S. O. which has not been changed since the last previous advance.

The Atlantic Refining Co. in Pittsburgh, has advanced gasoline 1 cent a gallon to owners. Gasoline is now quoted at 17 cents a gallon, 68-70 deg., 19 cents, and 76 deg. at 12 cents. The prices on March 31 were 9 cents, 11 cents and 13 cents respectively.

In Detroit, gasoline is selling at 13 cents at practically all filling stations and garages, whether received from S. O. or some other company. This is an increase of 1 cent over the former price, which itself had been raised 1 cent, from 11 to 12 cents.

—

Georgia to Prosecute Gasoline Dealers

ATLANTA, GA., Nov. 4—Between fifty and seventy-five retail and wholesale dealers in gasoline located in several Georgia cities are to be prosecuted by the state department of agriculture for violation of the State law which forbids the misbranding of gasoline as to the specific gravity of same.

This law requires that all retailers shall post signs, showing the specific gravity, and it is understood that some of the prosecutions will be for failure to brand at all.

—

Higher Market Prices

NEW YORK CITY, Nov. 9—Prices in metals, lubricants and rubber last week were higher. The metals, after a substantial gain the previous week, made a new record when all the products listed under that head, made gains. Copper, aluminum, Bessemer and Open-Hearth steel and lead featured the market. Crude rubber was stronger with a 2-cent rise. This was due in the main to a stronger market in London and reports of a firmer situation in Brazil. The demand was more active, though manufacturers, as a rule, were disposed to restrict their purchases to moderate lots.

The oils and lubricants market was stronger last week. Gasoline prices in general are higher. Yesterday, New York gasoline went up to 18 cents a gallon in steel barrels. Pennsylvania crude petroleum saw a rise of 5 cents a barrel. Lard oil closed yesterday at 92 cents with a gain of 7 cents for the week.

October Shipments 15,972 Carloads

NEW YORK CITY, Nov. 5—At the regular monthly meeting of the National Board of Directors of the National Automobile Chamber of Commerce, Inc., held at the headquarters of the Chamber here yesterday, the Traffic Committee reported that October shipments of automobiles amounted to 15,972 carloads as compared with 10,443 carloads shipped in October, 1914, or an increase of over 50 per cent. In September of this year shipments amounted to 17,190 carloads.

Automobile shipments for the past year for each month are as follows:

1914	
October	10,433
November	6,719
December	6,378
1915	
January	8,369
February	11,273
March	16,442

Continental $416,000 Dividend

DETROIT, MICH., Nov. 4—Papers were filed with the County Clerk by the Continental Motor Mfg. Co. showing that in addition to the increase of its capital stock from $2,400,000 to $2,900,000, a stock dividend of $416,000 was declared which goes to present stockholders. Of the new capital stock of the company, $900,000 is preferred and it will be subject to redemption at par, Oct. 1, 1932. It may, however, also be redeemed before that date at $105 per share, plus accumulated dividends, after sixty days notice to holders.

—

Chandler Stock Oversubscribed

NEW YORK CITY, Nov. 5—So eager have subscribers been for the increased issue of common stock of the Chandler Motor Car Co., which was listed at 85, that the total amount was oversubscribed a dozen times at the date of closing the subscriptions. This oversubscription was largely due to the fa-

vorable financial standing of the company, which for the nine months ending September, showed a profit of $950,000 earnings on stock, and it is estimated that the net earnings for the calendar year will be in excess of $1,000,000. F. C. Chandler, president of the company, states that the company has at present $690,000 in cash, which will be increased by the new money going into the concern to $1,786,000. The only liabilities are $125,000 current bills not due. President Chandler estimates the earnings for the coming year at approximately $2,000,000.

Gray-Dort Co. to Make Cars in Canada

CHATHAM, ONT., Nov. 6—Capitalized at $500,000 of which $300,000 is paid up, the Gray-Dort Automobile Co. has been organized here to make the Canadian Dort cars.

Robert Gray, of the Gray-Campbell Co. and J. D. Dort, who has been president of the Dort Motor Car Co., Flint, Mich., are the heads of the new company. F. Knight will be superintendent. Frank Averill has also come here from Flint to join the new organization.

Remsen Heads N. A. C. C. Committee

DETROIT, MICH., Nov. 2—The National Automobile Chamber of Commerce has named A. H. Remsen, assistant office manager of the Studebaker Corp. as chairman of the repair parts policy committee of the chamber.

Dividends Declared

Pratt & Whitney Co.; quarterly 1½ per cent on preferred, payable Nov. 15.

Maxwell Motor Co. quarterly, 1¾ per cent on preferred.

Security Prices Lower

War Stocks Drop — Reactionary Tendency Starts—Tire Issues Fairly Strong

NEW YORK CITY, Nov. 10—Motor stocks have suffered heavily in the last ten days, General Motors dropping 22 points; Maxwell 19; and Willys-Overland 45, the heavy losses being generally due to reactionary tendency that set in over two weeks ago. Practically all motor stocks have sold off while railroad stocks have shown perceptible gains.

These and other stocks which have been making phenomenal rises since July 29 are now suffering a few similar setbacks. Yesterday General Motors dropped 20 points; Studebaker 21; Maxwell 12, and Overland 21. The present price of these four leaders in the motor stock market is still high compared with Aug. 1, at which time General Motors was 203 and it is now 370. At that time Studebaker was 83¾ and is now 215. Maxwell was 36 and is 65½. Overland was 147 and is 215. There is nothing unusual in the declining prices in these stocks in the last few days, the drops being due to some of the holders trying to realize the heavy profits they have made in the last few weeks.

Most important in the motor stocks is the new issue of Willys-Overland consisting of $15,000,000 out of an authorized $25,000,000 of new convertible 7 per cent preferred stock to be offered to holders of common at 102½ to the extent of 71½ per cent of their holdings.

Portage Rubber and Peerless featured the market last week. The former stock closed on Saturday at 80 with a net gain of 20½ points. Its security rose to 98 with a gain of 4 points. Portage officials expect this fiscal year to duplicate the record of the preceding twelve months, when 15 per cent was made for common. The company has no war business; it is increasing capacity by a small addition, and when that is completed will be able to turn out 600 tires a day. It is reported that sales for 1916 are looming up 100 per cent greater than those for 1915. Peerless common went up 25¼ points, closing at 147¼.

Chalmers common went up 6 points. This stock, it is said, will be put on an annual dividend basis of $12 a share early next year. Profits the current fiscal year are said to be equal to about $30 a share on the common, which has been paying yearly dividends of $10 a share for four years.

Quotations in the Detroit markets were generally higher. Paige-Detroit kept up its rise, this week going up 15 points. General Motors, after dropping 16 points the previous week, rose 18 points, closing at 370.

700 Trucks Sold to France

NEW YORK CITY, Nov. 10—Sales of motor trucks last week to the French government totalled approximately 700 trucks. The companies from whom the purchases were made has not been announced. The trucks were of the conventional sizes that the government has been purchasing for the past year.

100,000 See Los Angeles Show

78,000 Paid Admissions at Dealers' Assn. Exhibit —Many Cars Sold

LOS ANGELES, CAL., Nov. 1—Credit for California's most successful automobile show must go to the Motor Car Dealers' Association of Los Angeles. A show has at last been staged on the Pacific Coast which ranks with the salons of the East.

The great Broadway Automobile and Flower Show, which came to a close at midnight last night, eclipses anything of the kind ever before attempted on the Pacific Slope. Not only was the Broadway Automobile and Flower Show a great success from the standpoint of the dealer selling at retail, but an overwhelming success from the standpoint of the distributor. There were 78,000 paid admissions. It is claimed that a quarter of these were prospects as only those interested in motor cars attended the show. Including passes 100,000 attended the salon.

Pleasure cars only were exhibited. Floorspace sold for fifty cents per square foot. Many firms were unable to secure space the last ten days before the opening of the show. The expenses of the show were heavy; but with several thousand dollars cleared for the association, another show under the same auspices is assured for next season.

The last week in October seems to be the best time for a show in Los Angeles. The orange growers who purchase cars annually in southern California to the amount of about $5,000,000 have their money in the banks for the last year's crops and are able to judge what the crops will be for the coming season. The walnut growers have just finished harvesting their crops. The beet and bean growers have their money and the motion picture people who buy cars in great numbers each year, have returned from their vacations and are looking for the latest models to spring at the holiday season.

Los Angeles to Have Permanent Used-Car Show

LOS ANGELES, CAL., Nov. 4—The largest tent in the world houses the latest novelty of the automobile industry established in Los Angeles. It is a used car show. The tent has a capacity of 5000 persons and 500 cars, the show being for the purpose of displaying for sale and exchange the largest supply of automobiles ever housed under one roof.

For many months, there has been a great used car business carried on within a short distance of the heart of the city on vacant lots. Realizing that this business will suffer from the winter rains and that there is a great deal of business to be done after dark, the Union Auto Bus Co., a California corporation with a capital of $75,000, has erected the great tent and will operate the used car show, auctions, sales and exchanges. Real estate is also exchanged for cars and cars for real estate.

A gasoline and oil station is operated on the grounds. In another side tent there is a restaurant. There is also a tent given over to a large accessory stock and another canvas top houses a garage and repair shop.

Inside the main tent there is a large circular track for demonstrating purposes. There is also an elevated runway in the center of the track for testing brakes, gears and motors. This elevated bridge will also be used at the weekly auction as the "block."

These auctions are to be held each Saturday. Cars are entered in the market place for the sum of $1.

—

Connecticut Saxon Owners to Organize

NEW HAVEN, CONN., Nov. 6—Plans are under way to form the Connecticut Saxon Society comprising owners of that make of cars throughout the State. The idea is to have all Saxon owners who visit the New York show register there and be entertained by the factory officials, and next summer there is planned an entire day's outing at Savin Rock. One of the features also planned is to have some skilled factory mechanics on hand to give demonstrations to owners how they may repair their cars and get the best service from the machines.

—

Studebaker Officials Reach New York

NEW YORK CITY, Nov. 9—A Studebaker business conference was held at Hotel Astor to-day where 150 dealers under the jurisdiction of the local branch met to listen to talks by the factory heads, who are making a tour of the branches throughout the country.

Develop Community Garage

Promoters to Sell One Share Only to Each Automobilist —To Provide Service

MILWAUKEE, WIS., Nov. 6—A community garage and supply system that is likely to furnish a model for other sparsely settled sections of the country is being worked out in Jackson County, Wis.

A number of business men of Black River Falls, have conceived the idea of organizing the 500 motorists of the county into a corporation for mutual benefit. The corporation is to build a garage and supply store which will also serve as clubhouse, and the wants and requirements of all members can thus be met in metropolitan fashion. The garage is to employ competent mechanical help and be prepared to repair, wash and overhaul cars of members at reasonable prices. Supplies will also be sold. It is also the intention of the corporation to act as selling agent for every automobile dealer who becomes a member of the association.

The corporation is to be incorporated with $15,000 capital, divided into 600 shares at $25 par value. A permanent organization is to be perfected on or about Dec. 15. R. P. Rainey and F. A. Parsons of Black River Falls are now canvassing all owners in the county for stock subscriptions, and it is the plan of the promoters to sell only one share to any one individual to make the corporation a true co-operative association.

—

Miles Goes to Chicago

NEW YORK CITY, Nov. 6—Samuel A. Miles, general manager of the national automobile shows at New York and Chicago, has gone to the latter city to make the preliminary arrangements for holding the big exhibition Jan. 22-29.

—

Try Semaphores in Chicago

CHICAGO, ILL., Nov. 5—A street semaphore for controlling Chicago traffic is being tried out at the intersection of two of the busiest thoroughfares of the city. This is of the conventional Stop-and-Go type and on the top is a combination red and green light similar to the type used for railroad switch signals. The red shows, for instance, north and south while the green shows east and west. Whether or not the semaphore will be definitely adopted on Chicago boulevards has not been determined as yet, but the trial is proving that this particular instrument undergoing test does not place the signal sufficiently high. It is only 8 ft. above the street and high limousines and cars with tops up obstruct the view

of the signal from those in following cars. It also is thought the letters are not large enough to be readily seen at sufficient distance. Another and temporary objection to the semaphore is the fact that Chicago motorists have become educated to listening to the whistle rather than looking for a visible signal and some of them the first day or two have failed to observe the signal at all.

St. Joseph to Have $2,000,000 Speedway

SAINT JOSEPH, MO., Nov. 4—Saint Joseph is to have a $2,000,000 2-mile speedway. Land for the building of a speedway at Lake Contrary, in the southern limits of the city, was donated by holders of concessions at that place.

Preliminary work will begin at once and the first races will be held early next spring.

Dealers Score in Separator Fight

NEW YORK CITY, Nov. 10—The Automobile Dealers Association of New York City, has won an important step in its fight with the fire department against the use of oil separators in garages. Recently the fire commissioner refused to grant a permit to a certain garage on the ground that it did not have an oil separator. On this action being taken the dealers asked for an order of mandamus requiring the fire commissioner to grant a permit. The Supreme Court, before which this action was brought, has ordered that the entire matter be heard before a jury, at which hearing the questions of fact with regard to the necessity of oil separators will be determined.

Another Ahlberg Bearing Branch

MINNEAPOLIS, MINN., Nov. 6—The Ahlberg Bearing Co., Chicago, Ill., has opened a branch office and exchange agency at 926 Marquette Avenue, this city, placing L. J. Bohan as branch manager. The company now has branches in New York, Boston, Cleveland, Detroit, St. Louis, and Los Angeles.

Vesuvius Plug Cheaper to Dealers

NEW YORK CITY, Nov. 8—The price to the dealer of the Vesuvius spark plug made by A. R. Mosler & Co., has been reduced from 75 to 55 cents; this is a 20-cent increase in profit, for the plug will still retail at $1. At the same time the price to the jobber has been reduced from 60 to 40 cents.

Rueschaw in New York

NEW YORK CITY, Nov. 10—R. C. Rueschaw, sales manager of the Reo Motor Car Co., arrived in this city yesterday on a swing around the country. He has been in the far West and on the Northwest coast recently. He states that demands for cars are unprecedented, especially in Canada.

Woman Wins Maxwell Efficiency

33.37 M. P. G. Not Highest Average, But She Did Not Take on Supplies

DETROIT, MICH., Nov. 8—By driving from Buffalo to Haverhill, Mass., a distance of 567 miles, without taking on extra gasoline or oil on the road and thus averaging 33.37 miles to the gallon, her consumption being 17 gal., Miss Eva Cunningham was declared the winner in the Maxwell Dealers' Efficiency Run, which started from Buffalo Sept. 28 and continued for several days after, or until the contestant had reached his home town.

The test or run was part of the convention of the Maxwell dealers of zone No. 1, which includes the New England States, New Jersey, New York, Maryland and eastern Pennsylvania, the dealers taking delivery of new Maxwell cars at the plant in Detroit and starting the home drive from Buffalo.

About 100 started, but owing to the bad roads in many parts of the country through which some had to drive they either gave up the contest or did not care to be considered as contestants. About thirty sent in their sworn affidavits showing exactly what they had done, and from the reports it was seen that the test was in many instances a most severe one.

Two contestants, F. J. Cunningham, Haverhill, Mass., and George D. Robinson, Springfield, Mass., averaged better than the winner, the former covering a distance of 516 miles on 14 gal., thus averaging 36.85 miles to the gallon while Robinson consumed 13 gal. of gasoline to cover 453.8 miles, or an average of 34.90 miles to the gallon. Both of these contestants, however, took on an extra supply of oil during the run while the winner did not take any extra supply and for this reason she was declared the winner.

Louis Nikrent with Chevrolet

LOS ANGELES, CAL., Nov. 5—Louis Nikrent, until recently a member of the Mercer racing team, has given up racing and is now in charge of the service department of the Los Angeles branch of the Chevrolet Motor Co. of California.

115 Studebakers on Four-Day Run

DETROIT, MICH., Nov. 8—To-day 115 Studebaker cars started in different parts of the country on a four-day reliability tour promoted by the Studebaker Corp., the contestants being principally dealers and distributors of Studebaker cars. The start was made as near as possible at 6 a. m., the day's run being over a course of about 250 miles. All cars used are either fours or sixes, standard stock, with full touring equipment, and carrying the number of passengers for which the car is designed. An observer in every car will keep track of happenings on the road. A record of the gasoline and oil consumption will be kept. The total distance of 1000 miles to be run in the four days is to be covered as nearly as possible in 48 hr. of actual running time. The tour has been arranged to get a gasoline and oil consumption record under ordinary touring conditions throughout the country.

Duffy Gets Standard in New York

NEW YORK CITY, Nov. 6—A Standard agency has been opened in New York by the Duffy Motors Corp., factory distributor in New York, New Jersey and Connecticut. The company has leased the property on the southwest corner of Broadway and Sixty-third Street for its show rooms and also has obtained adequate service facilities in the immediate neighborhood.

The Standard Steel Car Co., Pittsburgh, Pa., has been making automobiles for nearly three years.

Lavine Gear Not Reorganized

NEW YORK CITY, Nov. 5—In THE AUTOMOBILE for Oct. 28 it was stated that D. L. Robertson is secretary of the reorganized Lavine Gear Co., Racine, Wis., and that President Uihlein of the company is a member of the family owning the Schlitz Brewing Co. of Milwaukee. These statements were in error, Mr. Robertson being office manager and purchasing agent of the company, which has undergone no reorganization, while Mr. Uihlein has no connection whatever with the Schlitz brewery.

No Truck Show for Philadelphia

PHILADELPHIA, PA., Nov. 5—At a recent meeting of the board of governors of the Philadelphia Motor Truck Association it was decided not to hold a show the week after the annual show of the local automobile trade association. Several of the commercial vehicle agencies in Philadelphia will hold independent exhibitions in their establishments.

Traffic Law for Pedestrians

NEW YORK CITY, Nov. 6—The Street Traffic Society of the Safety First Society at a meeting recently decided that for the better safeguarding of pedestrians greater authority should be given to the traffic police to regulate and direct foot travel upon the public streets and that it should be unlawful for any person to cross a street in the middle of a block.

Factory Miscellany

To Make Automobile Spokes—Elrod & Co., Columbia, Ky., will establish a plant at Erwin, Tenn., to make automobile spokes and other stock. A building has been secured.

Toledo Light Co. Adds—The Electric Auto-Lite Co., Toledo, Ohio, will erect a concrete and steel addition, 103 by 385 ft., three stories. The company makes lamps, horns and other accessories.

Atlas Brass Adds—The Atlas Brass Co. plans a large addition to the plant, located on South Park Street, Columbus, Ohio. The company has found a large increase in business by the manufacture of automobile parts and accessories.

Bowser Adds—The foundation for a new three-story building to serve as vault has been laid by the Bowser company of Fort Wayne, Ind., and the building will be completed as soon as possible. It will be about 25 by 40 ft., and will be of absolutely fireproof construction, as all valuable papers of the company will be placed in it. Work on other buildings at the Bowser plant is progressing rapidly. The fireproof testing building is nearly completed.

Gisholt Machine in New Plant—The Gisholt Machine Co., Madison, Wis., turret lathes and other machine tools, has taken occupancy of the $40,000 addition erected because the rush of business crowded the former quarters to the utmost limit of capacity. The new building affords 25,000 sq. ft. of floor space. Approximately the same space has been added by the leasing of adjoining factory buildings recently vacated by the General Electric Co.

Clayton & Lambert Increase Force—The Clayton & Lambert Mfg. Co., Detroit, Mich., which makes automobile sheet metal parts and sheet metal stampings, will increase its working force from 500 to 1000 men or more. Additions to the plant are being completed and additional machinery and equipment is being installed. The business of the concern is said to have increased over 50 per cent during the last few months. More orders are on the books now than ever before.

Vulcanized Products' Addition Completed—The Vulcanized Products Co., Muskegon, Mich., new addition was completed a few days ago and the manufacturing of inner tubes has started. Within a fortnight the manufacturing of casings will also be started. When the plant will be in full operation it is expected that 200 complete tires will be made daily. Fifty more men are being added to the working force, it being the intention of the company to gradually expend and produce tires on a large scale. W. N. McDonald is factory manager.

Marathon Tire Warehouse in Omaha—The Marathon Tire & Rubber Co. is at present negotiating for the establishment of a warehouse in Omaha. This will in no way interfere with their present distributors or alter their sales plans. The establishment of the warehouse is to facilitate shipments to its distributors in that section of the country.

H. H. Replogle has been appointed manager of the middle west division with headquarters at Omaha.

No merchandise will be sold at retail from the warehouse. The local retail business will be handled by the Akron-Marathon Rubber Co. and its sub-agents.

Safety Engineers Meet at Philadelphia—Interesting and instructive addresses were given by safety engineers, in conjunction with numerous charts, photographs and devices, at the fourth annual congress of the National Safety Council, held Oct. 19, 20 and 21, at the Bellevue-Stratford Hotel, Philadelphia, Pa. Points on safety to workmen and methods of sanitation in industrial plants, whether woodworking, textile or automobile, were ably brought out by the various speakers, each versed in his particular line of work. The automobile industry is represented on the board of directors by J. M. Eaton of the Cadillac Motor Car Co., Detroit, and L. B. Robertson of the Ford Motor Co., Detroit.

The Week in the Industry

Robbins Chalmers Portland Representative—J. M. Robbins, formerly of Denver, has been appointed Chalmers representative in Portland, Ore., succeeding Marc Bunnell, at present in San Francisco.

Weidely Heads Los Angeles Pathfinder—W. A. Weidely, son of George A. Weidely, motor manufacturer, has been appointed manager of the Los Angeles Pathfinder branch, which serves the entire southern California and Arizona territory.

Gallagher Goes to Chicago—Jos. A. Gallagher, for many years with the Autocar company and the Swinehart Tire & Rubber Co., has been appointed branch manager for the American Taximeter Co., New York City, in Chicago.

Blanchard Makes Change—William Blanchard, who was prominent in the affairs of the Lenox Motor Car Co., Boston, Mass., acting as sales manager and treasurer, has resigned, and he is now sales manager of the Cunningham Motor Car Co. in that city.

Clemens Heads Detroiter Branch—The Detroiter Motor Car Co., Detroit, Mich., has opened branch sales rooms at 676 Woodward Avenue. The factory branch has been placed in charge of W. J. Clemens. Mr. Clemens disposed of the Clemens Motor Sales Co. in Buffalo, N. Y., in order to form his present connection with the Detroiter company.

Coburn Heads New Boston Maxwell—The Coburn-Draper Motor Co. was organized at Boston, Mass., last week to take over the retailing of the Maxwell in that city that the J. W. Bowman Co. gave up. The new company has leased one-half of the Peerless Building at 660 Beacon Street, where it will have sales and service station. Ralph Coburn, who has been identified with the Maxwell for eleven years, and was manager of the New England wholesale branch, is president and W. H. Draper of Providence, treasurer. S. W. Munroe has been sent on from the Detroit factory to take charge of the wholesale branch.

—

Dealer

Handling Car Refinishing Paste—The Auto Lacker Sales Co., Denver, Col., has established a branch office at St. Louis, in the Wainwright Building. A. J. Short and C. A. Smith are in charge of the local office. The company's product is a paste which when mixed with water is used as a refinisher for automobiles.

Motor Men in New Roles

Tiffany Detroit McGraw Tire Manager—G. W. Tiffany has been appointed manager of the Detroit branch of McGraw Tire & Rubber Co., East Palestine, Ohio.

Chase Joins Anderson Electric—E. H. Chase, Jr., has become a traveling salesman for the Anderson Electric Car Co., Detroit, Mich. His headquarters will be in Philadelphia.

Frazier Goes to St. Louis—P. G. Frazier, formerly with the Philadelphia branch of the Kelly-Springfield Tire Co., has taken charge of the St. Louis, Mo., branch of the same company as manager succeeding H. L. Smith.

Connick Goes to Los Angeles—H. J. Connick, former Chevrolet dealer at Greenville, S. C., has been appointed supervisor of agencies for the southern California district, making his headquarters in Los Angeles, Cal.

Tucker Service Manager—C. H. Tucker, formerly service manager of the Cole Automobile Co. of Missouri, has been appointed service manager of the De Luxe Automobile Co., St. Louis distributor of Oldsmobile and Metz cars.

Sanborn Heads Detroit Branch—A branch has been established at Twelfth Street and the G. T. R. R., Detroit, Mich., by the Booth Felt Co., Brooklyn, N. Y., felt manufacturers. The branch is in charge of M. R. Sanborn.

Barrabee Forms Own Company—S. L. Barrabee, for some years a partner of the Brophy-Barrabee Co., one of the big accessory firms at Boston, Mass., has retired from the firm and gone into business for himself at 133 Columbus Avenue. His brother Frank has joined him.

Huyck Makes Change—Edgar Huyck, formerly with the Hendie tire factory at Torrance, Cal., has opened a tire and repair establishment at 772 East Third Street, San Bernardino, Cal., with Boyd Hocker, manager of the Pomona Valley Canning Co., Pomona, as a business associate.

Hill Cadillac Representative—F. J. Hill, formerly with the Hupp Motor Car Co., Detroit, Mich., has been appointed southwestern representative of the Cadillac Motor Car Co. His territory will include Georgia, Florida, Alabama, Mississippi, South Carolina, parts of Tennessee and Louisiana.

Holloway Heads Frisco Saxon—R. E. Hollaway, formerly with the H. O. Harrison Co., San Francisco, has been appointed general manager of the Saxon Sales Co., with headquarters in San Francisco. This company will distribute Saxon cars in the Northern California territory, taking over the Saxon agency from the Pearson-Saxon Co.

Apger in Garage Business—H. C. Apger, who until recently was with the Pacific Kissel Kar Branch at Los Angeles in the capacity of sales manager, has purchased the Corner Garage, located in Huntington Park, Cal., formerly owned and operated by the firm of Moore & Stringer. J. F. Smith, former service manager with the Kissel Kar branch in Los Angeles, is associated with Apger.

Tetzlaff Makes Change—Teddy Tetzlaff, formerly with the Lord Motor Car Co., in the capacity of supervisor of agencies throughout Arizona and southern California for the Maxwell, is now with the Harold L. Arnold organization, Dodge and Hudson distributors. The former speed king's new title is district booster salesman. He is to spend his time out with the sub-dealers as an efficiency man.

Ackerson Transferred—C. L. Ackerson, recently manager of the Winnipeg branch of the Maxwell Motor Co., Detroit, has been transferred to Windsor, Ont., where he will make his headquarters and take over the duties of general sales manager for Canada. F. W. Wilkins, recently manager for Saskatchewan, has been transferred to Winnipeg, and will have charge of sales in the western district.

Duffee Makes Change—E. L. Duffee, who has been manager of the New York branch of the Midgley Tire & Rubber Co., Lancaster, Ohio, since the opening of this office some months ago, has been recalled to the home office, where his services are required in another capacity.

E. S. Benson, recently with the Hartford Rubber Works, Hartford, Conn., is now manager of the New York branch of the above company.

—

Dealer

Hartford Auto Parts Moves—The Hartford Auto Parts Co., Hartford, Conn., which was forced out of the Colt's west armory by the expansion of the latter concern, has taken a portion of the old Cheney silk mill on Morgan Street. Some time ago the company announced that it would remove to New Britain, where a satisfactory proposition was made by those interested in the company. For a time at least the company will remain in Hartford.

Trade News from Wash.—Lou Schabel, 1302-6 South E Street, Tacoma, Wash., has secured the agency for Swinehart tires.

The Thompson Lubricating Co., Tacoma, has secured the agency for Savage tires.

The Seven Seven Co., Spokane, Wash., and Inland Empire distributor of Dodge cars, has moved into its new garage, at First and Adams Streets.

New Willard Service Stations.—The Willard Storage Battery Co., Cleveland, has added the following service stations to its list: Edward E. North, Warren, Ohio; E. B. Vivian, Monroe, Mich.; The Sleeper Co., Fowler, Ind.; Oriental Auto Co., Chanute, Kan.; Meredith Battery Service Station, Springfield, Mo.; Iowa Battery Service Station, Hampton, Iowa; and Lebanon Storage Battery & Magneto Co., Lebanon, Pa.

Large U. S. Tire Deal—What is said to be one of the biggest tire deals ever closed was effected here this week between the United States Tire Co. and the Simmons Hardware Co., St. Louis. According to officials of the tire company the transaction involved a million dollars' worth of tires. Hereafter the Simmons company and its branch houses in Philadelphia, Toledo, Memphis, Wichita, Kan., and Sioux City, Iowa, will distribute United States tires.

Gas Engine Efficiency Reincorporates—The Gas Engine Efficiency Co., St. Louis, has reincorporated and hereafter will be known as the Efficiency Oil Corp. The incorporators are President Edward Sterns, O. L. Menzing and C. B. Hollister. A retail sales room has been opened at 3213 Locust Street with Hollister in charge. The company manufactures a product which is mixed with the gasoline so as to provide cylinder lubrication.

Late Texas Trade News.—C. H. Gray Rubber Co., Dallas, Tex., has added the Silver King and Blackstone tires.

The Herff-Brooks Automobile Co., Dallas, has been organized by W. C. Blanchard, Dallas, and J. A. Dinwiddle of Fort Worth. Temporary quarters are in the Linz Building.

The Ilseng Motor Car Co., Fort Worth, State distributor for the Monroe, has opened offices at 236 Commerce Street. H. Lester is in charge.

Trade Items from Missouri.—The Sears-Cross Spedindicator has opened a branch office in Kansas City at 205-7 East Eighteenth Street, Kansas City, Mo., under the management of Ed. S. Michelson. A complete branch and service station has been established.

The National Motor Car Co. is now operating a garage at 310 Boonville Street, Springfield, Mo., in a building extensively remodeled for the purpose. Lee A. Patterson is manager, being associated with Dixon Brothers in the operation of the garage.

The district branch and service station of the Hartford Suspension Co., Kansas City, Mo., has been moved to more convenient quarters, with better equipment, at 207 East Eighteenth Street. It formerly was at 1803 Grand Avenue.

Los Angeles Items.—The Kay & Burbank Co., Los Angeles, Cal., has opened a large Delco service station at 1101-3-5-7 South Figuroa Street. In addition to an extensive business as Delco specialists the concern is one of the largest Exide battery depots on the Pacific slope.

J. S. Bushby has opened a garage at 710 West Eleventh Street, making a specialty of Packard and Chalmers repair work.

H. G. Pendell, 1239-51 South Figuroa Street, has been appointed district distributor of Zenith carburetors. Pendell also handles the Commerce and Atterbury truck lines.

Milwaukee News.—The Storage Battery Service Co., organized recently in Milwaukee by C. F. Seifert and W. W. Zeige, has been appointed distributor of Exide batteries. Headquarters are at 137 Oneida Street.

The Philip Gross Hardware Co., 218-220 Third Street, has been appointed distributor of Eveready storage batteries, manufactured by the American Ever Ready Works of the National Carbon Co.

Lando L. Albert, for five years associated with the Hickman-Lauson-Diener Motor Car Co., then State agent for the Ford, has established a Ford repair shop at 187 Oneida Street and is making a specialty of repairs on this make.

An official service station for the Stewart-Warner Speedometer Corp. has been established at 182 Fifth Street, under the name of Speedometer Service & Supply Co.

The Dayton Rubber Sales Co., 415 Cedar Street, has taken the agency for the W. & C. shock absorber for Ford cars, manufactured by Phil. H. Webber & Co., Hoopeston, Ill.

Baltimore Trade Items—J. R. M. Adams, Franklin and Eutaw Streets, Baltimore, has entered the automobile business, as the representative of the Sphinx car. The firm for some time has been handling accessories.

The Baltimore Sewed Tire Co. has leased property at 522 North Eutaw Street, and expects to get into operation at once. C. E. Erdman, G. B. E. Erdman and L. D. Pritchard comprise the firm. In conjunction with the tire renewal business the new concern will handle automobile accessories and will be equipped to handle tire repairing and vulcanizing.

The Double Mileage Tire Co., Inc., 533 North Howard Street, is in charge of Earle E. Ramsdell, general manager. The headquarters of the firm is Buffalo, N. Y. The firm makes a new 4000-mile tire out of two old ones.

The Perfek Device Co., 535 West Baltimore Street, is placing a carbon remover and gasoline saver on the market.

Maurice L. Knight, 1025 West Mulberry Street, is manufacturing dimmers.

The Southern Engineering Corp., 223 West Saratoga Street, will handle a full line of supplies.

Oliver Garage & Machine Co., 1439 North Central Avenue, is now equipped for general repairing and the selling of accessories, as well as in a position to handle storing and hiring.

F. M. Schwalm, 329 Title Building, Baltimore, is the distributor for Maryland of Gaso-Tonic.

Recent Minneapolis Additions—Bohn E. Fawkes, representing the Oldsmobile in this territory, will erect at once a $40,000 brick, terra cotta and glass building at Hennepin Avenue and Harmon Place. The structure will be three stories. L. H. Fawkes of the Fawkes Auto Co. has bought an adjoining tract for $20,000 and will erect an automobile building.

The Ahlberg Bearings Co. of Chicago has opened a branch at 926 Marquette Avenue for sale of annular thrusts and double row and Rodax bearings.

Accessory House for Winnipeg—The Alfred Maw Motor Co. has opened in Winnipeg, Man., and will handle automobile accessories and will make arrangements to handle agencies for a low and medium-priced line of cars. The headquarters are at 417 Portage Avenue.

Electric Products Opens N. Y. Office—The Electric Products Co., Cleveland, Ohio, has opened its Eastern branch office at 30 East Forty-second Street, New York City, in charge of F. W. Eller and J. P. Lyons.

Louisville Agent Moves—The Motor Sales Co., Louisville agent for the Stearns and Saxon, has moved its office and salesroom from 728 South Fourth Street to 931 South Third Avenue.

M. & S. Gear in Canada—The Canadian Fairbanks-Morse Co., with branch houses in all of the important cities throughout the Dominion of Canada, has closed a contract with the M. & S. Gear Co., Detroit, to act as the Canadian distributor for the M. & S. differential.

Moon Agency in Central America—E. H. Serrano of Havana, Cuba, has made arrangements to handle the Moon car in Central America.

Will Repair Radiators—A radiator hospital and factory has been opened by W. C. Craig and F. L. Wilson of Tulsa, Okla., at 422 Bond Avenue, N. W., Grand Rapids, Mich. The men will make a specialty of repair work on radiators. At present they conduct a similar establishment in Tulsa.

Ford Service in Yonkers—The fiftieth sales and service branch of the Ford Motor Co., Detroit, Mich., has been opened by the company in Yonkers, N. Y. Several others are being planned, but arrangements have not progressed to the point where a definite announcement can be made at this time.

Trade News from Spokane—The Oldsmobile Co., Spokane, Wash., Inland Empire distributor for the Oldsmobile has closed a contract to handle in addition the Denby truck in the same territory, which includes all of Washington east of the Cascades, and practically all of Idaho, including the Boise territory. Frank Liddell will have charge of the truck department.

The Seven-Seven Co., Dodge distributor, has recently taken the agency for Kelly-Springfield tires, and has appointed sub-agents for the tires at all of the principal towns of the Inland Empire.

W. J. Ball Motors Co. has become the Inland Empire, distributor for Pierce-Arrow cars and truck.

Eclipse Spark Plugs in Detroit—The Cutting, Armstrong & Smith Sales Co., Detroit, Mich., has been appointed representative for the Eclipse Mfg. Co., Indianapolis, Ind., manufacturer of the Giant and Hercules spark plugs.

Takes Ideal Jack Agency—The Auto Device Sales Co., 139 Oneida Street, Milwaukee, has taken the agency for the Ideal automatic jack for the state of Wisconsin. The company is a large jobber and retailer of specialties, including the Adco shock absorber, manufactured by the Auto Device Mfg. Co. of Milwaukee.

Late Iowa News Items—Splinter & Holscher, garage proprietors at Earlville, Iowa, are installing a modern electric generating outfit for the charging of automobile storage batteries. They also are adding a large lathe to the equipment of their garage.

G. A. McLoney and J. E. Bigler of Moberly, Mo., have bought the Overland Garage at Keokuk, Iowa, and will continue it under the old name. Both are experienced men. Overland cars and fixtures are a specialty and expert machinists will handle an extensive repair business.

R. W. Phelps of Tipton, Iowa, has leased the Ross Building in that city and will establish an exclusive Ford garage, where Ford cars and accessories only will be carried. It will be known as the Phelps Motor Co.

John Hanson and John Hadley of the Waterloo Overland Co. have approved plans and specifications for a new four-story Overland garage and district headquarters at East Fourth and Franklin streets, Waterloo, Ia.

Philadelphia News Items—The Packard Motor Car Co., Philadelphia, has extended to its employees the privilege of acquiring military instruction at the recently organized Drexel-Biddle Military Instruction Camp. The leave of absence is accompanied by full pay and will not affect the regular vacation period allowed them.

The Studebaker agency at Broad and Callowhill Streets, Philadelphia, is receiving bids for remodeling the showroom, including extensive interior decorating.

The Stevens-Duryea Motor Parts and Service Station opened on Nov. 1 at 3001 Montgomery Avenue, Philadelphia, under the proprietorship of Archie Thompson. The garage has a capacity for 100 automobiles.

The Standard Supply and Equipment Co., 1710-12 Market Street, Philadelphia, will shortly move its accessory and general equipment business to new and larger quarters at Thirteenth and Cherry Streets.

The Keystone Repair and Service Co. is preparing to erect a garage and station at 5117-19 Frankford Avenue, Philadelphia. It will be of brick, one-story high, and will cost $2,000.

The Birch Motor College, Inc., to conduct schools in motoring and engine construction, was recently incorporated with a capital of $20,000 by H. M. Brown, M. E. Shakespeare and L. S. Dorsey of Wilmington, Del.

Wisconsin News Items—The Enger Motor Sales Co., recently incorporated at Milwaukee by R. D. Mitchell and E. D. Galt to represent the Enger in the Wisconsin territory, is establishing offices and service station in the new garage building on Eleventh Street, near Grand Avenue, adjoining the Auto Mart.

The Creek Motor Sales Co., 447 Jackson Street, Milwaukee, representing the Apperson and Inter-State in Wisconsin and upper Michigan, has disposed of its agency contracts, lease on its garage and salesrooms and stock of supplies, accessories, etc., to J. C. Fowler of La-Crosse, Wis., who has taken possession.

C. A. Kinney has sold the Colfax Garage at Colfax, Wis., to a new firm organized by Charles Paul and Edward B. Rosenberg of Colfax, and styled the Paul & Rosenberg Auto Co. The company takes over the agencies for the Buick and Overland. Talvin Bronken is retained as mechanical superintendent.

P. A. Peeters of Green Bay, Wis., has organized the Peeters Welding & Cutting Co., which is remodeling the Gehr Building at Pine and Jefferson Streets for its purposes. The concern will specialize in car work but will also conduct a general machinery repair business.

The Luther Grinder Mfg. Co., 285 South Water Street, Milwaukee, manufacturing an extensive line of tool grinders and similar appliances, is now operating double turn in most departments and at full capacity in others in order to cope with the demand from car and munition factories and jobbers and retailers in farm supplies. The company operates a large 6-story plant. Although this is generally a quiet season, the business this year is far and away beyond that of any previous year.

Andreas M. Soennichsen, inventor and designer of car parts and accessories, who recently retired from the Auto Parts Mfg. Co., Milwaukee, has organized the A. M. S. Co. of Milwaukee to engage in the manufacture of a line of newly patented articles for the car trade. A plant has been established in the Manufacturers' Home Building, foot of Mason Street, Milwaukee. The company is capitalized for $10,000 and in addition to Mr. Soennichsen the incorporators are G. W. Browne and T. C. McMillan of the Overland-Wisconsin Co. and G. W. Browne, Automobiles, Inc., Milwaukee. The products will include shock absorbers, windshields, bumpers and fenders, etc.

Illinois Trade Items—James Keller, formerly of the Portage Rubber Co., Chicago, purchased the Kenny Tire Shop at the corner of Fourth and Jackson Streets, Springfield, Ill. He will handle the Miller and Portage tires in Sangamon County.

The Irwin-Overland Automobile Co., Quincy, located at 300-310 Maine Street, has completed extensive improvements which include two additional offices, one for Leaton Irwin and the other for F. R. Lusk. Another story will be added to the building later, which will be utilized for accessories. The firm has decided to embark in the wholesale tire business and will utilize the concrete basement for storage purposes. A two-story building, 190 ft. in length at 217-321 Maine Street has been leased and will be utilized as a store room for cars. Starting with a 500-car contract per annum, the firm has increased this until the contract for next year calls for 1800 cars.

B. Pinkerton, president of the Pinkerton Motor Car Co., Peoria, has leased the old plow shop in Pekin, Ill. This structure contains three stories and will be utilized as a warehouse for the storage of Ford cars and accessories, and also as a branch office for Pekin and Tazewell county trade. A service station will also be established.

Noah Henline, for several years an automobile salesman in Bloomington, Ill., being employed by T. K. Hays and later by C. U. Williams, has resigned from the latter firm to enter the office of the Dodge Bros., at Memphis, Tenn., and will have charge of the southern distribution of cars for this firm.

Baltimore Co.'s Add—The Poehlmann Automobile Co., Chevrolet distributor, Cathedral and Chase Streets, Baltimore, will open a new department for automo-

bile supplies. J. R. Manuel will have charge of the new department.

The International Motor Co. will award contract for the building of a garage at 1006-1012 North Eutaw Street. The new building will be one story, 66 by 150 ft., of brick and reinforced concrete.

Denver Men Make Changes—W. A. Murphy, who recently secured the Colorado and Wyoming distributing agency for the Detroit Package Wagon, has now opened permanent quarters at 1608 Broadway, Denver.

W. S. Dawson, recently sales manager for the Charles F. Cole Motor Co., Pathfinder distributor, now has a similar position with J. M. Patrick, 1515 Cheyenne Place, Colorado and Wyoming distributor for the Lewis, Abbott-Detroit and Kissel.

Sam Stephens, for three years Pierce salesman for Tom Botterill, Denver, has been made assistant to C. A. Biggs, recently appointed Mountain States district representative Dodge Bros., with headquarters at 1608 Broadway.

York Dealer Builds—With the incorporation of the York Auto Exchange, R. P. Anderson, manager, this week, plans were started for the erection of a $20,000 fireproof garage and salesrooms on the southwest corner of East King and Queen Streets, where the company has purchased a plot of ground 90 ft. by 60 ft. The new firm, which will trade under the name of the Anderson Auto Sales Co., is capitalized at $30,000. It will hold the agency for the Cadillac, Studebaker and Reo cars and will maintain a repair station and handle a line of accessories. The business which the York Auto Exchange now maintains at the corner of North Duke Street and Clarke Alley will be discontinued when the new garage is ready for occupancy.

Fisk to Enlarge in Boston—The Fisk Rubber Co. has bought two large parcels of real estate at Boston, Mass., on Beacon Street, one adjoining the lot upon which the Peerless, Hudson, Autocar, King and Firestone Tire buildings are erected, and the other on Deerfield Street. The first piece of property comprises 17,000 sq. ft., taxed for $123,000, and the company will have a new building erected there for general offices and salesrooms. The other property comprises 14,000 sq. ft. taxed for $56,000, and a two-story service station will be erected there. It is said that the company paid in the vicinity of $200,000 for the land. The new location is at the big junction point of Commonwealth Avenue and Beacon Street.

Denver Fisk's New Building—The Fisk Rubber Co. is breaking ground for a new building at 1200 Broadway, Denver. It will be 50 by 125 ft., one story and full basement, and will cost $25,000 to $30,000. The main feature will be a service room large enough for ten or twelve cars, which will furnish a big improvement over the recent branch headquarters at 1635 Broadway. The new building is expected to be ready for occupancy by the first of the year.

Represents Kalamazoo Spring—The Cutting, Armstrong & Smith Sales Co., Detroit, is now representing the Kalamazoo Spring & Axle Co. of Kalamazoo, Mich.

New Master Carbureter Distributor—The Master Carbureter Corp., Detroit, has appointed the Lincoln Garage, South Bend, Ind., as its distributor for South Bend and vicinity.

Commercial Body Moves Offices—The Commercial Auto Body Co., St. Louis, Mo., has moved its offices and salesroom to its factory at Sixteenth and Pine Streets, St. Louis.

Spokane Items—O. J. Goeffinger and Albrecht Gross of New York City have opened the Washington Magneto Exchange at 1017½ Sprague Avenue. Mr. Goeffinger was formerly in the automobile business in New York, while Mr. Gross was associated with the Wisconsin Magneto Co. of Milwaukee. The new concern will be agent for the Rayfield carbureter and other accessories. It will handle and repair all kinds of electrical equipment and magnetos.

F. A. Williams has taken the agency for the Republic truck, the deal having been closed with H. W. English, representative of the Republic Motor Truck Co.

St. Louis Battery Co. Moves—The Moerschell Electric and Auto Supply Co., St. Louis, is making preparations to move into its new quarters at 2944-2946 Locust Street, a new building treble the size of the present quarters of the company. This firm is the exclusive agent for Willand batteries in St. Louis, and will have a charging capacity of 600 machines a day at the new plant.

Kansas City Department Store Tire Agent—The Jones Store Co., one of the largest department stores in Kansas City, is the first department store there to put in a tire department. The store has bought the equipment and business of the Pennsylvania Tire Co. agency known as the Tire Service Co.

Seattle Items—The Matthews Motor Car Co. is the name of the new distributors of Jeffery cars in Seattle and western Washington, located at 1409 Broadway. At the head of the company is J. G. Matthews, who for thirty-five years was in the banking business in Kentucky. Associated with Mr. Matthews are Dr. S. N. Colliver, vice-president; J. W. Bailey, secretary, and J. F. Scearce, treasurer.

Swinehart Tire Sales Co., Seattle, has secured the agency for Continental and Stanweld rims.

New Incorporations

Delaware

DOVER—Smith Form-a-Truck Co.; $100,000; maker. J. F. Curtin, S. B. Howard, S. A. Anderson.

WILMINGTON—E. I. du Pont de Nemours Powder Co.; 240,000. E. N. McCarney.

Indiana

AUBURN—Union Automobil Co.; $100,000; maker. C. M. Brown, John Zimmerman, W. H. Schaab.

CHURUBUSCO—Churubusco Auto Co.; $5,000. F. Fegel, W. E. Moudy, W. S. Moudy, A. M. Hire.

FORT WAYNE—Wayne Garage Co.; $2,500. C. V. Pion, C. E. Pfeffer, E. L. Pfeffer.

JEFFERSONVILLE—Bensinger Automobile Co.; $5,000 Archie Bensinger, A. B. Bensinger, Clifford Bensinger.

Illinois

CHICAGO—Chateau Garage; $2,500. P. S. Oberweise, H. W. Leybourne, F. N. Wood.

HUBBARD WOODS—Hubbard Woods Motor Car Co.; $5,000. F. J. Haarth, Pearson and W. N. Schnedder.

PEORIA—Fitch Auto Supply; $6,000. Robert Fitch, C. Lynch, M. M. Fitch.

Michigan

ST. JOHNS—Hayes Truck Wheel Co.; $100,000; maker. C. B. Hayes.

Missouri

ST. JOSEPH—Diamond Motor Co.; $2,500 to $5,000.

North Carolina

YADKINVILLE—Seagraves Ford Transportation Co.; $5,000. W. B. Seagraves, H. B. Seagraves, J. C. Wallace.

New York City

NEW YORK CITY—Twentieth Century Garage; $60,000. T. B. Hoy, M. L. Shav, B. J. Beck.

NEW YORK CITY—Voultry Tire Co.; $10,000. J. Coldmixon, A. S. Hoffheimer, F. S. Voultry.

NEW YORK CITY—Wheeler Motor Co.; $10,000. H. A. Strallhols, C. W. Williamson, L. V. Chew.

NEW YORK CITY—Winn Taxi Service Co.; $5,000. E. J. Winn, Jacob Levine, Herman Yachnin.

NEW YORK CITY—Keyless Auto Clock Co.; $125,000. O. A. Perry, F. Phinney, E. J. Hogerty.

NEW YORK CITY—Armstrong Rubber Co.; $200,000; tire maker. G. F. Armstrong, S. X. Newman, S. Mallach, 60 St. Nicholas Avenue.

New York

HUDSON—Hudson City Crescent Garage; $50,000. O. A. Coon, H. S. Williams, W. H. Beardsley.

LARRABEE—Deyo Motor Truck Co.; $80,000. H. C. Larrabee, A. C. Crossley, A. J. Parsons.

LONG ISLAND CITY—I. S. Automobile Radiator Co. to Long Island Automobile Radiator Co.

ROCHESTER—No-Bust Tire Co.; $100,000. A. G. Small, H. L. Barner, A. M. Ferguson.

New Jersey

PATERSON—Griffin Carbureter Co.; $25,000; maker.

Ohio

AKRON—General Rubber Mfg. Co.; $200,000. M. O'Neil and others.

CLEVELAND—R. C. Hull Supply Co. to R. C. Hull Electric Co.

COLUMBUS—Twenty-first Street Auto Laundry Co.; $1,000. J. Thirston, K. T. Churston, E. C.

ELYRIA—Overland-Elyria Co.; $10,000. A. L. Jackson, C. Jackson, L. B. Fauver, R. H. Rice.

MARION—Marion Tire and Rubber Co.; $300,000. A. J. Berry, W. T. Jones, J. L. Price, W. F. Meyer, R. T. Lewis, W. H. Holvertott, S. P. Lippincott.

Pennsylvania

PITTSBURGH—S. S. V. Motor Co.; $10,000. J. H. Weeks, J. R. Zinkman, C. B. Gearing, J. F. Tyrell.

Texas

PARIS—Lamar Motor Car Co.; $7,500. Ed. Hutson, H. H. McClanahan, T. A. Johnson.

Virginia

CLIFTON FORGE—Virginia Garage Co.; $30,000. B. H. Tatum, E. A. Snead, B. C. Goodman.

RICHMOND—King & Wright Co.; $15,000; buying and selling engines. H. D. Wright, H. R. Scott, A. G. Collins.

VOL. XXXIII. NEW YORK—THURSDAY, NOVEMBER 18, 1915—CHICAGO NO. 21

The AUTOMOBILE

Steering Gears Offer Many Problems

Actual Gear Superior to Layout—Lubrication the Great Trouble—Better Protection Desirable —Great Opportunity for Clever Detail Design

By A. Ludlow Clayden

STEERING gear as a matter of design has two sides, the mathematical and the mechanical. In THE AUTOMOBILE for Sept. 2, the former aspect of the subject was dealt with, it remains to review the other side and to study the detail of steering gears and connections. Steering is an automobile quality which is prone to deteriorate by the development of lost motion or slack between the hand wheel and the road wheel and this is due to two causes, the first being the number of bearings in the linkage, and the second the difficulty of properly lubricating those bearings.

Usually wear takes place first on the pin or yoke joints at either end of the tie rod, second on the universal joints of the drag link, third in the gear itself, and fourth in the axle swivels, though three and four may often be reversed in order. Wear in the actual steering gear is not so very troublesome, because there is frequently some means of taking up slack, also the opportunities for lubrication are ample so that undue wear in the gear generally means neglect on the part of the owner. All other parts, however, are difficult to deal with because the movement is so slight.

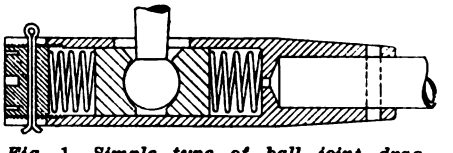

Fig. 1—Simple type of ball joint drag link connection for steering gear

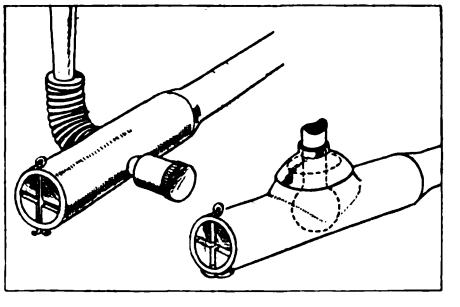

Fig. 2—Left—Suggested type of joint with a short piece of flexible metallic tubing for holding grease or oil

Fig. 3—Right—Suggested type of self-protecting, oil-retaining universal joint

For the great majority of steering movements the wheel is not deflected more than a very few degrees back and forth, and this slight motion is of little value in distributing lubricant. Where grease is used, the lubricant is forced in by hand in screwing down the cup, and it then squeezes out of the loaded part slowly, staying out till such time as a fresh supply is injected. Oil would be able to find its way around the whole surface, but is apt in most cases to escape altogether, leaving the joints even more dry than where grease is employed.

Greasing up two tie rod joints, two swivels, two drag link connections and one steering gear case is an operation taking time and much crawling about on the ground; while it is utterly impossible of accomplishment without donning overalls or ruining clothes. There used to be plenty of such dirty jobs on a chassis, but one by one they have been abolished, leaving only the steering gear practically in the same state as it was fifteen years ago.

The only way out of the difficulty that appears, is to make the joints self-lubricating so that they require attention at long intervals only. Also a great help would be to increase the size of the parts and so decrease the pressures. Yet another aid to durability, which is not exploited as much as it ought to be, is to use non-rusting metals wherever possible; to put in bronze bushings for the pins and to make joints which will be as nearly as possible waterproof. Leather boots or wrappings are a palliative only, however well made they may be, their life is fairly short and they are distinctly *not* engineering.

It is a wonderful thing, an amazing thing, that of all the automobile engineers in the world not twenty have produced cars that steer really well, and continue to do so month after month with little attention.

Taking the drag link connections first, these may be either ball joints or regular little universal joints. The former type is most used because it is cheaper and just as satisfac-

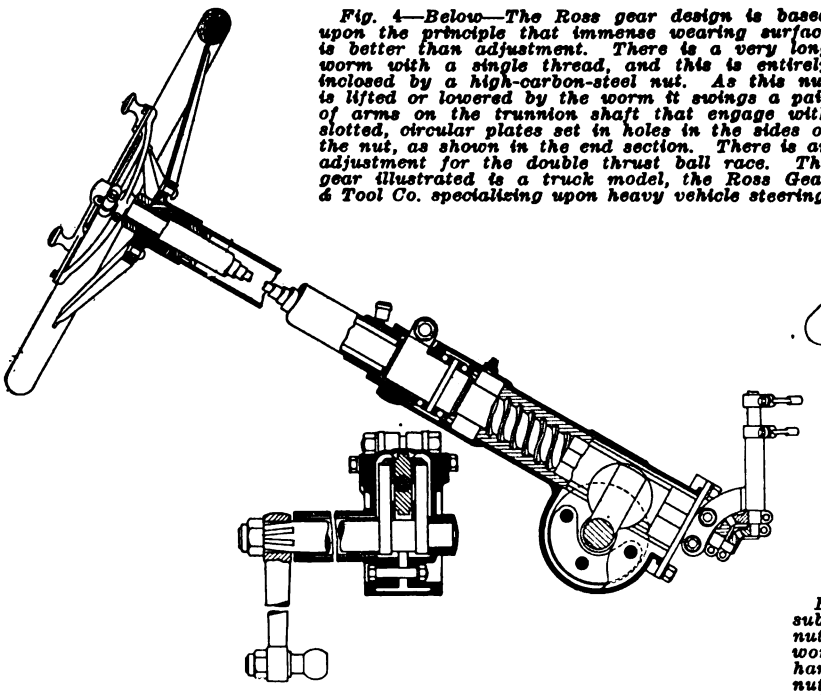

Fig. 4—Below—The Ross gear design is based upon the principle that immense wearing surface is better than adjustment. There is a very long worm with a single thread, and this is entirely inclosed by a high-carbon-steel nut. As this nut is lifted or lowered by the worm it swings a pair of arms on the trunnion shaft that engage with slotted, circular plates set in holes in the sides of the nut, as shown in the end section. There is an adjustment for the double thrust ball race. The gear illustrated is a truck model, the Ross Gear & Tool Co. specializing upon heavy vehicle steering

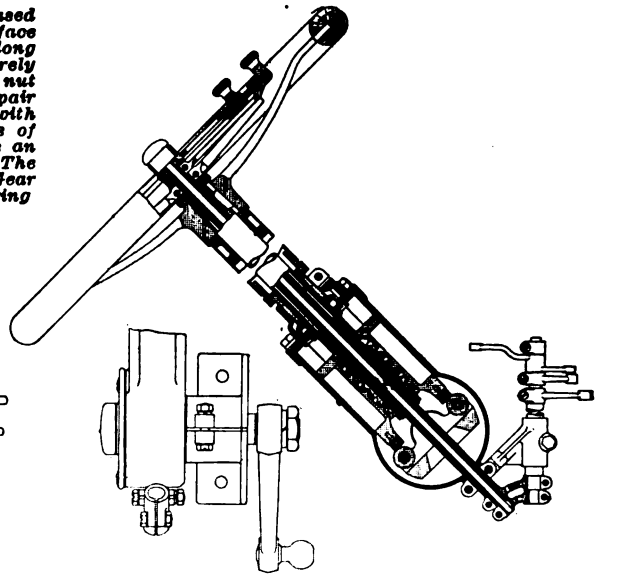

Fig. 5—Above—The Jacox steering gear has a substantial steel worm inclosed by a semi-steel nut, which is split lengthways into halves. The worm is double threaded, both right and left hand, so that turning the wheel causes one half nut to rise while the other falls. The ends of the nuts bear upon a rocking yoke which is connected to the external steering arm. One of the greatest virtues of this design is that a single adjustment of the nut that backs the ball thrust race takes up all wear. Owing to the very large thread surface wear is very slow. The maker is the Jackson-Church-Wilcox Co.

tory as the latter if made properly. There have been a good many accidents due to ball joints dropping off, and many ways for preventing this have been devised. One of the simplest is shown in Fig. 1. This is not any particular joint, but is the basic principle of several. The main idea is that the cups whch press against the ball are backed by strong springs that take up the wear automatically, and if one spring breaks the other drives the whole assembly along till the neck of the ball is caught by the edge of the hole in the outer case. The only drawback to this style of joint is the difficulty of renewing lubricant, for to get grease actually between the ball and the cup it will not suffice to plaster the outside. To make certain of it the joint needs to be taken apart and greased in that condition. Mud, and washing water from a hose also tend to remove the lubricant rapidly.

It is not easy to see how this type of joint could be entirely inclosed, but Figs. 2 and 3 show a couple of rather clumsy suggestions. The former uses a short piece of flexible metallic tube which would hold a soft grade of grease and possibly a heavy oil. The latter adapts the idea of the self-protecting universal joint and would be *oil* retaining. These devices should greatly outlast leather wrappings which are never completely waterproof and cannot hold oil.

Some Special Joints

A rather ingenious joint used by a few automobile makers is shown in Fig. 6; this is non-adjustable but it is to a great degree self-protecting. The grease being fed to the interior of the ball insures it reaching the working surface, and in exuding it drives all dirt before it. Such joints will wear for years if the greaser is given a turn every day, but their life depends upon this attention.

On the Peugeot racing cars there are no ball joints, the little universal shown in Fig. 9 being used instead. With this type grease can be supplied through hollow bolts as for a spring shackle bolt, and frequent attention to the grease cups will prevent wear. The universal type of connection is less easy to inclose, however, and when exposed is just as great a sufferer from neglect as the ball joint, which is simpler and cheaper.

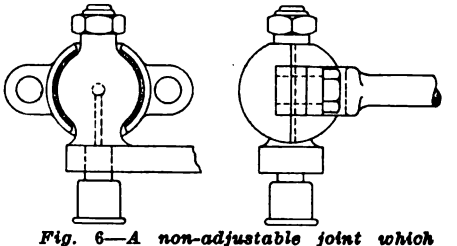

Fig. 6—A non-adjustable joint which is, however, to a great degree self-protecting

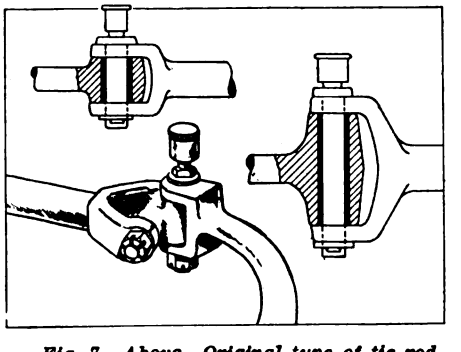

Fig. 7—Above—Original type of tie rod yoke. Fig. 8—Right—Illustrating how durability of this type has been increased by widening the jaws. Fig. 9—Small universal used instead of ball joints on Peugeot racing cars

Tie Rod Joints Get Longer

The original tie rod yoke was something like Fig. 7, and the durability of this bearing has been increased greatly by widening the jaws so as to give more surface to the pin as in Fig. 8. Wear on these joints is particularly annoying because it not only gives slack to the steering wheel, but it is liable to set up a continuous rattle of most irritating character. Here again lubrication is rendered difficult by reason of the extremely small angular movement and the only solution of the difficulty is frequent application of fresh oil or grease. The self-lubricating bushing of compressed graphite ought to find an application here and there is no reason save cost why the pins should not be bronze instead of steel.

Some manufacturers of expensive cars have used ball joints for the tie rod instead of ordinary yoke ends and where there are self-adjusting springs this prevents rattle. Probably the greater difficulty of protecting and lubricating the ball joint offsets the main advantage, however.

Schemes for Swivel Lubrication

There are two types of front axle, the most popular in America being that sketched in Fig. 13, and the one most used in Europe in Fig. 14. The difference is that in the American pattern the thrust bearing is located at the upper end of the swivel pin, while in the other variety it is at the bottom. Taking the most used type, the tendency is for the pin to wear at the ends, and for the

thrust washer to wear. From the viewpoint of freedom in steering it is an advantage to use a ball thrust bearing, but there are two drawbacks, first water, if it enters as it practically must do sooner or later, will destroy the balls and races immediately; second, the movement is normally so slight that the balls tend to make pits in the races due to repeated shocks. Thus the plain thrust is better if only it can be lubricated. Obviously, a plain thrust bearing with an area of 2 sq. in. or so and with a load of 1000 lb. on it is not easy to grease, and the grooves cut in the face of the washers do not help much as there is so little movement to distribute the grease.

It has often been an ideal with designers so to arrange the thrust bearing that it is permanently in a bath of lubricant. In Fig. 15 the Sunbeam design is shown and it may be noticed that the big brass cap at the top entirely protects the ball thrust washer from water, which could not reach it by any possibility. Also it is only necessary to remove the cap and fill it with grease about as frequently as it is necessary to do the same by hub caps, if indeed as often. This example is chosen as being one of the first attempts, but the same idea appears in various forms in a good many modern designs. Excellent steering swivels have been made with all ball bearings, both of journal type and cup and cone type. Also swivels have been made with taper roller bearings, but the plain bearing for the pin, combined with a properly lubricated thrust, also plain, gives just as good an effect as the expensive combinations.

Probably the reason that the detail of steering gear has had so little attention is that the cheapest forms will operate fairly well if they get a complete overhaul every 10,000 miles or so. For a really cheap car this is good enough, but the buyer of an expensive machine is quite capable of appreciating a design which would reduce the trouble of greasing and enable the steering to be maintained in its original state of efficiency for the life of the car without rebushing joints. For the manufacturer who wants a novel talking point that of safe, easy and durable steering offers a hitherto neglected opportunity.

Steering Gears of Many Patterns

For the passenger car an absolutely irreversible steering mechanism is not desirable, for it destroys the "feel" which is essential to quick steering and is obtained by a gear that is just a little short of being quite irreversible. It is necessary to strike the happy mean.

In the main, steering gears divide into two types, those with a short worm and worm wheel, or part of a wheel, and those with a screw and nut. The former is the simpler, but it is less easy to adjust for wear and it does not give so large a wearing surface. In early attempts with the screw and

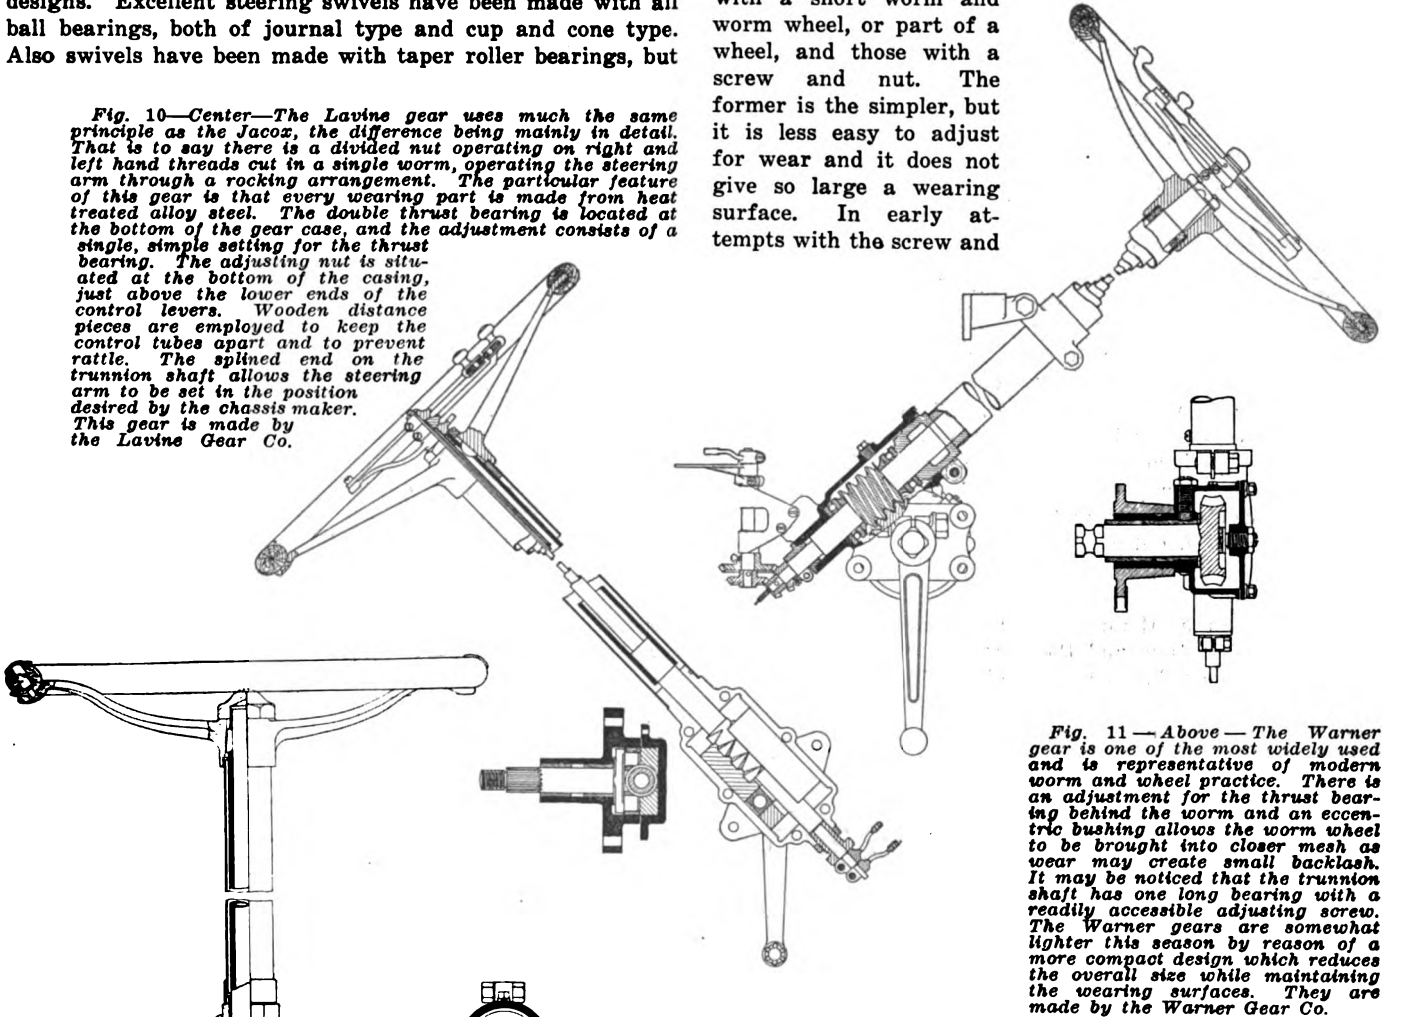

Fig. 10—Center—The Lavine gear uses much the same principle as the Jacox, the difference being mainly in detail. That is to say there is a divided nut operating on right and left hand threads cut in a single worm, operating the steering arm through a rocking arrangement. The particular feature of this gear is that every wearing part is made from heat treated alloy steel. The double thrust bearing is located at the bottom of the gear case, and the adjustment consists of a single, simple setting for the thrust bearing. The adjusting nut is situated at the bottom of the casing, just above the lower ends of the control levers. Wooden distance pieces are employed to keep the control tubes apart and to prevent rattle. The splined end on the trunnion shaft allows the steering arm to be set in the position desired by the chassis maker. This gear is made by the Lavine Gear Co.

Fig. 11 — Above — The Warner gear is one of the most widely used and is representative of modern worm and wheel practice. There is an adjustment for the thrust bearing behind the worm and an eccentric bushing allows the worm wheel to be brought into closer mesh as wear may create small backlash. It may be noticed that the trunnion shaft has one long bearing with a readily accessible adjusting screw. The Warner gears are somewhat lighter this season by reason of a more compact design which reduces the overall size while maintaining the wearing surfaces. They are made by the Warner Gear Co.

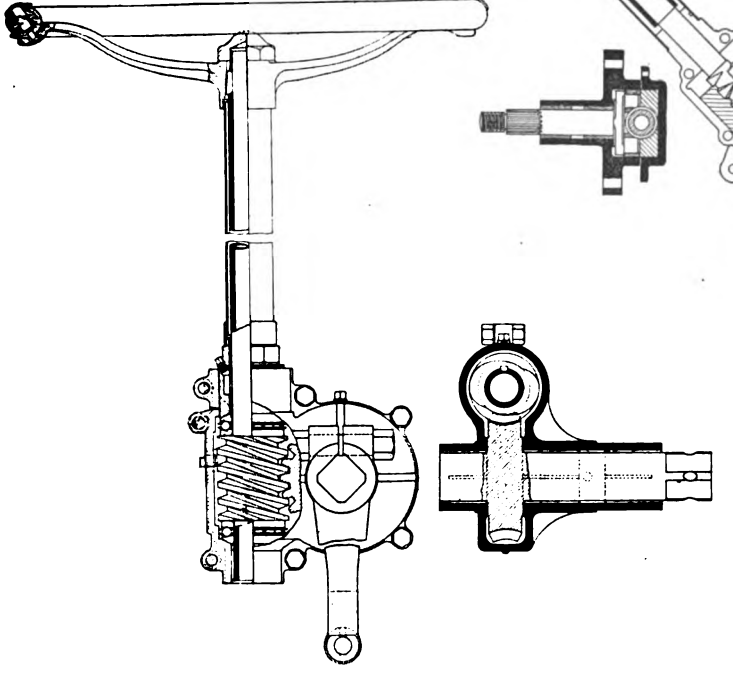

Fig. 12—Left—The Barnes gear is a worm and wheel pattern having two adjustments, one back of the thrust bearing and the other on the trunnion shaft bearings, the shaft being held in eccentric bushings. The use of a full worm wheel and a square end shaft allows the four quarters of the worm wheel to be used in turn, thus providing yet another increase of durability. This gear is made by the Barnes Gear Co.

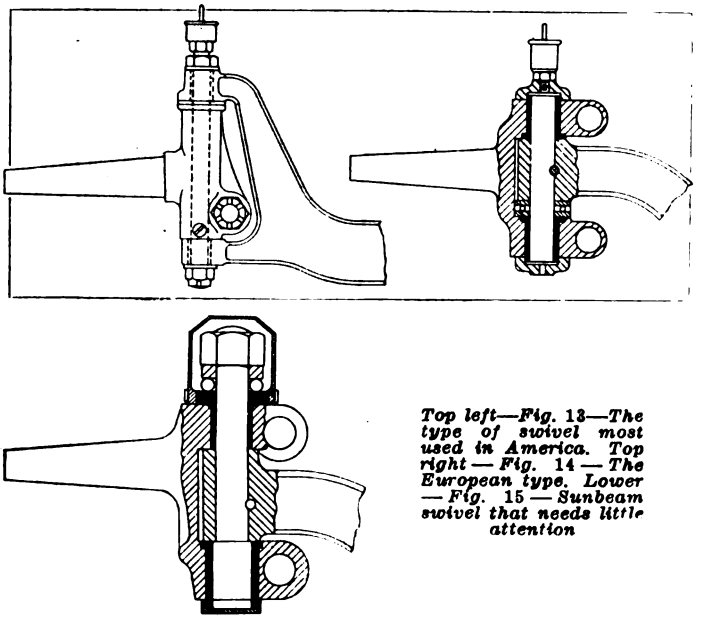


Top left—Fig. 13—The type of swivel most used in America. Top right — Fig. 14 — The European type. Lower — Fig. 15 — Sunbeam swivel that needs little attention

nut type the advantage of big contact on the thread was often lost by the use of some sort of rocking joint which had a very small surface, but this has been corrected, and to-day there are plenty of nut gears possessing remarkable durability.

Simplicity favors the worm and wheel type, and if this is well made with a good size of thread its durability is excellent. Practically the only adjustment possible is to mount the worm wheel on eccentric bushings, so that it can be brought into closer contact with the worm as it wears, but this adjustment is imperfect, because wear is never even, since it nearly all occurs at the center position corresponding to a few degrees of steering movement only. The idea of using a complete worm wheel instead of a segment is that when one quarter of it has worn, the wheel can be removed from its shaft, given a quarter turn, and replaced with a fresh, unused surface to the worm. If the worm is the harder member of the gear this practically quadruples the life of the gear. A nut gear can be adjusted in several ways, and needs an adjustment for the rocker bearing as well as for the nut.

In the design of these gears there has been only detail change for some time and they are mostly of a quality of service that precludes the probability of alteration. Here and there weight has been reduced by simplification of design and by the use of materials with a greater strength.

In general, the aim of the maker of the gear is to provide the largest bearing surfaces possible with reasonable weight and size so that adjustment shall be necessary only at very long intervals. There are, of course, very many different patterns of steering gears, but in selecting the few which are illustrated in section it has been attempted to cover the main princples in common use.

Adjustable Rake

A feature of steering gear construction which is obtaining greater attention is the inclusion of some device whereby the rake of the column or post can be altered. Ability to so set the angle is very useful to the automobile manufacturer who usually is well cared for by the steering gear specialist. It is to be regretted that the automobile maker so rarely constructs the body and the clamping arrangements for the gear that the user is able to swing the gear an inch or two forward or back to suit his stature.

In mounting the different parts of the gear, ball bearings are almost always employed for taking the thrust of the worm or screw, except in gears which are subjected to very violent shocks, as are heavy truck steerings. For journal bearings there is a marked trend toward the ingenious self-lubricating bronze bushings with graphite inserts. With such equipment only an extremely small quantity of oil has to be inserted to keep the worm thread in good condition; the bearings look after themselves.

Another point which has caused trouble in the past, but has now been overcome is that of rattle between the several tubes inside the post, which connect with the control levers above the steering wheel. Where there are three or four drawn steel tubes of this section one inside the other, vibration can readily set up a chatter that is particularly irritating. All gear makers almost have settled upon one way to prevent this chatter, that of giving the tubes bearings on each other at sufficiently short spacing. Sometimes this is done by knurling the tubes or raising collars on them, sometimes by the insertion of bronze bushings and sometimes by wooden spacers. All seem equally effective in service.

Materials Are Factors

Materials used in construction do not vary very much, the important wearing parts such as the worm and guides or rocker pinions being a high quality steel. For the outer case malleable cast iron is most popular, and the tubing is commonly cold drawn steel. Choosing steel for steering parts is a somewhat delicate operation, because surface hardness to give durability is needed combined with great toughness to resist the continual shocks to which a gear is subject, hence steels of the nickel chrome variety and alloy steels deriving their qualities from careful heat treatment are used frequently.

Packard Uses Special Vehicle for Moving Machinery

Building operations at the plant of the Packard Motor Car Co., Detroit, Mich., are going forward at such a rapid rate that it has been found necessary to construct a special vehicle for the transportation of machinery between the old and new factory units. As shown in the accompanying illustration, where a special crankcase milling machine weighing over 21 tons is being moved by a Packard 4-ton truck, the special vehicle is constructed of extra large motor truck wheels, mounted on special axles and carrying a platform made of 12-in. channel steel frame and special oak flooring. At the forward end of this float is anchored a winch by which the machinery is loaded onto its truck

Gearsets Are Smaller and Lighter

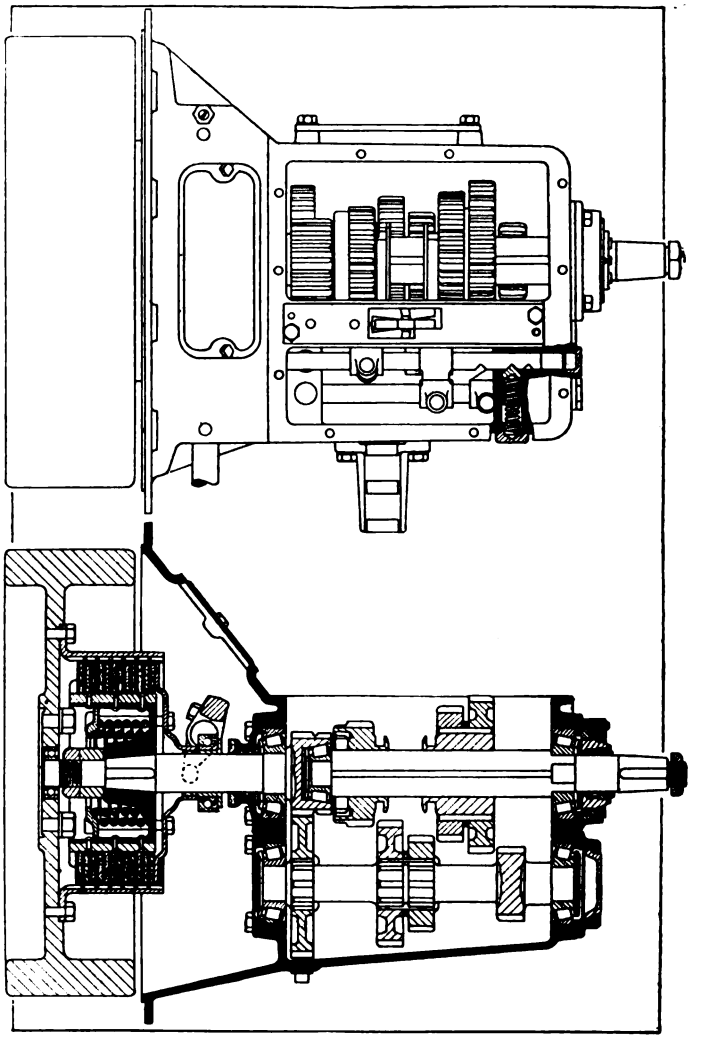
Roller Bearings Increasing in Favor—Popularity of Iron Case Due to Noise Problem—Ease of Gearshifting Obtained by Clutch Design

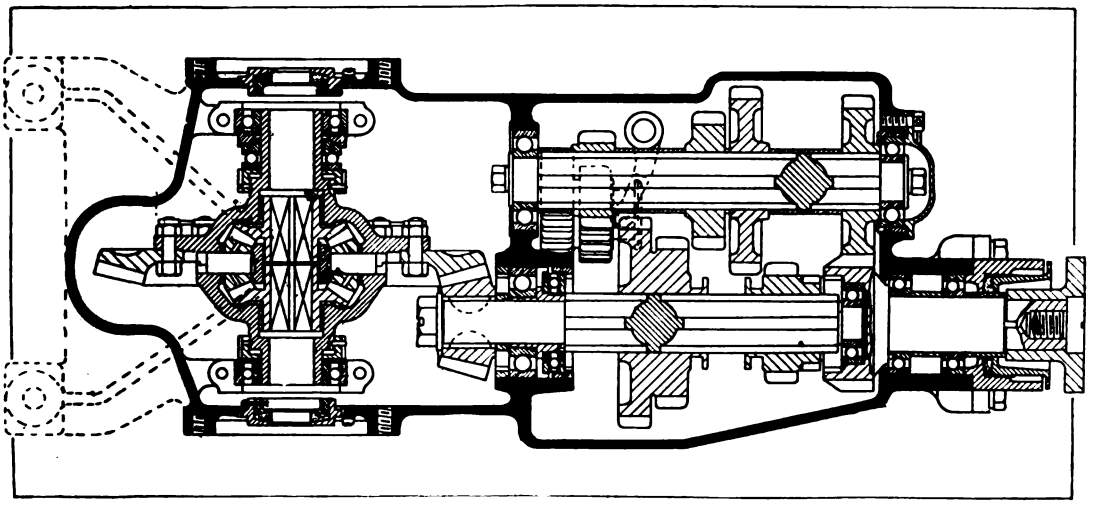
AS with steering gears, so with gearsets, change has been slow and development by easy stages. There has been only one great change in automobile gearboxes since they first were used, this being the introduction of the direct drive, which came more or less simultaneously with the live axle transmission. From this point onward development has been directed toward simplification of detail, elimination of noise and reduction of size and weight.

Lately the main development has been the great simplification rendered possible by the coming of center control, and changes in the form of bearings most popular with manufacturers can also be observed. Steady abandonment of the rear axle situation for the gearset and the growth in favor of the unit power plant has made noise in the gearing far more difficult to eliminate, or rather, more noise is permissible in the old type than can be allowed for the new. Of course, in these days of everywhere on high, the noise made by second speed and low gears is of little importance, that which counts is the hum of the constant mesh pinions. It is the opinion of several prominent engineers that the most potent influence in reducing this sound is continuity of engine torque, eights and twelves proving easier to cope with than sixes or fours, but apart from this the bearings used seem to have the greatest influence. That the quietest gearset is obtained by the use of all plain bearings seems to be agreed by everyone, but the difficulty of satisfactory lubrication is such that ball or roller bearings are used almost always for both portions of the main shaft.

For the countershaft plain bearings are used fairly often, because the latter can be so situated that it is in a permanent bath of oil or grease. Roller bearings especially certain types, seem to give quietness results nearly as good as plain bushings, so it is not surprising to find that their use is increasing. Of all bearings the most difficult to quieten is the ball bearing, which is regrettable, because it is the easiest to apply in limited space and its frictional efficiency is, of course, very high.

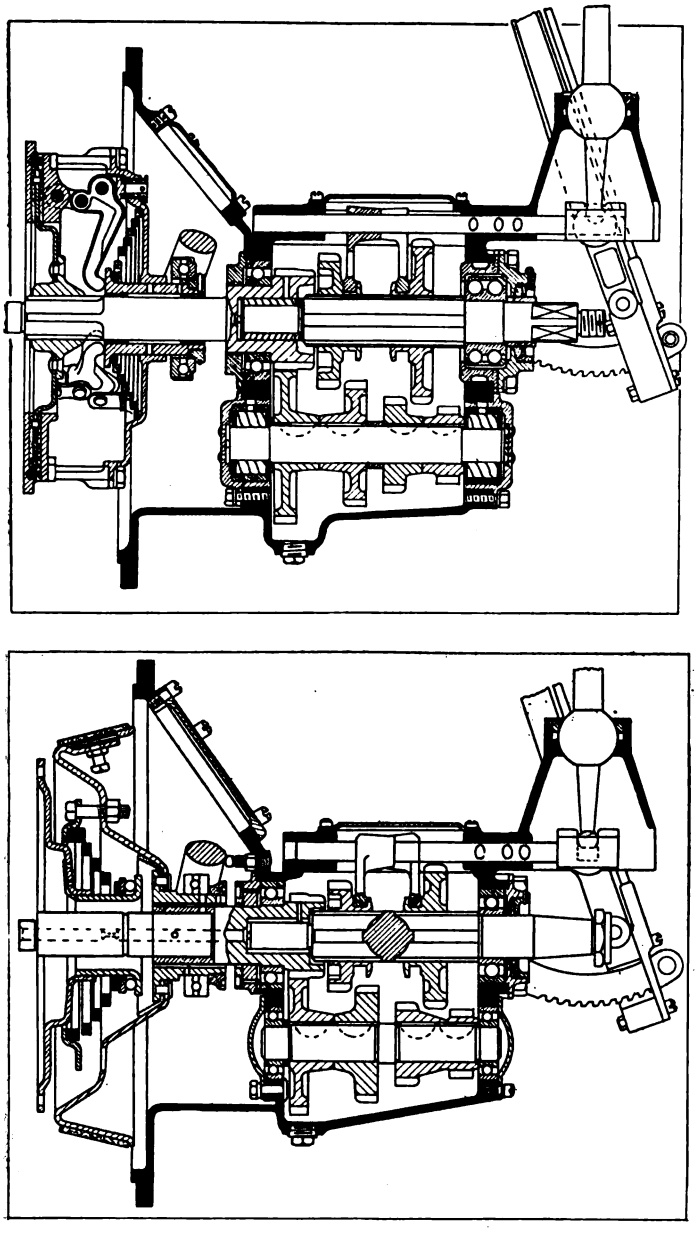
The average gearset, judged from the specifications of a



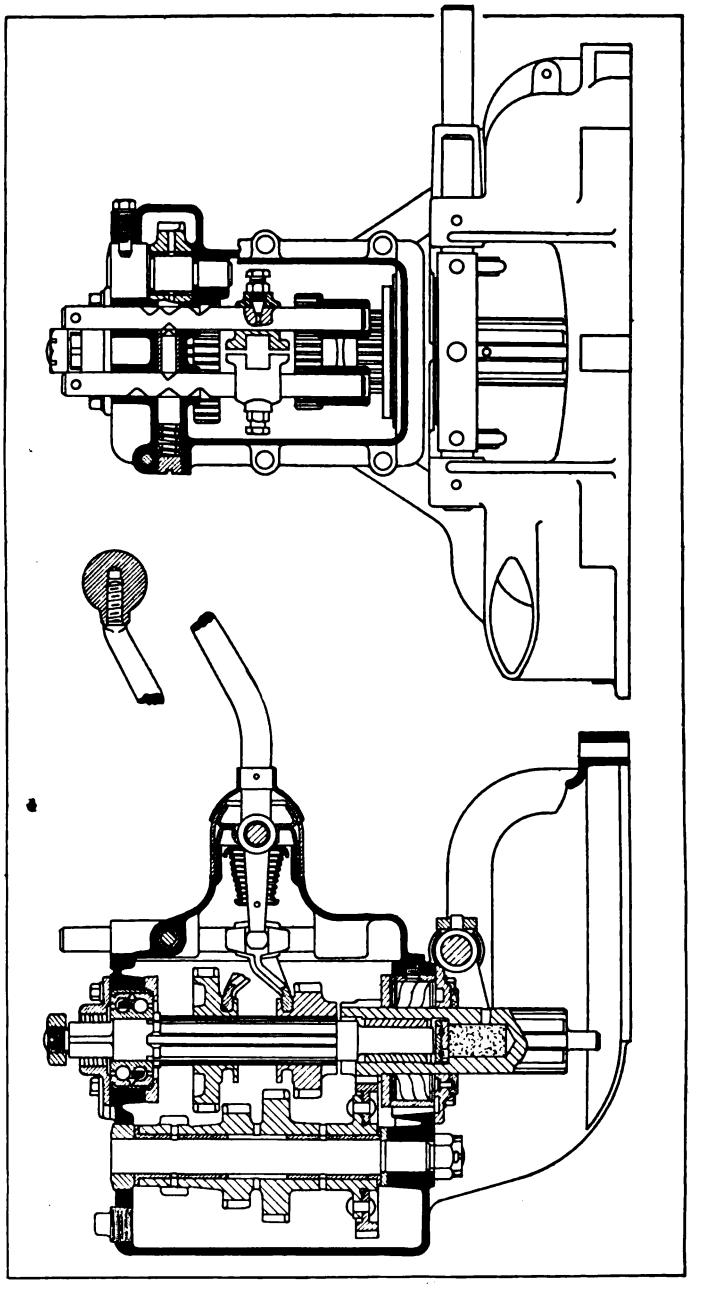


Above — Brown-Lipe four-speed gearset with several characteristic features. Special attention should be given to the mounting of the taper roller bearings and the use of one of these for the spigot. The box is small for a four speed type

Left—A Warner gearset for 3-ton trucks having chain drive. This illustrates a way of using ball bearings exclusively. Nickel-chrome steel is used for the gears to allow of sufficient strength with small dimensions



These two Warner gearsets illustrate above a moderately heavy gear and below a lighter type. The former has a large ball thrust bearing and the roller spigot that is becoming very widely used. It will be noticed that both gearsets have shafts with four splines and that the countershaft gears are separate pieces pressed on the shaft. Two types of clutch are shown and it is a Warner feature that these are interchangeable without any alteration to gearset or flywheel where the size of the gearset is the same. Both the clutches illustrated have very light inner parts.



The Northway gearset uses a stationary countershaft, the gears thereon being bushed. The front end of the main shaft relies largely upon the steady bearing in the flywheel and on the very long roller spigot. Thrust is cared for by the ball bearing at the tail end. In the plan view the interlocking device is shown. The spring support for the shift lever inclosure is a feature

large number of standard types, has ball bearings for the main shaft and roller bearings for the countershaft. Often ball bearings are used for only the front end of the main shaft, but in many cases a ball race is used at the tail end because of its ability to resist the occasional end thrust from the drive shaft.

A conspicuous bearing development is the steady increase in the number of gearsets with a ball or roller spigot bearing. This spigot has always been the weakest point in the direct drive type of transmission, because the bushing is so located that its lubrication is a trifle uncertain, and it runs at quite high speed when the low gear is in use. The load on it may also be considerable, and if it wears and so gets slack the shafts are put out of line and noise results immediately. At present the most popular bearing for the spigot is a small, special type of roller, and this has proved wonderfully satisfactory in service. A ball bearing is used in a good many gearsets but is not so easy to accommodate as the roller.

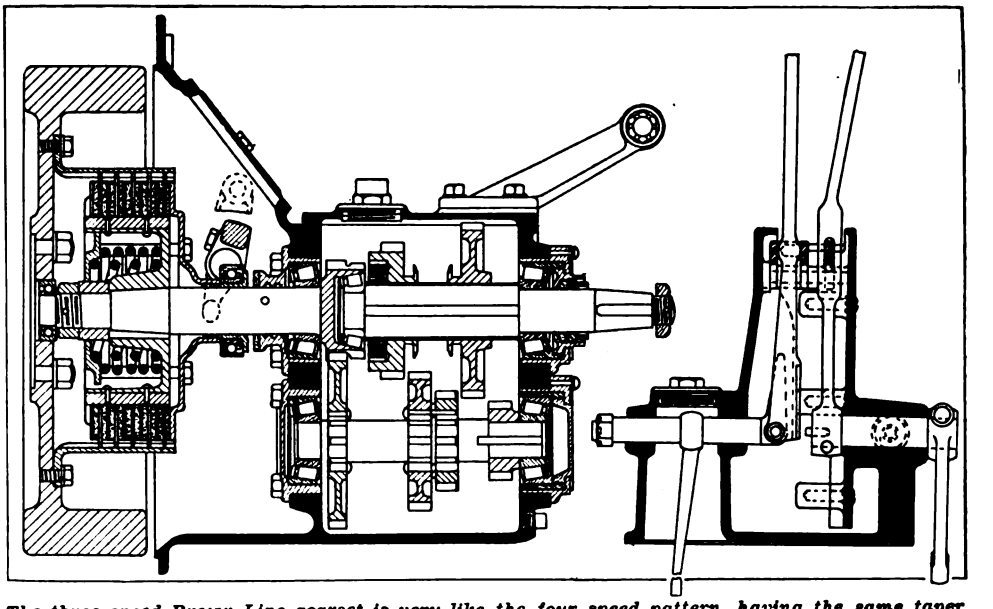
In passing, the comment may be made that it is rather remarkable the general adoption of the unit power plant has not led to the use of plain bearings throughout the gearset, with pressure lubrication from the same oil pump as supplies the engine. It would be easily possible to work out a design which would be both cheap and efficient and the need for quietness would be served in the best possible way. However, to arrange this would need a correspondence in design between motor and transmission and would hardly be applicable in a general way.

Rather curiously, many experiments with helical gears for the constant mesh pair have not led to the general use of this type of tooth; it seems no easier to insure quietness with it than with plain spur teeth. If this really is true, then it seems unnecessary to use helical teeth for the timing gears in the motor. The two cases are contradictory and the situation not easy to understand, for cost hardly enters into the matter.

An undoubtedly important factor is the rigidity of the support given to the short, front portion of the main shaft

which, in many unit powerplant designs often becomes almost an integral portion of the crankshaft when the clutch is engaged. Study of the illustrations shows how different manufacturers have tackled the problem.

Another factor in noise production is the material of which the case is made. Iron it is found, makes a quieter casing than aluminum, which at first seems curious, as iron is certainly a far more resonant metal. Probably the explanation is to be found, at least partly, in the greater rigidity of iron. While it is easier to get a quiet transmission with iron inclosure, it is quite possible to get as good results with aluminum by a careful study of the sections, and, perhaps the addition of a web or rib here and there. Just at present the price of aluminum encourages the use of iron, but it is unlikely that this will continue as the price returns to normal.



The three speed Brown-Lipe gearset is very like the four speed pattern, having the same taper roller bearings. It will be seen that the sliding shaft is of square section. The use of a double clutch spring is characteristic of Brown-Lipe practice

Most important of all, from the noise viewpoint, is the original cause of the noise, the gear itself, and it is noteworthy that manufacturers are steadily year by year, making better gears and mounting them more accurately. The allowable tolerance on the accuracy of alignment between the shafts has been made smaller, the methods for heat treating and hardening the gears have been improved, the machines for cutting the teeth are doing more accurate work. One of the leading gearset makers actually uses a burnishing process after the gears are otherwise finished, so as to remove the least roughness from the tooth faces.

Four Speeds Not Wanted

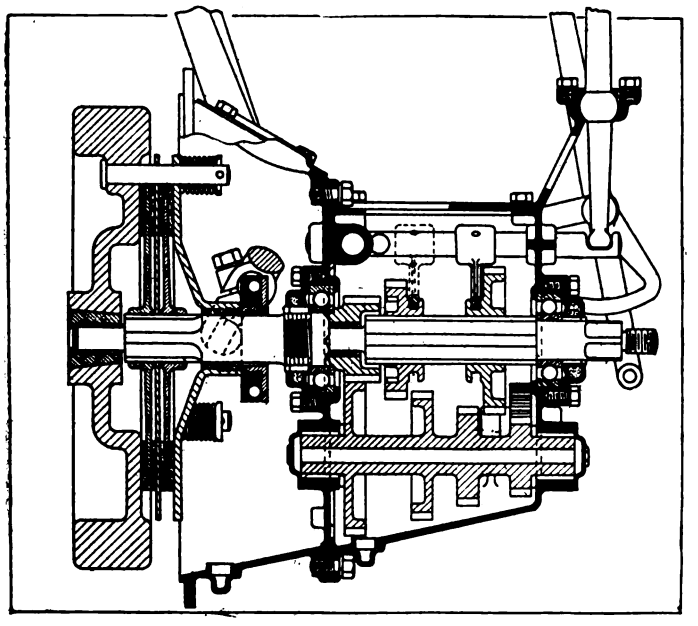
For passenger cars the four-speed gearset has almost ceased to exist, but it is still obtainable from most manufacturers, and it is stated that there appears to be a tendency toward its use for light trucks. With modern engines and the low rear axle ratios of to-day there is little need for more than three speeds in the gearset and to provide four calls for higher cost, greater weight and increased opportunity for noise. It is to be doubted whether the four-speed gear will ever return to favor; more likely is it that some totally new form of transmission will replace the gearset altogether.

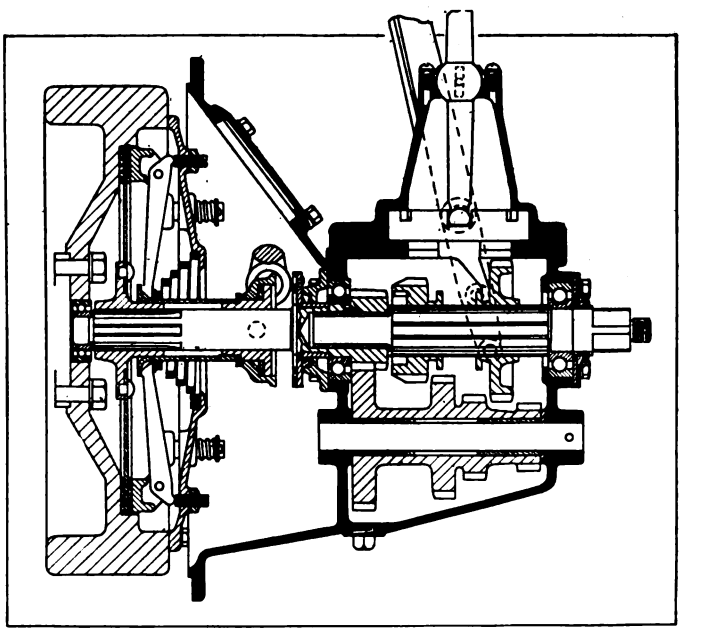
Weight Decreasing

Weight has been cut conspicuously for 1916, but this has not been done by alterations in gearset design so much as by the changes in motors. The general decrease in dimensions and increase in crankshaft speed has lowered the tooth pressures very greatly, so a far smaller gear is amply strong. At 2000 r.p.m. 40 hp. can be transmitted by a gear with half the tooth strength needed to transmit 40 hp. at 1000 r.p.m.

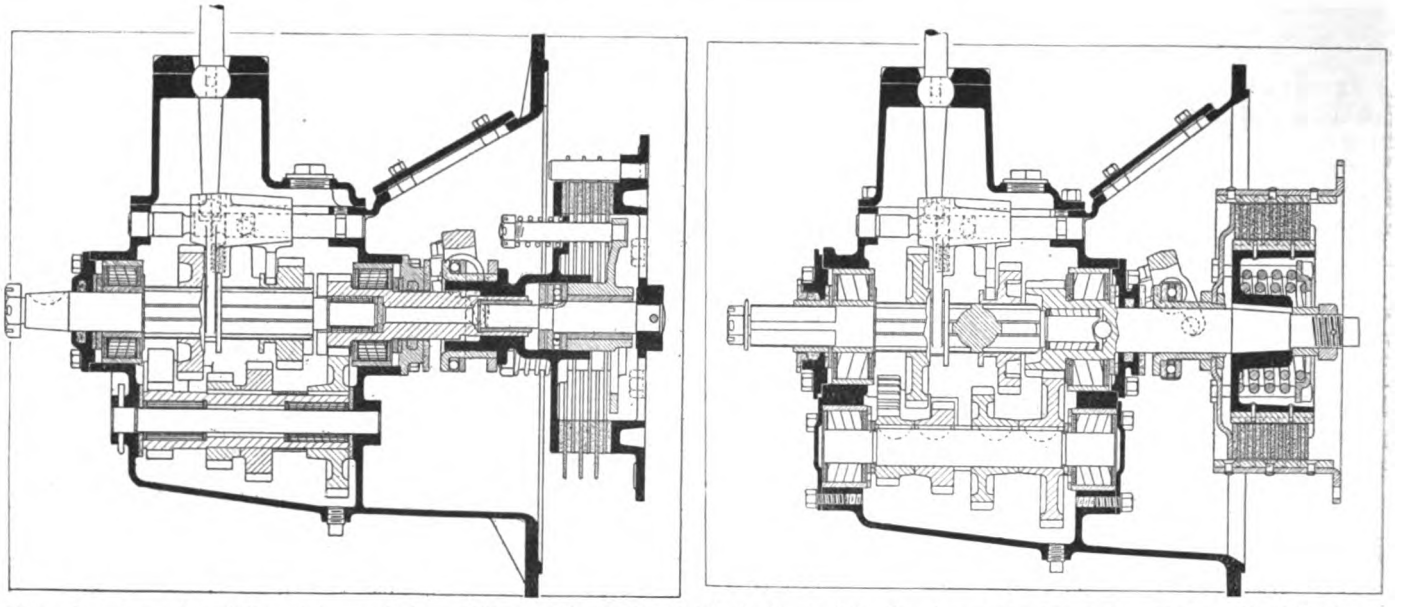
In the gearsets odd half pounds have been cut by simplification, notably in the lever mounting, and center control is, of course, lighter than any other system.

It is unquestionable that the ease of gearshifting is very





Left—A simple design made by the American Die & Tool Co. Features are the special clutch with a two-disk inner member of very light weight, and the hollow countershaft. Another point of ingenuity is the method for mounting the shift lever and its engagement with the extreme ends of the striker shafts. Right—Another simple gearset made by the Mechanics Machine Co. which also has a light clutch, this time with a single plate. The countershaft is pinned to the case and the gears bushed, while the sliding shaft has a larger number of splines than usual



These two examples of Covert transmissions differ mainly in the clutch design and in the size of the bearings. That on the left has a stationary countershaft and long roller bearings while the other has the heavy duty type of bearing and a revolving countershaft. Note how a steel ball inside the spigot is used to take accidental thrusts from the propeller shaft on the gearset shown on the right

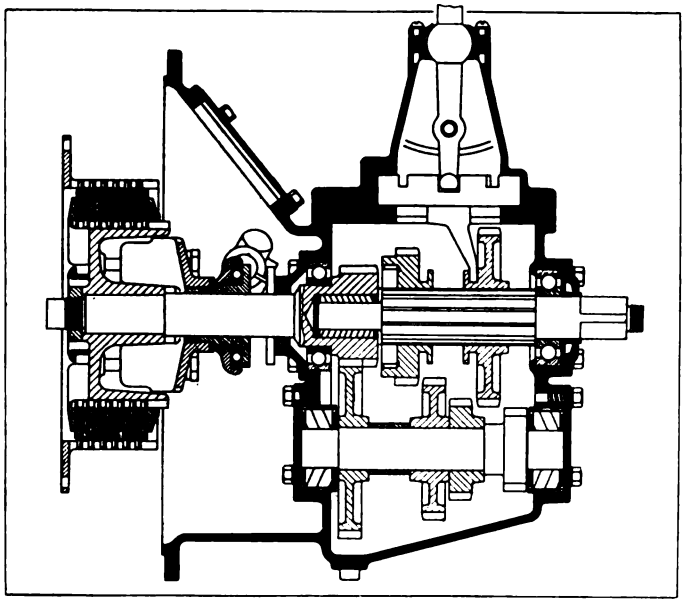
much greater on certain cars than on the average, and almost always it is found that the cars with the easy shift have very light clutch parts. There are some clutches which are so light that it is hardly possible to make a sound in shifting gears however ill judged the time for changing may have been; but the majority need some practice before proficiency is obtained.

Center Control Aids Gearshifting

Center control, and the unit power plant, which two things cut down to the minimum the number of connections between the shift lever and the gears to be shifted, have made the actual lever movement very light and easy on practically all gearsets, but there is still room for improvement in clutches. Where the increasingly popular dry disk type is used it is possible to arrange the inner member to be of extremely light weight and gearshifting becomes correspondingly easy. A very light clutch needs no clutch stop or brake and with it changing either up or down is equally easy.

With a cone clutch the same lightness cannot be obtained, but the weight can be fairly low and the provision of a good brake makes shifting upward as easy as with a lighter clutch. Where the cone clutch fails is in making a quick shift from high to intermediate, for it cannot be speeded up without a double pedal action which very few drivers ever learn to perform. Of course, there are advantages with the cone clutch, notably simplicity, ease of renewing the wearing surface, and facility of spring adjustment. The best of all clutches *when in perfect condition* is the multiple disk running in oil, but it is costly to make and difficult to keep in good condition. The nature of the oil is a trouble, cold weather is liable to cause sticking and the average repairman is not very clever with the type. Hence its use is confined almost to very high-priced constructions where efficiency is insured by an expensive design.

Dry disk and cone still just about hold their relative positions of equality, habit probably accounting largely for the continuance of the cone, and the manufacturer's natural dislike for giving up a thing which has caused him no trouble in the past.



This is a slightly heavier pattern of Mechanics Machine Co. gearset to that illustrated on the preceding page. Larger bearings of heavy type are employed and a roller spigot instead of the plain bush

No Ratio Formula Exists

Among gearset makers there is some difference of opinion as to the proper proportion of second speed to high, and low to second. Some consider that the intermediate ought to be fairly close in ratio to the high, arguing that a car will do nearly everything on these two gears and that the ease of shifting produced by a small drop in ratio encourages the driver to utilize his engine to best advantage. Others take the intermediate as the geometric mean between high and low, yet others leave the matter to the chassis designer and make ratios to suit their customers' ideas. There is no rule or formula, considering the power and weight of the car, which is used generally in determination of gearset ratios, a rather remarkable state of affairs which suggests a useful subject for some investigator to tackle as subject for an S. A. E. discussion. Theoretical ideas seem to be applied in very few cases and the discovery of some good empirical rules ought to be useful.

In conclusion, it may be remarked that the automatic gearshift, whether controlled by springs or by electricity seems to have made no progress whatever during the last year. The electric gearshift has undoubtedly been developed to a state of considerable efficiency, yet no automobile manufacturer has considered it worth its cost as a selling adjunct. This is not in accordance with the expectations of a year ago so we must await the 1916 season for possible developments along this line. They may or may not transpire.

Aluminum Discussion Evokes Enthusiasm

J. E. Diamond's Paper Stirs Detroit Engineers to Appreciation of Alloy Pistons—Future of Aluminum Production Explained by President of Aluminum Company of America

DETROIT was filled with the word aluminum on Nov. 12 for there was quite a gathering in the city of men whose names stand for aluminum in raw and finished states. They had come to hear J. E. Diamond's paper on aluminum pistons, to see what engineers thought of the latest way of employing the useful metal.

Firstly, there was A. V. Davis, president of the Aluminum Co. of America who, after the reading of the paper, held the close attention of the crowded hall while he explained how the price of aluminum came to be where it now stands, and gave a ray of hope for the future. Then E. E. Allyne and W. P. King, president and vice-president of the Aluminum Castings Co., and C. B. Bohn, general manager of the same firm, were present to represent that part of the aluminum industry most closely in touch with the automobile trade. As luck would have it, Louis Chevrolet has just completed his all-aluminum racing motor and the aluminum chiefs enjoyed an hour spent on an outlying road where 90-mile-an-hour joyrides were indulged in, the engine showing a splendid amount of life.

Left—A. V. Davis, President the Aluminum Co. of America. Center—E. E. Allyne, President the Aluminum Castings Co. Right—W. P. King, Vice-President the Aluminum Castings Co.

Large Attendance for Paper

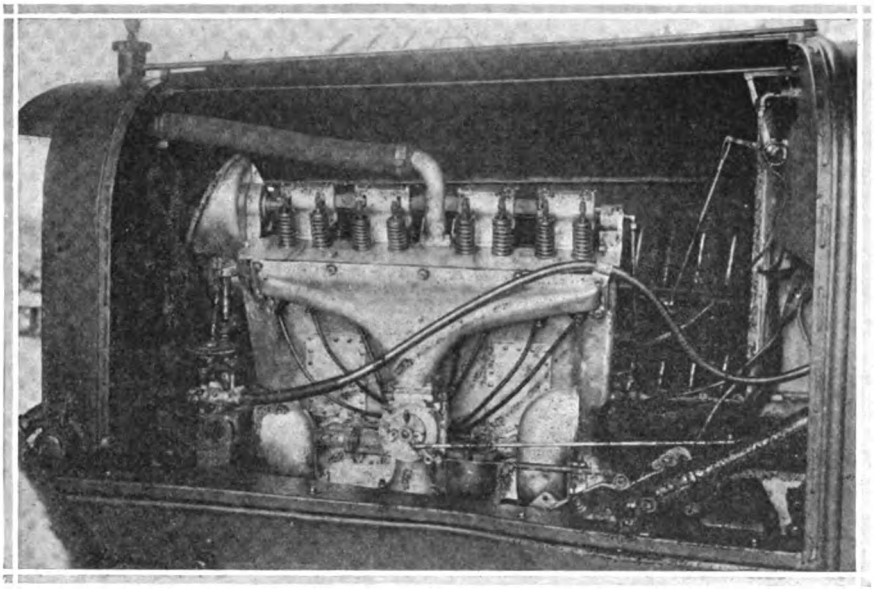
The convention hall at the Pontchartrain Hotel was crowded when, after a brief business session, J. E. Diamond read the paper which was published in THE AUTOMOBILE last week. As soon as he had finished, A. V. Davis was called upon to talk on market matters and the following gives his remarks in condensed form:

I want to say, most emphatically, having been with the Aluminum Co. of America for twenty-six years, that it is not only the desire, but the intention, both now and always, that the Aluminum Co. of America will make all the aluminum that anybody in the United States wants to buy. So that, so far as any future shortage is concerned, if you will only give us a chance and let us alone, we will soon be in the position that we have been in for many years, of making more aluminum than you gentlemen are willing to buy. I suppose that you would hardly believe that March, 1915, was the last month for a period of considerably over five years that the Aluminum Co. of America did not make more aluminum than you gentlemen bought, or any other gentlemen in the United States. Month after month we stocked aluminum, until we went into the month of April, 1915, with not only the biggest stock of aluminum that we ever had, but the biggest stock of aluminum that was ever known in this world. If you gentlemen had been willing to buy, during the last four or five years, considerably more, I can safely say that we would have made considerably more, but we made at least all that could be sold, or at least, all that we were able to sell.

Then in April, 1915, came the beginning of the revival of business. The war had already broken out, but in this country we did not, in general lines at least, feel the effect of it until April or May. Then our stock of aluminum began to be depleted. There were several causes for that, all working to the same end. The first was that the consumption in this country began to jump up very materially. War orders for this, that and the other thing; war orders for automobiles; war orders for automobile trucks; the general revival of business, all tended to make a very substantial increase in the consumption of aluminum. Furthermore, the war itself shut off the importation of aluminum; and there I touch what is to us perhaps a very tender subject, as you can easily understand. We recognize the right of anybody to buy aluminum wherever they wish. We certainly do not pose as the owners of the aluminum industry, although we are proud to say that we are the greatest in the aluminum industry; but, of course, we cannot very well maintain plants of a sufficient size to make enough aluminum to supply this country, and wait patiently for five or six or seven years, until, for some reason or other, there happens to be a shortage, when we can start up those plants, and run them for a year or two until the foreign importation comes on again.

Cessation of Imports Causes Shortage

So far, therefore, as the cessation of importation has anything to do, and it has a great deal to do, with the present shortage, that is something over which we have no control. I feel in a rather delicate position, representing the only manufacturer of aluminum in the country. I wish there were twenty-five others, while I am speaking on this point. Then I could talk about the aluminum industry very much as you can talk about the automobile industry, without seeming either egotistical or seeming to beg for favors. But it is a matter of fact, as you all will see, and must see, that whether we are talking about dyestuffs, or whether we are talking about aluminum, or whatever we are talking about that it is a very difficult thing for the American manufacturers of any product to prevent or to avoid shortage in their particular line, unless, year after year, when there is



The aluminum motor in Louis Chevrolet's special 300 cu. in. racing car, now being tested at Indianapolis

no shortage, *the American consumer buys of the American manufacturer.*

Canadian Plant Under Embargo

Another point, which I will just mention because I want to tell you all there is about it, so far as I see it, is that we have a plant in Canada, as no doubt many of you know, and from that plant in Canada we have always brought a very substantial tonnage into this country; but this year, and also for 1916, when we announced our plans and made our contracts to send in this usual and normal amount of aluminum, the War Office in London stepped in and told us that they needed that aluminum worse than you people did, and that no matter what we wanted to do with it, they were going to take it; and we struggled a little bit, with the result that an embargo was issued, and no aluminum can go out of Canada at the present time, and probably that will continue during the war. So that is the condition, which was rather unexpected, and very unfortunate from our standpoint, and equally so, of course, from the standpoint of the industry.

So much for the shortage as it exists; but you are not especially interested in that; perhaps I have dwelt too long on it. The only cure, aside from the cure that I have already mentioned, is for us to make more aluminum; and, in accordance with our practice and our policy for twenty-five years, we started at once to build more plants. We have laid out a schedule calling for an expenditure of considerably over $20,000,000, this year, and next, but, in our business, it takes a long while to get those plants into shape, get them finished, and it will be about May of next year before we begin to get the results of the more recent of these developments; and it will be, we anticipate, December of next year before they are finished.

It is rather surprising, even to me, when I look over the figures, and see that even now we are making 18 lb. of aluminum to 10 lb. that we were making in 1914. We have screwed up the production a little here, and a little there, until we have made an increase of 80 per cent even now; but when we get these new plants going, we will have such a very substantial increase in production, that unless the consumption of the country should be substantially more than it is now, we will be able to supply it, and have plenty to spare, even though none is imported.

That, I take it, is what you want to know, more than anything else. Although I am very sorry that we have not got the plants finished yet, you can easily appreciate that this condition is not altogether our fault—we did not, at least, bring on the war—if you will only be patient, for a little bit, we will have the production, and insofar as that bears upon the plans for the use of aluminum, I will give you the information for just what it is worth, and you can figure out yourselves what you ought to do in the premises. All I can say is that we are doing everything that we possibly can.

How Aluminum Is Made

The chairman also suggested that I should say a word regarding the process of making aluminum. That seems like bringing coals to Newcastle, to speak to a group of engineers on a manufacturing subject; but it is a bit interesting just in this connection, because it will explain to you why it takes so long to complete a plant to make aluminum.

The ore of aluminum exists in great quantities. There is no shortage there. It is only a matter of buying more picks and more shovels to double the output; no trouble with regard to the ore.

The next step is to treat this ore, by a very complicated chemical process, into a pure product, which we know as alumina, being the chemically pure oxide of aluminum. That is, for a plant to make a substantial increase, you have to spend $1,000,000. That, perhaps, gives you a better idea of how long it takes, because you all know, when you start out to build a $1,000,000 plant, it takes a lot of time, no matter how fast you may work; so that even though we had all the power, and all the other facilities, it takes a lot of time to build an aluminum plant, but the real time is consumed in getting the power. If you gentlemen will pay a little more for aluminum, we could afford to make it by steam power, and possibly hustle up the plant a little quicker; but I have not found anybody yet that would pay any more than they had to, for aluminum; so we have to use water power as the cheap source of power. That is the great expense; and the *sine qua non* in the manufacture of aluminum.

Water Power Scarce

In these days, it is not an easy matter to even get water power. Water power on navigable streams is practically an impossibility, as you perhaps know. I am not here to discuss the political side of it, but as Mr. Cannon, the former Speaker of the House of Representatives once put it to me, any water power bill that you could get through Congress, the President would not sign, and any water power bill that the President would sign, you could not get through Congress; and that is just about the situation.

Perhaps you will be surprised to know that there has not been a water power bill through Congress since the early days of Roosevelt as President, *not one.* We started in to get together a big water power on the St. Lawrence River. We have a lot of money invested in it; but until this deadlock is broken between these people who are conserving the interests of the public, and those who are willing to give corporations a little chance, I do not suppose that water power can ever be developed. That shuts the aluminum manufacturer down to water power on unnavigable streams, and those are necessarily small, and require the purchase of large amounts of property, and that takes a great deal of time. Of course, in this country we do not have the power of condemnation. We have, however, just gotten together a very large amount of property in the South, which we anticipate will be enough to supply the increase in the demand for many

years to come, and I might say that this project is not included in our plans for increase for next year, although we are starting on it already, and I think that, if what we are making next year is not enough for the demands of 1917 and 1918, that these other projects that I speak of, in the South, will come along, and it is our intention to push them just as fast as the market will take the product.

Immense Power Needed

But, after you have got the water power together, you then have to develop it. You take in these days, an increase in the aluminum business means 50,000 hp. or 100,000 hp. to be of any real good, and you, as engineers, all know that to develop a 50,000 or 100,000-hp. water power proposition is no easy task, and two years is a very short time for the most favorably located water power. Three years, four years, or five years, is much nearer the average, and that is where the time is all consumed. So that, with us, it is a question of foreseeing the market, which we always try to do. We are always spending money, and trying to get ready, not for next year, but for four or five years from now, and I feel very certain that the plans that we have on foot now will carry us through, even though we do not have the resumption of importation, which, of course, we will have as soon as the war is over.

If there are any questions you gentlemen would like to ask me, Mr. Chairman, I would be very glad to answer them, except as to how old I am, and how much salary I get.

E. E. ALLYNE—It has been suggested that perhaps this shortage may be partially due to the fact that the Aluminum Company of America may have taken on some war orders. I think perhaps some of these gentlemen might be interested in having a statement from Mr. Davis in that respect.

A. B. DAVIS—I can answer that very simply by saying, that we have not sold 1 oz. of aluminum for any war order, directly or indirectly.

After the passing of a hearty vote of thanks to Mr. Davis the discussion of the paper proceeded and the following gives the gist of the remarks made by the different speakers:

Discussion Centers Round Lubrication

A. LUDLOW CLAYDEN (THE AUTOMOBILE)—Relative to oil pumping, Mr. Diamond, in mentioning the growing practice of drilling a small number of holes immediately below the lower ring, has not mentioned the accustomed number; and I believe this number varies considerably. I think it would be interesting to know what, in his experience, the best number of these 3/32 in. holes is.

Another matter on which I am not quite clear, is, to what extent he favors or does not favor the scraper ring.

JAMES E. DIAMOND—Relative to the first question, to my best knowledge, six holes are used. I do not remember seeing a case with any sized piston, where there have been fewer than six used; of course, these being spaced evenly.

Relative to the scraper ring, I am entirely non-committal as to that. If you can get along without it, so much the better; but in a lot of cases, the motor will persist in smoking, and it is absolutely essential and absolutely necessary to go to the scraper ring to eliminate that.

K. W. ZIMMERSCHIED—I do not know much about piston design, and I am not going to discuss it from the design standpoint; but Mr. Diamond made one remark about grinding these pistons. Now, we have had a little experience with grinding as soft a material as aluminum, and I would look for a very bad source of trouble from that. In a material as soft as that, you will very likely get material from the grinding wheel embedded in the aluminum, and that acts as a lapping agent on this wall of the cylinder, so that with that type of metal, I should say, by all means, the machining or lathe operation would be better.

With regard to the coefficient of friction, I do not just follow Mr. Diamond's argument. We have done a great deal of work trying to find what we might call the wear coefficient of steel against steel, and different bearing metals against steel, and so forth, and the upshot of all our experiments has been that if you have got a film of oil there, you do not get any wear; that the wear that comes is due mostly to the fine grit and the abrasive material that gets into the oil after it has been in use for a while, but if you have always clean oil, and always have a film of oil there, you do not get any wear, and hence the coefficient of friction would not seem to have any great bearing on this matter.

Of course, on the question of a standard piston design, we are very keen for that. We certainly hope that the time will come when we can have a series of standard pistons.

Friction Co-efficient Low

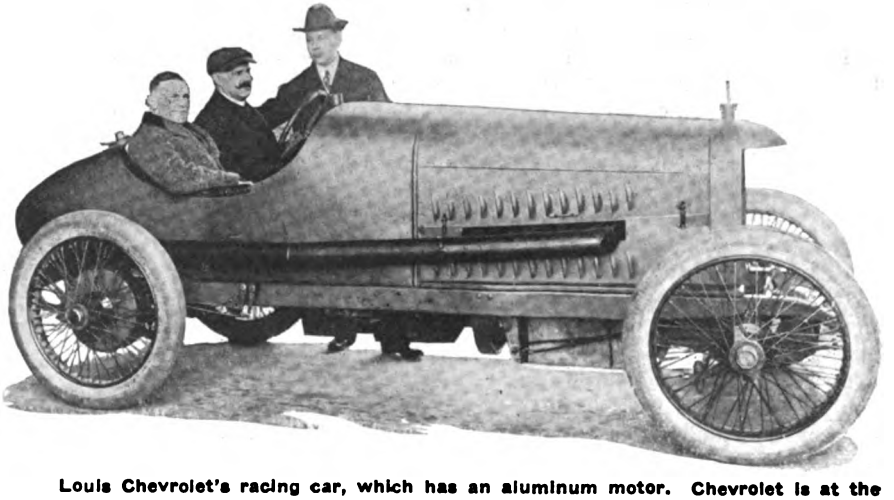
J. E. DIAMOND—That question which Mr. Zimmerschied has brought up, has been put to me before, but the fact remains that in a series of fairly careful tests that we have run out at the plant, we have gotten a coefficient for the aluminum, or rather the Lynite alloy that we use in the Cothias process, of about half that of iron. The conditions were not exactly analogous to those the piston would meet in the motor. We ran blocks, which have a projected area of 1 sq. in., with a load of 1000 lb. per square inch, at a speed, or equivalent speed, of 1000 ft. per minute of travel, we got a coefficient of friction of about 8/1000, that is, 8/10 of 1 per cent. Whereas, with iron, we get in the vicinity of 1.4 or 1.5, that is, 1½ per cent.

I quite agree with Mr. Zimmerschied that if you have a perfect oil film, there ought not to be any wear, but I do not believe you ever get that condition where pistons do not show wear. Pistons do show wear, whether they are iron or aluminum.

On the grinding proposition, if you get the right wheel, there is not very much trouble. Two or three people have solved that problem very nicely, but the fact remains that I think the lathe job is a better job, and cheaper one.

C. C. HINKLEY—I would like to ask Mr. Diamond, just what is going to happen when some of these quick carbon removers use the oxygen flame on the piston head to remove the carbon; if he has taken that into consideration?

J. G. VINCENT—I have conducted a number of tests purposely to determine that one point. I was not worried, be-



Louis Chevrolet's racing car, which has an aluminum motor. Chevrolet is at the wheel; beside him is J. E. Diamond, author of the paper, and standing behind is C. B. Bohn, general manager the Aluminum Castings Co.

cause it was my idea that as soon as the carbon deposit, or whatever it might be, was burned off the piston, the fire would go out. In other words, it requires carbon to cause combustion, and it seems to work out about that way. At least, we have run one motor something considerably over 22,000 miles, and we burned it out a number of times, when there really was not anything to burn out; just to see if any harm would come from putting the flame in there, or attempting to put it in, when there was not any carbon in there, but just a little oil. I personally examined that motor after it was taken down, and I could not find any trace whatsoever of the effects of the burning-out process.

Now, as to the coefficient of friction, I am inclined to agree with Mr. Zimmerschied that the coefficient of friction does not amount to very much, where you maintain a film of oil, of even reasonably good lubricating quality.

L. V. SPENCER—Is there very much of a tendency to offset the wristpin in the pistons? I understand that some of the designs are doing that, for reasons of stopping the slap. I would like to know how many of them are doing it, and what the results have been.

J. E. DIAMOND—I guess it is generally known that the Packard company have offset the wristpin in their pistons for quite some time. I heard of a rather amusing instance the other day, where one company that had been doing a lot of experimenting along that line, had offset the wristpin the other way, and claimed they got better results. So I think this question of slap is very largely psychological.

Objections to Standard Piston

A. P. BRUSH—In discussing some of the points that Mr. Diamond has brought out in his paper, I want to say, first, that, as I understand it, Mr. Diamond has been more of an instrument of transmission than an instrument of origination. His suggestion for the standardized piston, as he says, is largely the result of making a composite picture, so to speak, of the various pistons that he has been called upon to make, so, if I have points of exception to take to Mr. Diamond's paper, I feel it is rather with the rest of you who have to do with engine design, than with Mr. Diamond.

There is one point I should like to ask Mr. Diamond about, because it has a considerable bearing on some of the things I want to say. He says, "Also the piston side pressure may be increased without unfavorable results"; and then, later on in the paper, he makes a plea for a longer piston, for more wearing area. He says that is advisable with an aluminum piston. Those two statements seemed to me a little contradictory. I would like to ask Mr. Diamond if he will harmonize them, please.

J. E. DIAMOND—I think we can reconcile them in this way. In the first place, I have tried to justify the piston which is designated as the hour-glass piston. On that one, the bearing surface is cut away, so that if the coefficient of friction is a factor, and is less than cast iron, we can have a small bearing surface, and at the same time have no greater friction load. On the other hand, I am very partial toward the long piston, where we do not have to use the wiping ring. It is just a question of justifying the hour-glass piston, where it is necessary to use a wiper ring. Do I make myself clear?

A. P. BRUSH—I want to ask about this question of pumping oil, and on the question of the durability and wear of the aluminum piston, and the plea for longer pistons.

It seems to me that this question of piston wear, and pumping of oil, is worthy of very serious consideration, as is the question of standardization. I do not want to be considered a reactionary, but I believe heartily that standardization, if you standardize the right thing, is an excellent instrument of progress; and if you standardize the wrong thing, it is a very efficient obstruction to progress.

Mr. Diamond speaks about the difficulties experienced with aluminum pistons. Speaking of piston slap, as the first point, then the other has to do with the pumping of oil in high-speed motors, when running at low speeds; I think Mr. Diamond meant rather, when running under light loads.

In regard to this question of pumping oil, and wearing of pistons, the number of holes for oil, the elimination groove, my experience with a number of motors does not coincide with the conclusion of Mr. Diamond, or rather, I should say, the conclusion which Mr. Diamond has arrived at by considering the various piston designs which have been submitted to him. I think, before we can come to an intelligent conclusion in regard to this question of piston standardization, we must know whether our engine design, outside of the piston, is up to—shall I say, the standard, or up to the future standard practice.

I am under the impression that the great majority of these piston designs submitted, are used in connection with what I should call a compromise oiling system. That is, an oiling system where the amount of lubrication for any given speed is constant, irrespective of the load, which, in natural consequence, means, I believe, that an amount of lubrication has been chosen which will, so far as possible, meet the conditions of full power and full speed, and at the same time, not give too much excess lubrication at lower powers, and lower or various speeds. It does not seem to me that an oiling system of that kind is quite worthy of standardization. It would seem reasonable to assume that the amount of oil given an engine at any one speed, should logically be in proportion to the work that engine is doing, irrespective of what that speed may be. If we do that, and if, as is entirely possible, the piston is the last working element of the engine to receive lubrication, I see no reason why the lubrication of the piston should not be so accurately controlled, that there ceases to be any problem of over or under lubrication, and a very considerable number of tests bears that out.

I should like to ask Mr. Diamond to what extent has he data as to the kind of oiling system used on the various motors for which they have made the Lynite pistons.

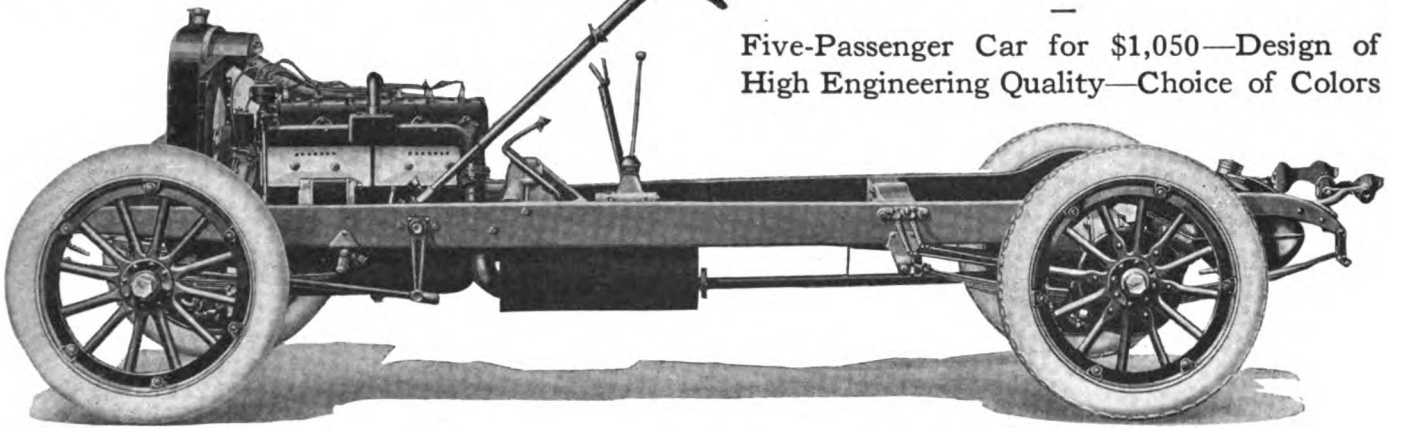
J. E. DIAMOND—That is a puzzler. I know there have been two or three pressure systems. I do not know of any in which the pump is inter-connected with the throttle.

A. P. BRUSH—Of course, the pressure system is also, in a measure, a compromise system, unless it is inter-connected with the throttle. At least, I think we are justified in looking with suspicion upon a proposition to standardize a needlessly long piston, involving a needless amount of material, especially at the present price of aluminum; or a piston in which the piston pin is needlessly far from the piston head, because that problem will also be aggravated by any imperfection of the oiling system.

In regard to the drilling of holes for oil drainage under the lower ring, my experience has been that, with an interconnected oiling system, none are necessary. The practice which I prefer is to have the groove there, not for the purpose of keeping excess oil out of the combustion chamber, but for the purpose of insuring adequate lubrication of the piston pin. That is secured by draining this oil groove below the lower ring, into the ends of the piston pin holes, and providing suitable oil passages, so as to distribute that oil. If the piston pin is loose in the piston, those grooves will take one form; if the piston pin is tight in the piston and loose in the rods, they naturally take another form. But in either case, that is an excellent method of insuring, I should say, copious lubrication of the piston pin, because there is always some leakage around a piston at the moment immediately following ignition of the charge; and those gases leaking by the three packing rings, will, by a process of following the line of least resistance, force a considerable part of oil in that groove through any suitable oil passages, to the piston pin bearing, and with the least oil which will adequately lubricate a piston, that method will insure an abundance of lubrication to the piston pin.

Chalmers Brings Out Light Six

Five-Passenger Car for $1,050—Design of High Engineering Quality—Choice of Colors



The new Chalmers light six chassis which sells for $1,050 as a five-passenger touring car, with color optional. Note depth of channel frame

IT is becoming recognized that it is possible to build a really high-class, well made and finely finished six-cylinder automobile for about $1,000, and the latest addition to this class is a new Chalmers product; a thoroughly handsome five-passenger machine with chassis work of the quality always associated with the Chalmers name. The new car is every inch a Chalmers, it is good to look at, comfortable to ride in, powerful for its size and comparable with the best in engineering quality. With a five-passenger body and full equipment the price is $1,050, and this includes finish in a choice of colors. It is the type of automobile that will appeal to the owner who likes a car with a distinctive individuality.

Briefly, there is a unit power plant with a six-cylinder motor 3¼ by 4½ in., the wheelbase is 115 in. and the springs are long semi-elliptics. Axles are Timken, the new semi-floating pattern being used for the rear. A point of special merit is the frame, which is exceptionally deep and rigid, while the body is as well finished internally as it is pleasing in external lines.

Motor Produces High Power

The overhead valves used for the Chalmers six-40 are not employed for this smaller car, but the new engine is typical of modern L head design, giving its maximum power at over 2500 r.p.m. and at this speed it produces 1 hp. for each 5 cu. in. of displacement. The formula power is 25.4 hp. and the actual maximum over 45 hp., the displacement being 224 cu. in.

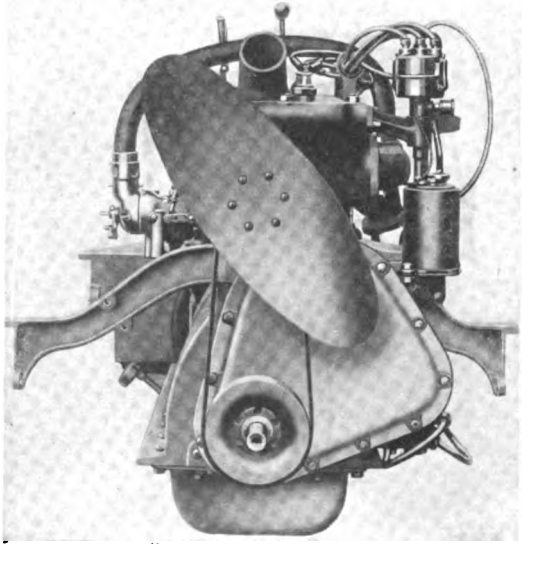
With the desire for eliminating vibration, a very large diameter has been chosen for the crankshaft, the three bearings being 2 3/16 in., 2¼ in. and 2 5/16 in. diameter respectively, reckoning from front to rear, the difference in diameter being to allow for economical, accurate manufacture. Furthermore, as a vibration reducer and efficiency increaser aluminum alloy is used for the pistons, these being made by the permanent mold process. The connecting-rods are quite light forgings, so the total reciprocating mass is small for the bore.

Valves are 1⅝ in. with a lift of 5/16 in., and special attention should be given to the lightness of the tappets, and the method for attaching them. Cylinders and crankcase are a unit casting, but the tappets are assembled in sets of six in two cast-iron racks which are afterwards bolted in place, this making for accuracy and facilitating the assembly. Plenty of space is allowed the valves in every respect, both as to port area and cooling water and around the tappets. A detachable cylinder head makes for accessibility and ease in removing carbon deposit.

Oil Pump a Separate Assembly

One of the neatest parts of the engine is the oil pump and ignition assembly, this being a separate unit bolted to the side of the crankcase at the front end on the left side. Every part is accessible to the last degree and the outside situation for the oil pump helps in cooling the oil. It may be remembered that the Wisconsin-Stutz racing motor has this same feature.

Pressure feed to the main bearings and dip troughs for the remainder of the engine form the lubrication system, while there is an easily visible level gage on the right side of the motor adjacent to the filling cap. As is shown by the photographs, the motor is externally simple, while the drawings show this simplicity to be characteristic of the invisible as well as the visible parts of the engine.



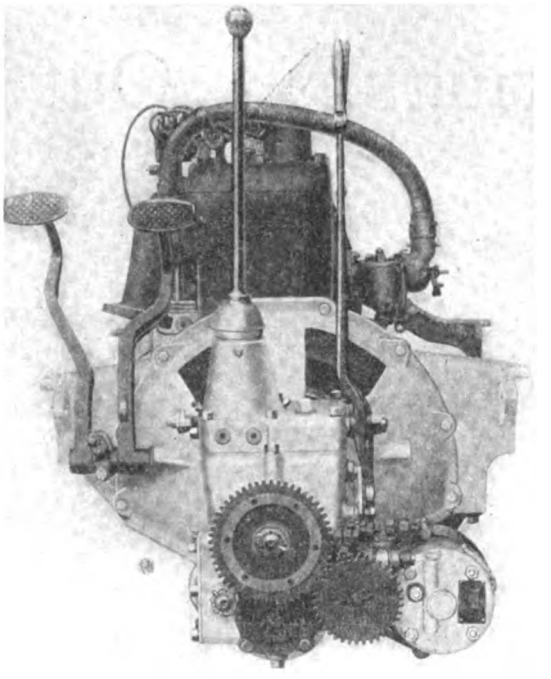
Front end view of new Chalmers six motor, showing simple type of two-blade fan

A peculiarity is the fan, which is probably the simplest two-blade form ever conceived. It is well known that a two-blade type is just as efficient as any other, but it has remained for the Chalmers engineers to show that it can also be the cheapest. A simple piece of stout sheet steel is cut, and riveted to a hub at the middle, and then the ends are bent a little to give a pitch to the blades. The extremely inexpensive driving pulley on the crankshaft is also a clever bit of design as this is practically all press work.

Stampings are used largely throughout the chassis, the Chalmers company having a good equipment for making this class of part. For example, the gasoline tank is pressed from two pieces of steel, thus being immensely strong and cheap withal.

It is on the side of the gearbox

that the starting motor is situated, this engaging the flywheel by a Bendix pinion. The motor is of Westinghouse manufacture and the generator takes its drive from the same pinion as that connecting with the oil pump and ignition assembly. Using this location for the starting motor adds to the space around the engine, and thermo-syphon cooling being employed also relieves the power plant of an accessory. The distributer is a Remy product and the carbureter a 1-in. Stromberg.



Rear end view of Chalmers light six motor, showing mounting of starting motor beside gearbox. Note shaft for ignition drive at left of motor

Light Clutch Aids Gearshifting

Bolted to the motor are the three-speed gearset and the clutch, the latter being the same dry-disk pattern used on other Chalmers models. The inner part is very light in weight, this aiding gearshifting to a pronounced degree and a generous use is made of stamped parts. Having multiple springs the adjustment is very easy, and all parts of the clutch are accessible from beneath, the flywheel being inclosed only as regards the upper portion.

In the gearset the outstanding feature, apart from a general compactness, is the size of the Hyatt roller bearings used. Oil is the recommended lubricant, not grease, and there is a brass cock to gage the proper level. There is a plain bearing at the rear end of the main shaft to take thrusts due to gear shifting or to the propeller shaft, so that the ball bearing in the clutch and the thrust washer on the front part of the main shaft are practically the only ball bearings used in the car, since the axles are Timken equipped throughout.

Hotchkiss drive is used, with a tubular propeller shaft, the rear springs being half elliptic 54 in. long and 2 in. wide, and the rear axle is the new Timken semi-floating pattern with spiral bevel drive and brake drums 12 by 2 in. The gear ratio on high is 4.75 to 1, and the tires 32 by 4 in. so the motor speed is fairly high, the maximum peak of the power curve being reached at a little over 50 m.p.h. At 1000 r.p.m. the car speed is 20 m.p.h. and at 1000 ft. per min. piston speed the car rate is just 15 m.p.h. and the displacement per mile is 670,000 cu. in.

The new axle is typically Timken, having the pressed steel case and taper roller bearings throughout, but the road wheels fit directly upon the ends of the drive shafts. Brakes are, of course, both internal and external to the same drums, the inside brakes being expanded by a cam action and the regular Timken adjustable toggle is used for the contracting brake.

Strong, Light Frame

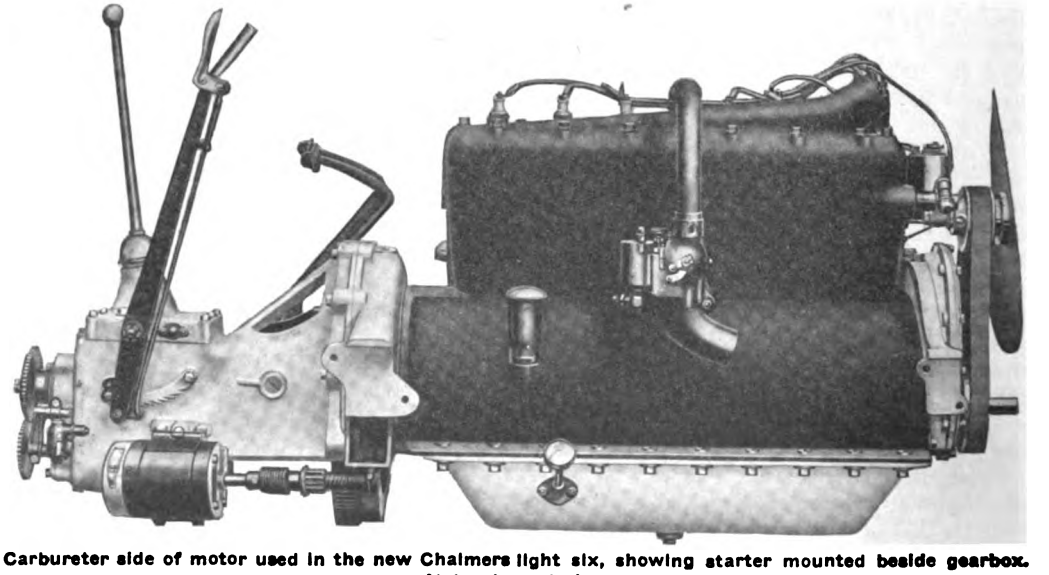
It has been mentioned that a feature of the car is the strength of the frame which is no less than 5 in. deep at the center and for the larger part of the length. Quite a thin steel is used, the thickness being only ⅛ in. and the section is 2½ in. wide. Over the rear axle the frame sides are raised in a short curve, and to give increased rigidity at this point the top and bottom flanges are bent over a little on their edges, so putting a kind of bead on the edge and stiffening the channel section just as a bead on the edge strengthens a fender.

Steering is by worm and full worm wheel, with an eccentric adjustment for taking up slack, and the connections are laid out well, ample size being given to the ball joints and yokes. The front axle is a Timken with taper roller bearings for the road wheels.

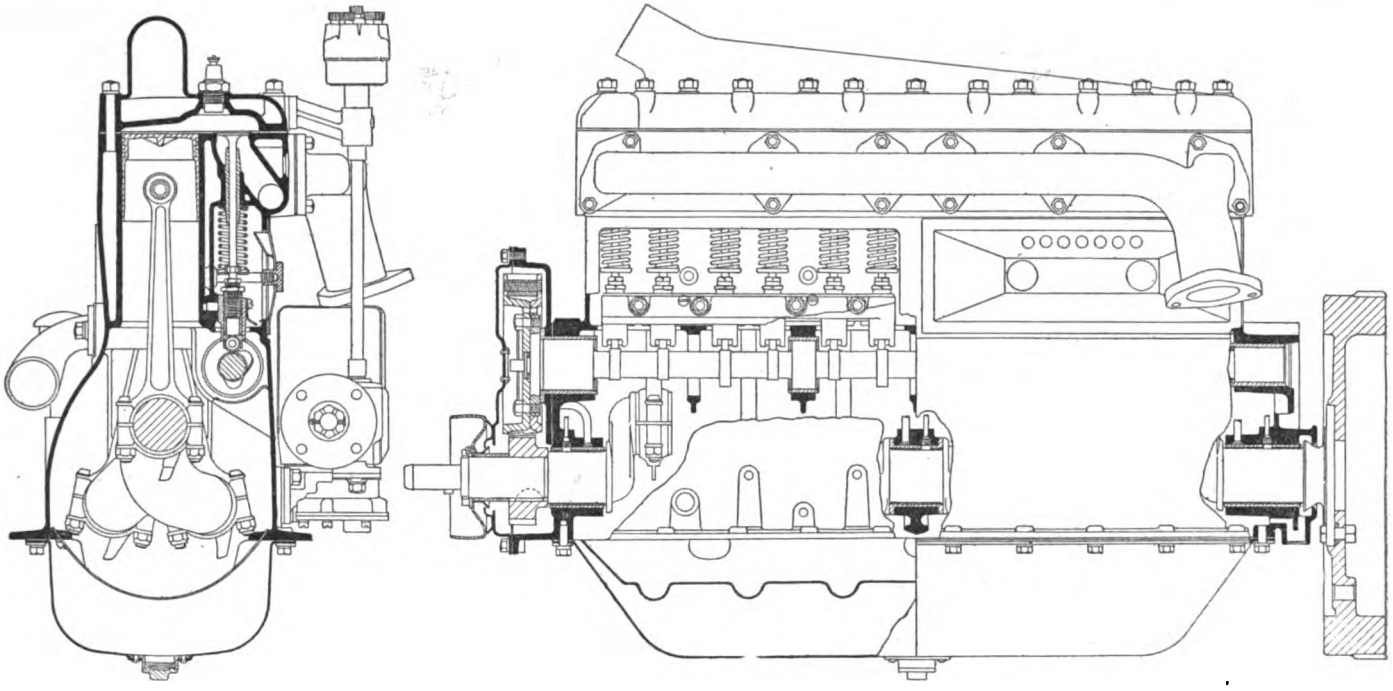
Before passing to the body, mention may be made of a detail of manufacture which should be much appreciated, this being the employment of a wiring unit, all wires being inclosed in a single outer tube. There is no junction box, since the wires attach directly to terminals on a plate which sets in the cowl board and carries the switch, ammeter, etc. It is a matter of minutes only to remove this wiring unit and replace it by another, so if any fault should develop it is as easy to rewire the car as it would be to change a tire almost.

In external appearance the new Chalmers is a reduced scale model of the six-40. It has just the same graceful outline, and the hood and radiator are so alike that it is only in the presence of a six-40 that the difference in size becomes noticeable. At present only the five-passenger type will be made, but a roadster is in preparation. Inside, the front seat is wide enough to accommodate driver and passenger without cramping the former. Sitting at the wheel it is found that the levers are within easy reach, that the lamp switch which gives control of the dimmer can be operated without stretching and that the pedals have a light touch. In the tonneau 46½ in. width is allowed the three occupants, and there is leg room enough without a disproportionate amount of floorspace.

Upholstery is leather with a bright finish, the top is of



Carbureter side of motor used in the new Chalmers light six, showing starter mounted beside gearbox. Note clean design



Chalmers new high-speed, light six engine. The extremely light tappets, the sturdiness of the crankshaft and the method for mounting the oil pump and distributer are distinctive features of this new engine

heavy material and clips neatly to the top of the windshield when erected.

Undoubtedly one of the most attractive things about the car is the really excellent paint work, the colors, blue or dark red or green, are good, rich tints and the hood is painted too, not enamelled.

The fenders are a smoothly rounded shape and the whole machine is distinctly better than its photograph, a thing which is not an invariable rule. As to equipment, the rear tires are supplied with non-skid treads and all the usual accessories are included.

A Car with Character

It is not easy in a printed page to give an idea of how powerfully this car creates the impression of high quality. The design, on examination, shows excellent engineering, up-to-date in every particular, and yet free from debatable points. It is above everything else a sane design. The body is well upholstered and well molded, while having a highly finished exterior. The control is arranged conveniently; the fittings are all thoroughly good.

Yet this statement is hardly sufficient to explain why it is that the first sight of the new model stirs the imagination immediately. At once it is obvious that this, comparatively small, comparatively inexpensive machine is one that the wealthiest man would own with the same satisfaction in his purchase that he could bestow upon a much more costly car.

Both sides of the 3⅛ by 5-in. four-cylinder block motor used on the new Overland 75 which sells for $615

New Overland Four Ready

Model 75 with 3 1-8 by 5 Block Motor, Electric System and Cantilever Rear Springs at $615

OVERLAND'S new four-cylinder model 75, which has been expected for several months, is now ready. It is a typical Overland design with a 3⅛ by 5 four-cylinder block motor and sells at $615 with touring body and $595 as a roadster. It has 104-in. wheelbase, 31 by 4-in. tires, electric starting and lighting with switch box on the steering column, cantilever rear springs, cone clutch in the flywheel and three-speed rear axle gearset. Left drive and center control are used.

Big Production Planned

The plan of the Willys-Overland Co., Toledo, Ohio, is to make these cars on an enormous scale, this being a big factor in setting the price, undoubtedly. However, the point is also emphatically made that the car is not to supersede any other model, the present $750 model 83 being continued on as large a basis as heretofore. It will also not have any effect upon the output of Willys-Knights or of the six.

Economies in the manufacture of the new Overland 75 are seen everywhere in the new plant which has been erected especially for the making of this model. Progressive assembly schemes of almost astounding magnitude are installed, and this, together with the many design features of the car which have been worked out to make an efficient vehicle and at the same time render manufacture as simple as possible, give some inkling of how the big concern is in a position to make the vehicle at the price.

Differs from Former Practice

One has but to inspect the mechanism of the car to realize that it is different from former Overland practice. The motor is a block with cylinders and crankcase in unit and the head detachable. Chains drive the magneto, camshaft and generator. The rear springs are cantilevers, and though the gearbox is in unit with the rear axle as in other models, the axle and the gear assembly are new in design. Many of the features of these parts are the result of the quest for quick manufacture and assembly.

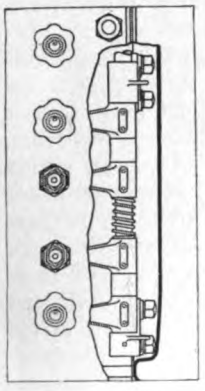
Motor Is Compact

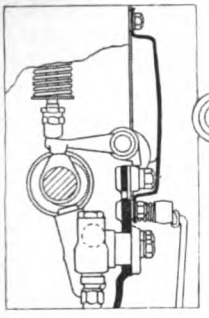
The motor is exceedingly compact, and lends itself well to quick assembly due to the way the parts are designed. For instance, the casting of all the cylinders and crankcase in one piece has not only the advantage of rigidity of construction, but it is at once apparent that one operation at least is done away with—that of combining crankcase and cylinders. There is no intake manifolding, the carbureter simply bolting to an opening at the center of the casting below the exhaust manifold. The gases get to their respective cylinders through cored passages within the block. The cylinder head carries the water outlet connection, the spark plugs and the priming cups. A single cover plate goes over the valve tappet chamber. This in place, there is nothing exposed on the right side but the carbureter, exhaust manifold and magneto. On the left are the oil level gage, the water inlet connection and the generator.

Although the formula rating is 15.64 hp., the 5-in. stroke gives the engine a good displacement—153.4 cu. in. The developed power is 28 at 2000 to 2400 r.p.m., and the advertised power 20 to 25 hp. The pistons are light, as are the rods and their assembly. With a crankshaft 1⅞ in. diameter, the light

Features of New Overland

Motor	Four-cylinder Block
Bore and Stroke	3⅛ by 5
Formula Horsepower	15.64
Maker's Rating	20-25
Electric System	6-Volt Auto-Lite
Gearset	Three-Speed, on Axle
Wheelbase	104
Tires	31 by 4
Springs	Cantilever rear, Semi-elliptic front
Touring Car	$615
Roadster	$595





Motor of the new Overland. The two small diagrams on left show details of the original valve operating mechanism in which there are no push rods

reciprocating parts make high speed attainable with no effort and with a commendable lack of vibration. For instance, the piston and its rings weigh 1.9 lb., and the connecting-rod complete with bushing and cap comes to 1.5 lb. Thus a complete piston and rod assembly totals 3.4 lb., which is very light. The pistons are of cast iron, have the pins clamped in the rods and carry two concentric rings each.

Valves Are Large

Valves have a 1 9/16-in. clear opening and lift 5/16 in. The clear diameter is one-half the bore of the cylinders. One noteworthy feature of the valve assembly is the method of valve actuation, and the ease of adjustment. There are no tappets in the engine. Interposed between the valve stems and the cams are rockers pivoted on a rocker shaft just inside the valve compartment and readily accessible. The adjustment is on the lower end of the valve stem. A round-end nut screws to the end of each rod, and is held by a lock nut. This adjustment is usually on the tappet in designs where tappets are used. The rockers relieve the valve stems of any side thrust, and they also make the valve adjustment very simple. Should it be required to take the rockers from under the valve stems, it is but the work of a moment. They are free on the rocker shaft within sufficient range to allow them to clear the valve rods. Springs hold them against shoulders on the rocker shaft, and by pushing them along the rocker shaft against the spring pressure they are freed from the cams and valves. The whole rocker assembly bolts to the side of the cylinder casting so that it is immediately within reach when the cover plate housing it and the valves and springs is removed.

Two-Bearing Camshaft and Crankshaft

Both the camshaft and the crankshaft are carried on two bearings. The latter is assembled through an opening in the flywheel end of the crankcase, a plate here carrying the bearing and closing an opening that is large enough for the shaft to pass through. With a diameter of 1⅞-in., the front bearing is 2⅝ in. long and the rear 3 in. long. Connecting-rod bearings have the same diameter, and a length of 1¾ in. The camshaft front bearing is 1⅛ by 2⅝ in., and the rear 1⅛ by 1¾.

At the center of the camshaft there is an extra cam which operates a plunger oil pump that keeps a constant level of oil in the individual splash troughs, drawing its supply from the oil reservoir in the base plate of the engine. A very legible float oil gage on the left side of the engine shows the amount of lubricant. It rests on the top of the crankcase, bringing the indicator well up so that it is no trouble to read when the hood is raised. This gage housing also acts as the filler.

Roller Chain Camshaft Drive

Drive of the camshaft, magneto and generator is by chains, of which the inner one is a triangular drive with an idler to keep it tight. This chain runs over sprockets on the crankshaft, camshaft and magneto shaft. Outside of this is the chain that drives the generator from an outer crankshaft sprocket. The idler works against the outside of the chain, between crankshaft and magneto sprockets. A coil spring with a tension adjustment draws on the end of a small yoked member that carries the idler. The arms of the yoke pass around the chain and sprocket, making a good mounting. To still further strengthen the idler mounting and keep it in position, there is another member, pivoted at its upper end to the cylinder casting, and having an arm running to the sprocket center on either side. The scheme of this construction is brought out in the drawing of the front of the engine. There is means for taking up any slack in the generator chain at the generator end. The whole chain assembly is compactly housed, and due to the fact that the roller chains are not as wide as silent chains would be, this housing is not so thick as the latter would require it to be.

Two-Unit Electric System

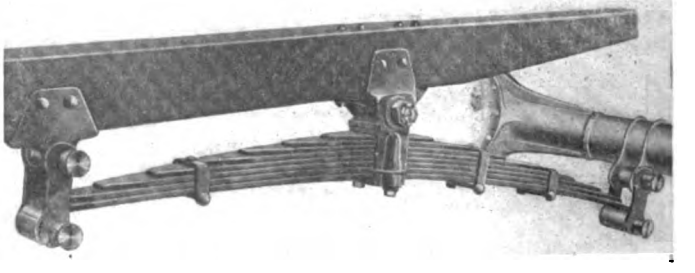
Auto-Lite two-unit starting and lighting are incorporated. The drive of the generator and its position have already been touched upon. This unit runs at 2 1-5 engine speed. The starting motor, geared 11 to 1 to the teeth on the outer rim of the flywheel, is equipped with the Bendix automatic shift which has already been described in detail. In starting, all that is necessary is to press the starting button, when the spinning of the armature shaft sends the driving pinion into mesh with the flywheel, it disengaging automatically when the engine starts under its own power. This unit is carried on the right rear side of the engine close up to the flywheel as shown in the photographs.

Three-Point Suspension

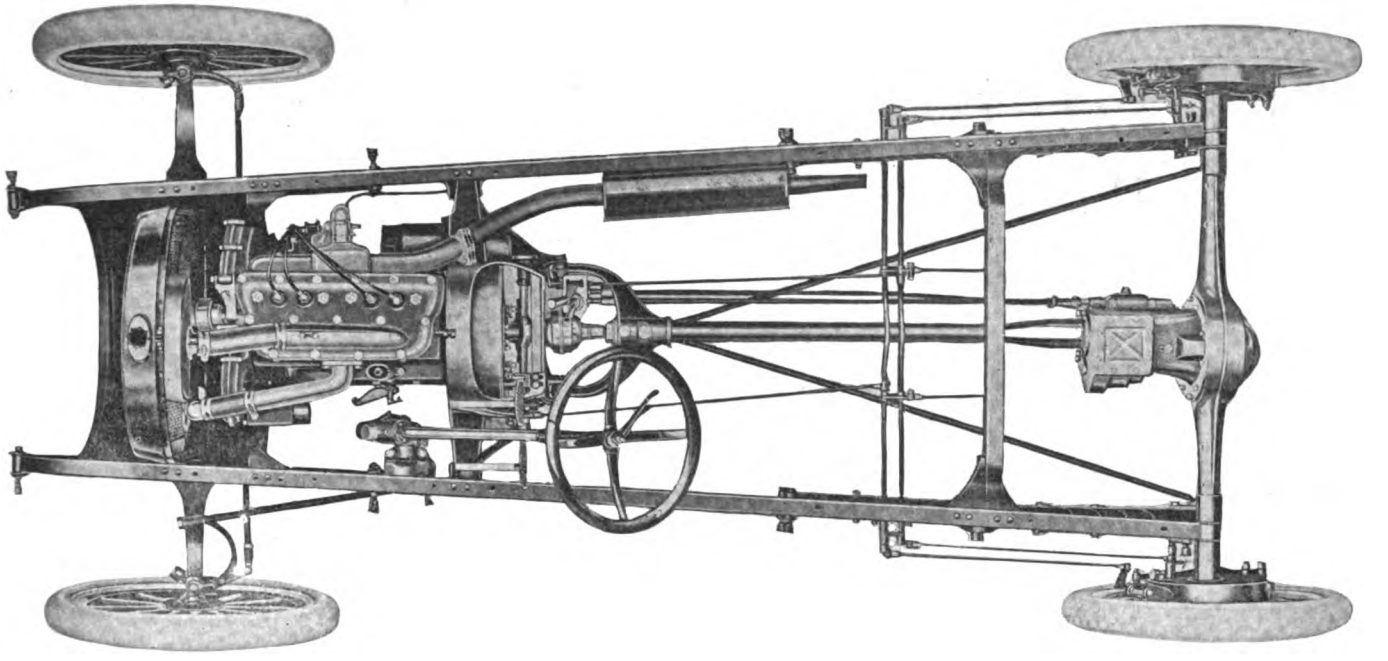
Three-point engine suspension is attained by resting the front on a frame cross arm, and bolting the rear of the motor to an arm construction that performs the functions of partially inclosing the flywheel, carrying the clutch throw-out rod, the pedal and gearshift controls and acts as the support of the ends of the yoke which is the termination of the torsion tube. This makes a nice assembly unit, the rear motor supporting arm feature being only one of its several parts.

Drive is characteristically Overland, with the hinged yoke carrying the front of the steel torsion tube, the rear end of which is flanged to the front of the gearbox. The clutch is leather-faced, on an aluminum cone with spring inserts under the leather and three engagement springs equally spaced. There is a small adjustable clutch brake with a fiber facing that acts against the clutch cone when disengaged, stopping it from spinning.

Compactness of design is notable in the gearset, which has one very interesting feature. The three countershaft gears



Cantilever rear spring used on the new Overland



Overland 75 chassis showing mounting of block motor and rear axle gearset. Note cantilever rear springs mounted under frame

are forged in one piece, the advantages of which from a manufacturing standpoint are readily apparent. This forging is made with a hollow center and there are two Hyatt roller bearings between it and a shaft which is fixed in the gearset housing. Thus instead of attaching three separate gears to a shaft and then allowing the shaft to revolve in bearings at either end, the shaft is stationary and the gears run around it. Fellows gear shapers make short work of the cutting of these gears.

The rear axle has a pressed-steel housing and there are no truss rods or other braces. The bottom and top of the housing are ribbed on the outside to take care of bracing, making a substantial construction. Ball bearings are used in the axle's internal construction, and the design is what is termed a one-bearing floating type. The entire weight of the car is borne by the housing, the axle shafts taking none of it. The axle shafts, which are squared into the differential, have driving flanges integrally forged and these bolt to the wheels. Thus the shafts can be withdrawn entirely without disturbing the wheels in any way. Ample provision is taken against oil leakage out of the axle by felt washers at proper points.

Front axle design is entirely new to Overland cars. It is of the type known as the inverted Lemoine construction, whereby the wheel spindles are suspended from the top of the steering knuckles instead of from a point between the arms of a yoke, as in the more conventional design. There is no yoke support for the knuckles, simply a single support on the end of the I beam. The design simplifies the forging and makes a nearly straight axle. It allows the car weight to be low in relation to the wheel bearings, assisting steering.

Cantilever Rear Springs

Mounted directly under the side members of the frame, the rear springs are full cantilevers, 42 in. long by 2 in. wide. They are trunnioned at the center, and shackled at front and rear. The rear support is below the axle housing, serving to bring the suspension low down, which is desirable. These springs have been so designed that they give exceedingly easy riding qualities to the car.

A straight taper from front to rear is given the frame. It is simple in form, there being a cross member at the front, and another three-quarters back. No cross piece is used at the rear, this not being needed in addition to the member just a little forward. This member, by the way, is located at the point where the cantilever springs attach to the frame, strengthening it where support is needed. The taper of the side rails is such that the body is given good support throughout its length.

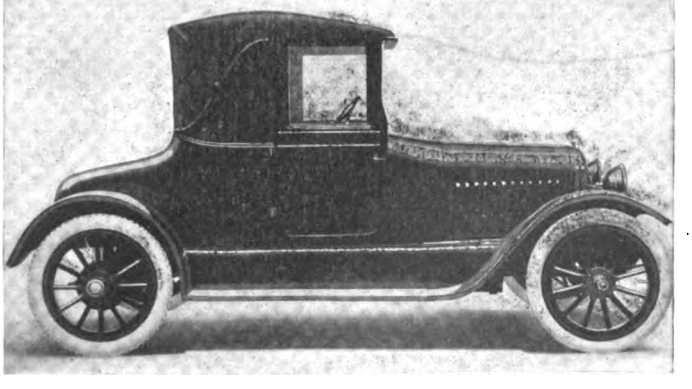
Crowned fenders of sheet steel are fitted, these adding their part to the general appearance. The standard body finish is black, and the upholstery Fabrikoid. Equipment is very complete, taking in such items as demountable rims, one-man top, speedometer, electric horn, and all the little fitments that go to make up the finished car of to-day. The gasoline tank is in the cowl and the filler pipe on the dash.

—

New Grant Roadster and Cabriolet

The Grant Motor Co. has added to its line a new cabriolet at $1,025 and a new roadster at $795. Both new models are mounted on the standard six-cylinder chassis which remains unchanged except for the substitution of special roadster springs scientifically designed from the standpoint of roadster weight and three-passenger carrying capacity.

The cabriolet windows lower for ventilating and are equipped with anti-rattle devices and the windshield is also adjustable to a variety of positions. The back of the body opens up its full width, providing unusually large storage space with ample room for storing extra tire and demountable rim in addition to luggage, repair kits, tools, etc. Like the touring car, the new models are finished in dark Brewster green with black fenders, hood and running gear.



New Grant cabriolet which sells for $1,025

The History of the American Automobile Industry—4

The Development of the Electric Vehicle from 1800 to 1880, Whence the Present Practical Era Dates—Steam Vehicle Progress from 1825 to 1870

By David Beecroft

¶ Review—Last week the development of steam vehicles in America up to 1810 was told, at which time the advent of road building was at hand. A brief review of early road building was included, which review, intended to show why motor vehicle progress was held back in America by lack of roads, is continued in the opening paragraph this week, after which is resumed the progress in motor vehicles in America from 1825 on.

THOMAS TELFORD, England, 1757-1834, was one of the greatest civil engineers of his time, He built the road from Warsaw to Brest for the Austrian Government, and served on many canals, locks and bridges. In 1803 he was engineer for the construction of 920 miles in the Scottish highlands and later perfected communication between London and Scotland and the north English towns, as well as in the more inaccessible parts of Wales. The Telford construction is very similar to the Tresaguet, consisting of a foundation of large broken stones, carefully set, on which the finer broken stone is placed. The Telford system has been very little used in America excepting where the soil has been of such character that it would not support the broken stone without a foundation of heavier stones to assist.

First Street Cars, 1832

Reverting again to the progress of steam road vehicles in America, in 1825 T. W. Parker is said to have made a steam vehicle with three wheels that were 8 ft. in diameter. The motive power was a two-cylinder steam engine. It was only 7 years later, 1832, that John Stephenson built the first street cars ever to be used in America and started running them on the streets of New York City.

At this time the influence of development of other forms of motor vehicles was beginning to be noticed in America, an indication that steam was not going to have clear sailing so far as road vehicles were concerned.

Electricity Grows in Importance

It was at this time also that the influence of electricity was beginning to assert itself, so that as far back as 1840 we see the struggle among steam, internal combustion engine types and electric types starting an industrial warfare that raged with more or less energy until the opening years of the twentieth century, when the ascendancy of the internal-combustion type of vehicle had established itself, when steam was on the wane and the electric type was in second position. The progress of steam vehicles must be set aside for the moment and a few paragraphs inserted on the activities of electricity and also efforts at patenting features of the explosion engine.

While Benjamin Franklin, in 1751, and Joseph Priestly, 10 years later, suggested firing guns by electricity and many minor electric phenomena were known, practical electricity dates to 1801, when Sir Humphrey Davy produced and studied the arc light in England. In 1802 Romagnosi, an Italian, discovered that the magnetic needle was deflected by the electric current. In 1831 the principal facts of electric induction were discovered by Sturgeon, Henry and Page, who followed Faraday's discovery of electric induction in 1831. S. F. B. Morse of New England conceived the electric telegraph in 1832 as he was returning from Europe and exhibited his apparatus in 1837. From this time a wave of electric progress was started which became evident in several countries.

An Electric Boat in 1837

W. Sturgeon, a British inventor, carried his electric experiments further and tested an electric boat in 1837, as did Prof. M. H. von Jacobi on the river Neva at St. Petersburg in 1839. Von Jacobi's motor was of about 2 horsepower driven by a Grove primary battery.

In 1840 Davenport & Cook of Vermont, United States, made an electric motor of the walking-beam type and drove a printing press with it. Their battery used zinc and copper plates and a blue vitriol solution.

A Scotchman, Robert Davidson, in 1842, ran a 5-ton electric locomotive at about 4 miles per hour, using as his source of current a primary battery of seventy-eight cells. The plates were 13 in. square, of zinc and iron, and a sulphuric acid solution was employed. Thus far it seems not to have occurred to anyone that two electromagnets could be combined and give better results than one used in conjunction with a permanent magnet, but in 1844 Dr. W. F. Channing, a Boston electrician, substituted an electromagnetic field for the permanent one commonly used. Two years later King and Starr produced electric light in a vacuum, but Starr died and the matter was dropped.

In 1847 Moses G. Farmer of Massachusetts exhibited a locomotive driven by forty-eight Grove cells of 1 pint capacity each. This little car ran on an 18-in. track and carried two people. Three years later Prof. Charles G. Page of Washington, D. C., used a 16-hp. motor driven by 100 Grove cells, having plates 1 ft. square. This vehicle carried twelve or more people at a time at 19 miles per hour on the W. & B. R.R. between Washington and Bladensburg.

With successes of this kind and an active interest on both sides of the water, it seems to us who are now familiar with electric traction very strange that the devices had to wait so long for public recognition and final success. It must be considered, however, that the wet or primary cells were both expensive and not well adapted for transportation work, and at that time they seemed still to lack suitable means of producing electric power, although the knowledge existed that running a motor by power would convert it into a dynamo and produce a current. Further, the gas engine had not yet been perfected, the steam engine was still very crude and uneconomical, water power was not available at most of the large cities, and even if the electric dynamos had been efficient, the storage battery did not exist and trolley wires were unheard of in their present form. True it is that Henry Pinkus, in 1848, took out a British patent on a sort of third rail so that the car could be driven without carrying its own battery. Lilly & Colton, of Pittsburgh, Pa., in 1847 invented a means of controlling the electric car from the battery station, the current traveling to the car on one rail and back on the other, a method that has not proved very successful."

A Lull in Activity

For the next 30 years electricity made little progress. The telephone was conceived in 1861, but it was over 10 years before its practical life was started under William Graham Bell. In 1879 the practical incandescent light was produced. The first electric railroad was run in Germany in 1881. In 1884 Cleveland, Ohio, was the first American city to have an electric street car system in competition with horse cars; and in 1895 the first electric locomotive was used in America in the tunnel under the city of Baltimore. This brings us up to the time when the practical electric automobile, as we know it to-day, was a reality.

Hot-Tube Ignition Appears

Reverting to 1837 and looking at the progress made in other fields of transportation in America we find that Dr. Alfred Drake, an American whose work extended from 1837 to 1855, brought out what is now known as hot-tube ignition, which in later years found very extended use. Drake's tubes differed from the later forms in that they extended into the mixture in the cylinder and were heated by a flame blown into their open outer ends.

In 1844 Stuart Perry of New York took out United States patent No. 3597, embodying a considerable number of valuable features. He employed liquid fuel and mentions several kinds, but seems to have conducted his experiments with turpentine. His carbureter, called by him a generator, employed heat to convert the turpentine into a vapor which he mixed with about fifty parts of air. He employed compression, flame ignition, air cooling and provided a clutch so that his engine could be started before being connected with the work. Another patent taken out in 1846 shows some improvements and water cooling.

Progress of Steam Vehicles

Resuming again the progress of steam vehicles: The development of steam from 1825 on was very slow in America, it not experiencing the stimulation it received from improved roads in England, so that up to 1860—Civil War days—there is little to record more than sporadic efforts.

In 1835 a machinist in Brattleboro, Vt., built a steam road vehicle that was successfully used on the roads. It resembled an ordinary one-horse wagon and the boiler was made of U-shaped tubes about 1¼ or 1½ in. in diameter, so placed that the lower ends of these tubes served as a grate, while the flame followed them toward the top, the other ends forming an arch or cover to the firebox. These tubes were connected at top and bottom ends by larger tubes or drums and a second drum above the top one served as a steam dome, these drums being about 4 to 6 in. in diameter with the top one somewhat larger. Two cylinders were used, the pistons being about 3 in. in diameter. This was one of the many experiments that were constantly being tried, but which we necessarily omit because they were not known or sufficiently important to be worthy of mention.

A Two-Cylinder Engine

In 1840 J. K. Fisher of New York designed a small steam car, but his British engineer friends advised against it because of the difficulties that had been encountered in England. Later on he took up the work and in 1853 built a vehicle having a two-cylinder engine, 4 in. bore by 10 in. stroke, and developing 15 hp. This vehicle used 5-ft. wheels. Between 1859 and 1861 he made several engines and took many trips with his vehicles.

In 1857 Richard Dudgeon, of Coney Island, built a steam car having two cylinders 3 by 16 in. and capable of running 10 miles per hour on gravel roads. This was exhibited at the New York Crystal Palace and was destroyed there by fire in 1858. Some years later, 1867, he built another, which is still in existence, and has been used frequently in recent years by one of his sons residing at Locust Valley, L. I.

Armored Cars Not New

The Civil War of 1861-5 called the attention of inventors to the self-propelled vehicle for war purposes and *The Scientific American* speaks of steel-clad steam chariots of war which should consist of road locomotives covered with plates and having a rifled cannon mounted on a pivot and protected by a shield platform. Thus it is seen that the armored war-car thought is more than a half century old and probably very much older than that.

The Rostrum

Enlarging Condenser Does Not Affect Spark

EDITOR THE AUTOMOBILE:—Would increasing the size of a condenser increase the intensity, or distance a spark would jump using a given coil and battery? Does the distance that a spark will jump depend upon the magnetic capacity of the core, the ratio of the ampere turns in the two windings, the difference in size of the primary and secondary wire or what?

2—What is the compression in pounds to the square inch in cylinders of modern, well-designed automobile engines?

3—With what type of generator is it necessary to short circuit the field windings to keep them from burning out when the storage battery is disconnected?

4—Is there any automatic device which makes short-circuiting unnecessary, used in any of the systems now on the market?

Ancon, C. Z. E. ALLEN.

—The increase in the size of a condenser over the requirements of a coil would not increase the strength or size of the spark.

2—Anywhere between 40 and 70 lb. per sq. in. absolute.

3—This depends solely upon individual design.

4—Some of the systems, such as the Bosch, are protected by means of a fuse in the field circuit so that if the battery is disconnected and the removal of the fuse is neglected it will automatically blow and protect the instrument.

Burning Paint Requires Care and Skill

Editor THE AUTOMOBILE:—Would you advise burning off present paint on car in order to have change of color from deep navy to grey without varnish? Could finish be kept clean easier without varnish?

Needham, Mass. F. T. R.

—If you have not had any experience in burning off paint do not risk a good car in order to learn how to do it. If you are skillful with the use of the torch, burning is the most thorough way to remove the paint.

Regarding which finish is easier to keep clean, it is just as easy to keep an unvarnished surface clean as a varnished one. The only difference is that a varnished surface has a polished effect, whereas the unvarnished is dull and not so delicate.

Circuits of U-S-L Electric System

Editor THE AUTOMOBILE:—Kindly explain by sketch and description the charging and starting circuits of the U-S-L starting and lighting system?

2—What is the way to find a missing cylinder in an eight or twelve-cylinder motor?

New York City. T. D.

—The two illustrations herewith, Figs. 1 and 2, show a wiring diagram of this system. On Fig. 1 the arrows show the direction of the current flow in all of the circuits when starting and Fig. 2 shows the direction of all the circuits when the car is traveling normally. These marked diagrams should provide you with the information you desire.

The starting switch performs no function when generating. When starting, the plunger, which is represented in the diagram by a bar, connects the three terminals of the starting switch together.

The automatic switch is of the ordinary type which closes the battery charging circuit when the voltage of the generator is sufficient to charge the battery and opens it when the voltage falls below that required to charge the battery.

The touring switch is convenient in stopping the battery charge for long daylight drives when practically no current is being consumed.

2—The best method is by short-circuiting the plugs in each of the cylinders individually while the motor is running slowly. When a difference is detected as soon as the plug is short-circuited it is evident that the motor was previously firing on that cylinder.

Removing Axle Shafts from Olds

Editor THE AUTOMOBILE:—Will you kindly advise me as to the best method of removing the rear axles from the housing on my model A Oldsmobile roadster?

Can these axles be straightened so as to take the play out of wheels?

Can you give me the makes of rims used on these wheels?

Youngstown, Ohio. F. D. J.

—In order to remove the rear axle shafts from the rear axle housing it is first necessary to take off the rear wheels. After this is done there will be found a small lock-nut held to the end of the axle casing by a cap screw to prevent the bearing cup from turning around after it has been properly adjusted to the bearing which runs in same.

The above lock holds in place a

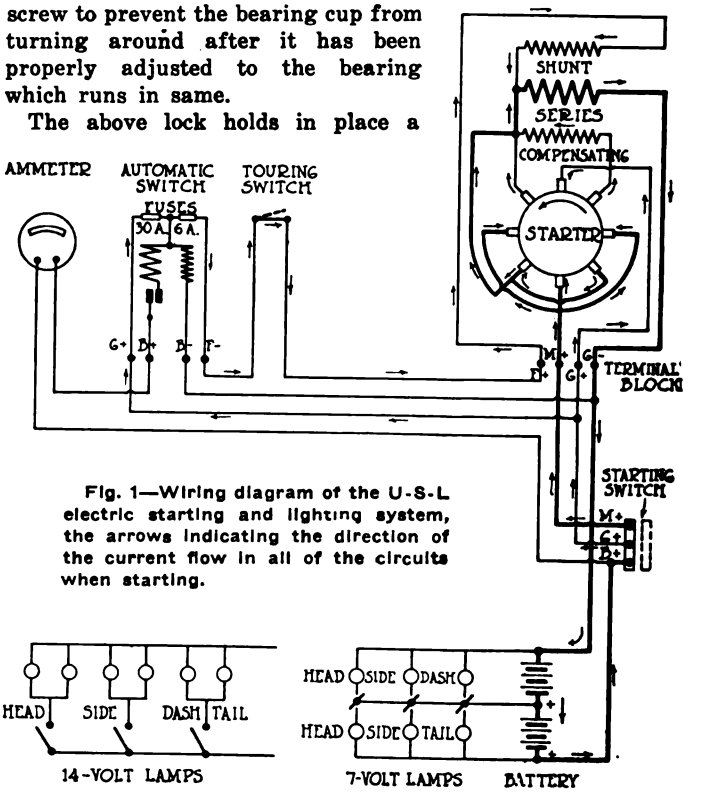


Fig. 1—Wiring diagram of the U-S-L electric starting and lighting system, the arrows indicating the direction of the current flow in all of the circuits when starting.

bearing cup which screws in the end of the axle casing. This cup is threaded with right hand threads and can be removed by the use of a wrench designed for this purpose or by using a small punch and tapping lightly with a hammer until it loosens sufficiently so that it can be turned out the rest of the way by hand.

After this cup has been taken out the bearing can be removed and the axle shafts pulled out.

In regard to straightening bent axle shafts it has been found that once one of these shafts has been bent it will not hold for any length of time. The trouble mentioned in your letter is undoubtedly due to worn out hubs on the rear wheels. It is also possible that the outer ends of the axle shafts are worn. In very few cases has the trouble been found to come from bent shafts. The remedy is generally the use of steel shims unless you desire to replace the parts.

It is impossible to advise exactly the style of rim used on this particular car since at different times the Goodrich, Marsh, Goodyear, Fisk and clincher types were employed. This information can be secured by supplying the number of the car or motor.

Speed Engaged with Lever in Neutral

Editor THE AUTOMOBILE:—We have a 1911 model Brush which has been giving us considerable trouble during the past year and will try to describe this. It seems to have developed during the summer of 1914. The owner could not crank the car as it seemed to be in gear, although the lever was in neutral position. We took the car all down and found the drive gear on the end of the driveshaft had slipped out of place about ¼ in. We cleaned the transmission very carefully, putting the gear back into place. The car ran well again for some time, when the same trouble came back. The car was again taken down and the gear was found to be in the proper place and we could not find anything wrong so we cleaned the transmission and reassembled the car again. The car ran well all last season, and up to about June 1 of this year, when the same trouble returned. The gears were all right and everything seemed to be in place. After cleaning the car it ran all right for a time, but since then have had the same trouble return several times. What do you think may be the cause for this?

Spooner, Wis. G. W. H.

—The trouble you are having is probably that one of the speeds is still engaged while the lever is in neutral. The gearset used on the Brush car is a planetary design using disks in all speeds and no doubt if you will equalize the hand control lever so that it will go the same distance into low speed from neutral position as it does into the reverse, it will overcome the trouble.

It can also be caused from not using the proper oil or grease which would allow the gears to become gummed or sticky. It is therefore suggested that you thoroughly clean out the gearbox with gasoline or kerosene, drain it and then add a new supply of non-fluid oil.

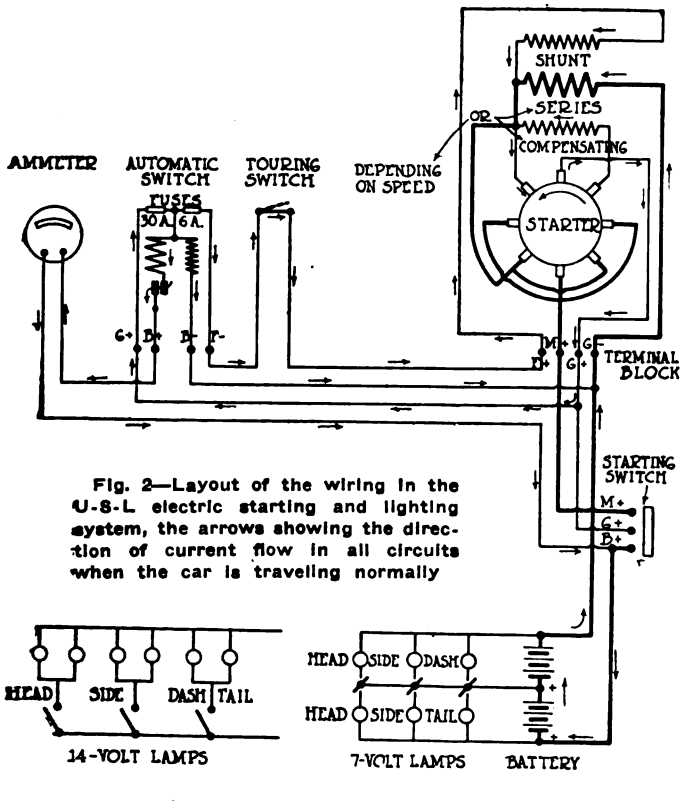

Fig. 2—Layout of the wiring in the U-S-L electric starting and lighting system, the arrows showing the direction of current flow in all circuits when the car is traveling normally

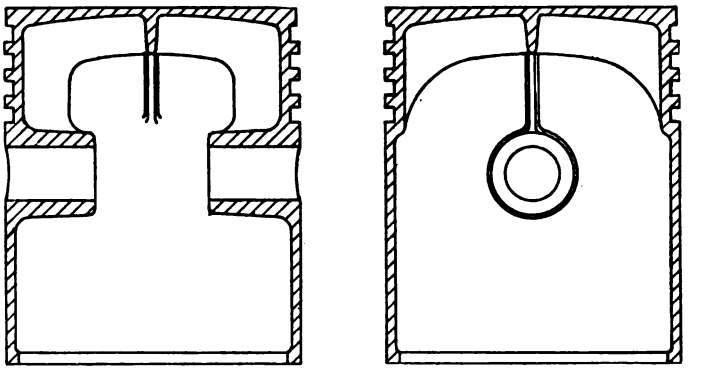

Fig. 3—Illustrating the system of ribbing piston for preventing excessive expansion by dissipating the heat

Aluminum Alloy Pistons for Racing

Editor THE AUTOMOBILE:—Would you advise using aluminum alloy pistons in a racing car using a Buick 17 motor? We now use cast-iron pistons of about 3 lb. and connecting-rods of the same weight.

2—Also, what clearance would you allow for expansion in this motor for races of not over 25 or 30 miles and also have it so that you could run about the city at about 15 on high?

3—Please give us a diagram as to the construction of the pistons on the inside so as to not allow too much expansion.

Saginaw, Mich. B. G. & S. Co.

—Yes, to attain the highest possible speed.

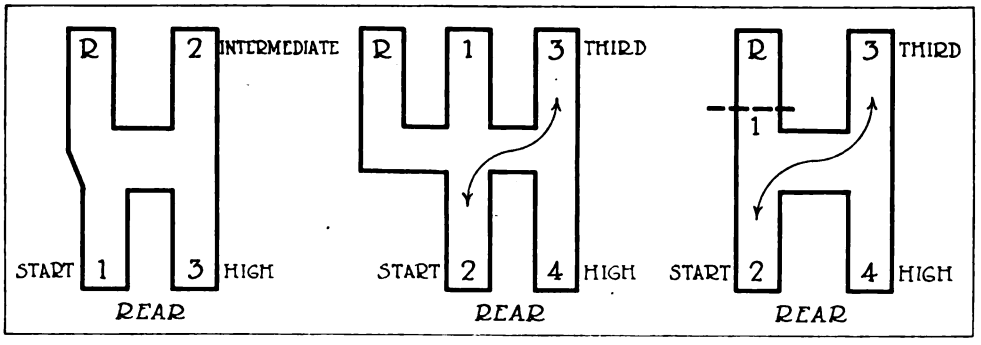
2—For a racing job if the motor is going to be driven at a very high speed, that is, above 60 m.p.h., even for short distances, it would be advisable to allow possibly 0.0035 per inch of piston diameter on the skirt. Possibly as much as 0.005 per inch for at least the first land, tapering back with less clearances on the succeeding one.

3—The best means of keeping the piston expansion down by dissipating the heat would be to put deep ribs across the head. One rib from boss to boss and a transverse rib. The illustration herewith, Fig. 3, will explain what is meant by this.

Probably a Break in Regulator Winding

Editor THE AUTOMOBILE:—On my 1913 Cadillac I have recently experienced a little trouble with my Delco system which baffles me and I would be pleased to have your advice. My storage batteries are in A1 condition, having recently been recharged owing to the cause explained herein.

On pressing the starter switch button on the switch box the current is so weak that the coil in the magneto latch fails to draw the pawl down so that the arm on clutch pedal shaft cannot hook onto the pawl and operate the electric generator switch. On engaging the latch with my finger, however, the batteries will turn over the electric motor (and



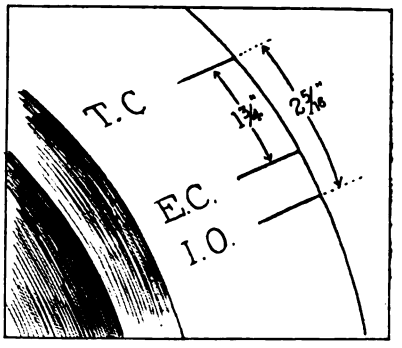


Fig. 4—left—Illustrating the recommended practice in gearshift gates adopted by the Society of Automobile Engineers. Fig. 5—Right—Timing of model 19 Buick by the flywheel face

in turn, of course, the engine) at a high rate, thus proving that the batteries are all right.

But yet when pressing the switch button on top of switch box, the electric motor fails to rotate at all to allow the pinion to mesh with the teeth on flywheel.

The band of the ammeter stands at zero whether engine is running or all lights burning and of course, therefore, neither shows charging or discharging. The engine also misses badly at all speeds and carbureter is all right and distributers, battery and magneto, are in good order and clean. Any suggestions you can offer to help me out will be greatly appreciated.

Branford, Ont. R. T. L.

—While the details you give are not sufficient to render positive the diagnosis of your trouble it seems that the difficulty is that when the starting button is pressed the armature on the motor generator does not revolve so as to permit the clutch pedal to be depressed for meshing the starting gear. The winding of the magnetic latch coil is in series with the starting button and also with the small commutator for generator winding. Across this circuit is connected the shunt field which is the field having the fine winding and this shunt field is in series with a fine winding on the voltage regulator. All this will be readily made clear by noting the wiring diagram which is provided in your 1913 Cadillac instruction book.

When the starting button is depressed the circuit through the winding on the magnetic latch coil and the generator winding is completed and hence the armature rotates, making it possible when the clutch pedal is depressed to mesh the starting gears. Sometimes, however, the small winding on the voltage regulator will break, causing an open circuit in the shunt field. Under these conditions, the generator will not revolve when the starting button is depresed and it is therefore suggested that a new voltage regulator tube be tried in this case.

If the fine winding on the voltage regulator is open, as stated, the matter may be known by connecting the center terminal of the voltage regulator with the left terminal of the voltage regulator. This will short out the fine winding and close the shunt field circuit provided the fine winding on the voltage regulator is open. The car, however, should not be run in this condition but the voltage regulator should be repaired as promptly as possible. Otherwise damage is likely to result to the batteries.

Recommended Practice for Gear Gates

Editor THE AUTOMOBILE:—I wish to call your attention to an article about the late meeting in Detroit of the Safety First Federation published in THE AUTOMOBILE for Oct. 28, page 810. In the right hand column, under the caption, Standard Gearshift Gates, you say: "The successive positions through which the gear-shifting lever has to go in progressing from one speed to another have been standardized by the society and are closely followed by the majority of cars using selective transmissions." Can you inform me as to what this standard is?

I am a car driver of many years' experience; have owned a number of cars and fully realize the danger and difficulty referred to in said article. I have often talked about it and have taken it into consideration in the purchase of cars. At present I am the owner of two cars, each having the system used by the Cadillac, Overland, Studebaker, Regal and others. This seems to me to be the best and most natural position where the gearset is situated at the right hand of the driver.

Washington, D. C. H. E. S.

—The recommended practices adopted by the Society of Automobile Engineers are those shown in Fig. 4.

Buick Timing in Flywheel Travel

Editor THE AUTOMOBILE:—In reading the Rostrum of THE AUTOMOBILE for Sept. 30, I notice that you gave the valve timing of a model 19 Buick for "F. S." of Barberton, Ohio. In your drawing you state that the exhaust valve closes 1/16 in. past top center and the inlet opens 3/32 in. past top center, which is correct in piston travel, but not on the flywheel circumference. As a model 19 has no starter the gear teeth on the drawing might confuse the questioner as his flywheel has none. Below is the correct timing by the flywheel face, Fig. 5.

Newark, N. J. W. C.

Uncertain as to Carbureter Type

Editor THE AUTOMOBILE:—I have a 1907 Pierce-Arrow 28-32 hp. and no one seems to be able to adjust the carbureter correctly. It is of the automatic type and has baffled experts.

2—Is there any way to shift gears silently with the Pierce-Arrow interconnecting device, progressive type?

3—Why is it that the car will run all right on the level, pick up quickly and as soon as it is throttled down to about 15 m.p.h. on every five or six revolutions it begins to miss?

The plugs are all new, valves are ground, etc. Also, on a small hill it seems as though something is holding it back. It simply will not take hills on high.

E. Williston, L. I. M. Z.

—In the year you mention the Pierce company used a carbureter in which the auxiliary air valve was a poppet design held on its seat by a coil spring. The left of the valve was entirely regulated by the weight of the spring and the suction of the motor. In the following year or late in the season this auxiliary air valve was changed to a reed valve design and it is not certain whether the carbureter on your car has the poppet or reed type. In either case it is possible that the throttle valve is worn considerably or that the adjusting needle is scored in the spray nozzle, also perhaps the

intake manifold is leaking through its various joints due to gaskets not being tight or the joints broken from their fastenings.

2—Regarding the shifting of gears the progressive type of gearset was used in that year, the shifting lever being a quadrant directly under the steering wheel. If the gearset is in perfect condition and there is no excessive play between the shifting lever and its various connections to the transmission gear and the car is not accelerated to excessive speeds, the gearshift should be performed quietly for that type of transmission. Of course it must be understood that the standards of quietness in 1907 were not what they are in 1915.

3—This may be either due to carbureter, weak valve springs or ignition. It is impossible to go into any of your questions thoroughly without more data as you do not say anything regarding the condition of the motor and its accessories such as the valves, magneto, etc.

Open Circuit in Armature Winding

Editor THE AUTOMOBILE:—Can you tell me what can be the trouble with my Auto-Lite single-wire system generator? It will not produce current but will run as a motor when the current is applied to it. Everything seems to be all right. What is the cause for the solder melting where the wires are fastened to the commutator?

2—Please explain the relay as used on the first self-starting Cadillac. This one will vibrate, but will not allow the current to pass through.

Clay Center, Kan. G. L.

—The trouble seems to be an open circuit in the armature. That is, one of the connections to the commutator may be loose or broken. The cause of melting of the solder where the wires are soldered to the commutator is impossible to determine without having an opportunity to examine the generator and this should be referred to an experienced electrician.

2—From the quotation which you give, it may be gathered from the words, "first self-starting Cadillac" that this is a 1912 car, as this was the first model on which a starter was placed. There were, however, on this car, two relays—one ignition relay in the dry cell system and one cut-out relay in the generating system, between the generator and the battery. It would therefore, be necessary to know which of these relays you have reference to in order to intelligently answer this inquiry.

Bosch Duplex Ignition System Explained

Editor THE AUTOMOBILE:—Please explain and give full details of the Bosch duplex ignition system.

Lincoln, Neb. P. S.

—The Bosch duplex magneto differs from the independent magneto in that it is fitted with a commutator and in its application requires the use of a small primary coil which is combined with the switch. Aside from these changes the magneto is identical with the independent type which has frequently been described in these columns.

The Bosch duplex coil, which is used in connection with this system, consists of a stationary cylindrical housing containing a single primary coil and in addition a switch assembly. In the coil itself there is an iron core which carries a movable switch plate with both ends of the wire winding connected to metal segment on the switch plate which may be brought into contact with the springs on the connection plate.

With this system the battery aids the magneto at low speeds, the battery current being thrown into phase with the magneto current and thereby assists in producing sparks at low piston speed.

The system above described is the old non-vibrating type. In addition there is the Bosch vibrating duplex ignition, which is a different arrangement. The entire system, aside from the independent Bosch magneto consists only of a low-tension coil, a switch and a battery; these, with the exception of the battery, are furnished by the Bosch Magneto Co. in making up this outfit. The coil is the only part which is special. The method in which this system operates is by effecting an arrangement whereby the magneto circuit is absolutely independent and complete in itself, the battery circuit including both coil and magneto as illustrated.

With the switch in the battery position, the battery and coil are in series with the primary winding of the magneto, thus there is induced in the secondary winding of the magneto armature a very powerful sparking current which, on account of the vibration of the coil appears not as a single spark but as a series of sparks. The current so produced is distributed in the usual manner by a regular distributer. The battery side is not intended to be used separately, but merely as an auxiliary to the magneto for starting. For regular running the magneto operates independently.

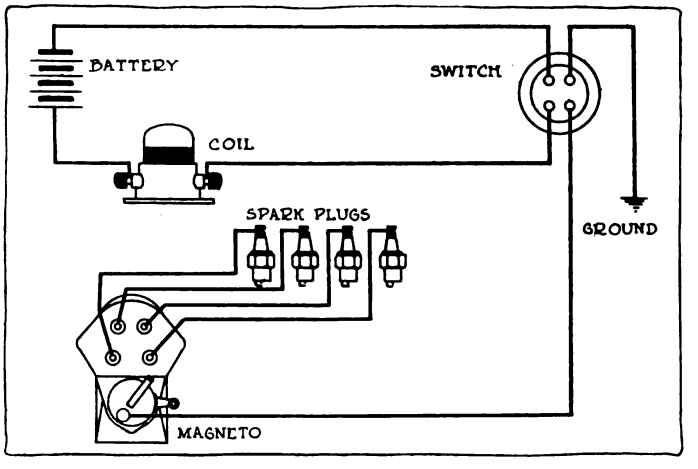

Fig. 6—Diagram of Bosch Duplex System with non-grounded battery

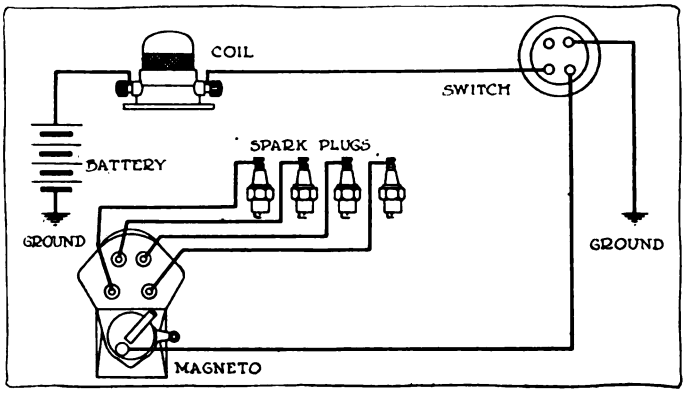

Fig. 7—Diagram of Bosch duplex system with grounded battery

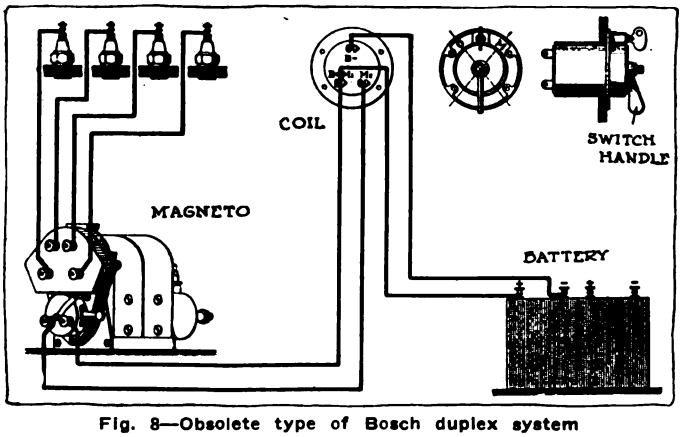

Fig. 8—Obsolete type of Bosch duplex system

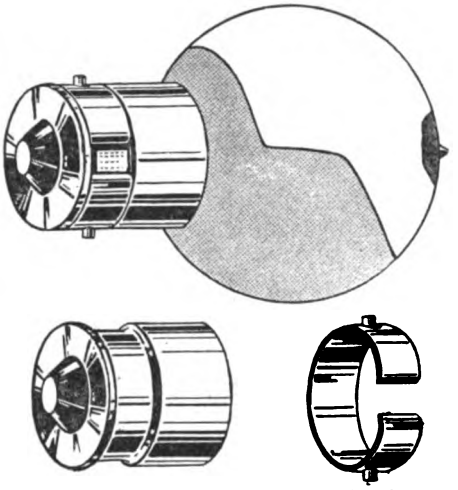
ACCESSORIES

Mac Kno-Glare Bulb

THE base used in the Mac Kno-Glare swivel bulb is the same size as the standard Ediswan base and will fit into any Ediswan socket of any make but the pins which hold the lamp in the socket are mounted on a separate ring fitting into a recessed portion of the lamp base. When locked in the socket the bulb may then be rotated to bring the portion of the bulb which has been treated with a semi-translucent compound to the bottom part of the reflector, it being unnecessary to change the socket position. When the current is turned on, the clear portion of the lamp bulb, being at the top part of the reflector, permits the light rays from the filament to strike the upper portion of the reflector which deflects them in an intensified form upon the roadway, while the treated portion of the bulb does away with the glaring rays and softens the light. These bulbs are made in all candlepowers and voltages in both single and double contact for all makes of cars. —A. Hall Berry, New York City.



Mac Kno-Glare swivel bulb, showing base

Defiance Welding Products

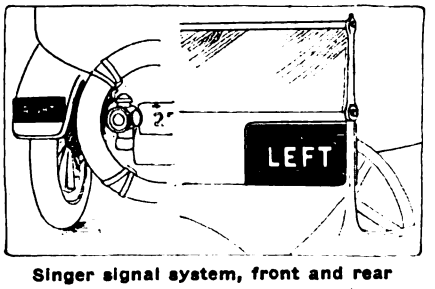
The Boko bucket is of canvas with a hoop rim and handle; it folds against the rim, lying flat. A tube leading from the bottom folds up against the side when not in use as a funnel. Capacity 2 gal. The makers state that they guarantee it to hold gasoline without leaking. The bucket lists at $1.25.

The makers of the Boko bucket also manufacture a folding steel-framed camp stool which, opened, measures 15 in. high and folds flat into a space 7½ by 10. The seat is of 10-oz. army duck and the weight 2 lbs. The stool sells for 75 cents each.—Defiance Welding Co., Defiance, Ohio.

Boko folding bucket, showing method of using

Singer Direction Signals

A signal which shows simultaneously on both the front and rear end of the car any proposed change in the direction or speed of travel is the latest in warning devices. By simply pressing an electric push button attached to the steering post or wheel these signs bear the words Right, Left, Circle, Stop or Slow. The signs are all operated by the one push button. The arrangement is so made that a single push of the thumb gives any desired signal, illuminates it if at night, and sounds the electric warning signal or bell, thereby making it of use for ladies driving electric or closed cars. The signals are inclosed in a small black enamel box, 8 by 6 in., and the letters are 1¾ in. high, a pure white on a black background. The manufacturers state that the letters can be read 150 ft. away. The signals are electrically operated and can be installed, according to the maker, in 15 min. The price has not yet been announced.—C. A. Singer, St. Louis, Mo.



Singer signal system, front and rear

Federal Handy Tire Tool

The Federal is a special tool for removing and replacing split demountable rims, and has ample leverage for doing the work without difficulty. The method of using it is clearly shown in the illustration. The tool folds into a small compass for stowing in the tool box. Price $2.—Federal Sales Co., South Bend, Ind.

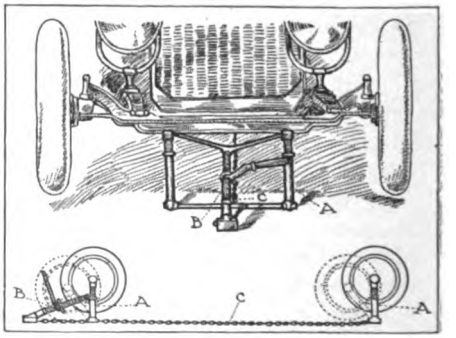
Federal handy tool for split rims

Waco Portable Garages

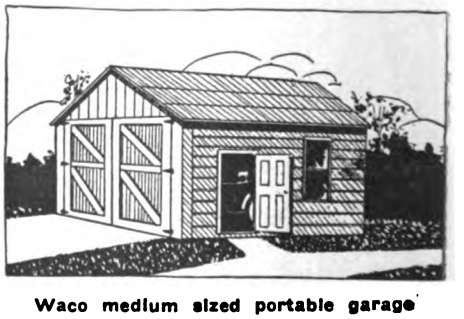
Waco garages are made in a number of styles and sizes, that illustrated herewith being suitable for any medium-sized car. The structure is 9 by 16 ft. of Georgia pine or steel sheeting with felt, rubberoid or imitation gravel roofing. The various parts are interchangeable as to position so that windows and doors may be arranged wherever desired. The standard outfit includes one double door, one single door and a window. Flooring is not furnished at the list price, which is $65 for the garage illustrated, but may be obtained at the rate of 10 cents per sq. ft. for cement, or 8 cents for wood. Other sizes range from the Ford type selling for $55 to a 16 by 18-ft. building for $120.—Wabash Automobile Co., Chicago, Ill.

Reading Four-Wheel Jack

This is a jack which permits the simultaneous jacking up of all four



Reading four-wheel car jack



Waco medium sized portable garage

wheels of a car. It consists of a pair of steel frames *A*, one for the front and the other for the rear axle; each frame carries two adjustable heads to pick up the axle. The frames are connected together by a heavy steel chain *C*, and one of the frames is connected with a screw jack *B* by a short chain. The car is run over the jack, the heads placed in position against the axles and the screw operated, which raises the whole car and holds it steadily with all wheels free and clear. The length of the chain and the height of the lifting heads are adjusted to suit the car on which the jack is used. The makers state that it is perfectly safe to run the motor and do any other work on the car with the jack under it. The weight of the jack is 65 lb. and the safe load is given as 6000 lb. Price, $20.—Reading Automobile Co., Reading, Pa.

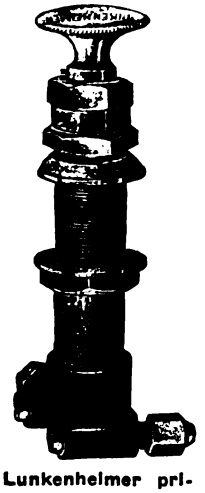
Cox Bumper for Cadillacs

A new Cox bumper has been put on the market especially for the 1916 Cadillac. This car differs from other models and makes in several ways and requires a special type bumper. As shown in the illustration, the bumper is attached by brackets which go over the spring horns and no additional holes need be drilled. The two bolts which hold the splasher and mudguard to the frame are replaced by two longer ones supplied by the manufacturers of the bumper. These bolts anchor the frame, mudguard, splasher and bracket securely. Where the bracket goes over the nose of the frame it is held by a special lock-nut which fastens on the regular shackle bolt which is supplied.

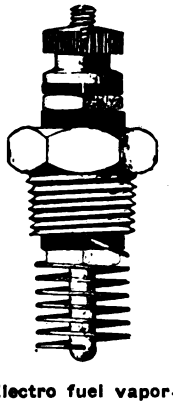
The bumpers are made in channel, diamond and round shapes. Each type is furnished in either nickel or black and the retail prices range from $6.50 to $10.—Cox Brass Mfg. Co., Albany, N. Y.

Hughes-Bull Valve Tool

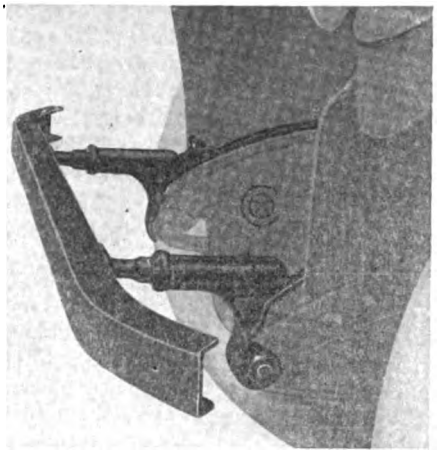
This tool trues both valve and seat in one operation, being of the milling cutter type and double, the seating tool being at the lower end and the cutter for the valve itself in its upper part. In operating it the tool is placed in the valve chamber, the lower cutter resting on the valve seat, the valve is then put in with the stem extending through the tool and down into the valve guide. The truing operation is effected by turning the tool by the driver at the top. The standard set sells for $5.50 and the Ford size for $5.—Hughes, Bull Co., Engineers, Detroit, Mich.



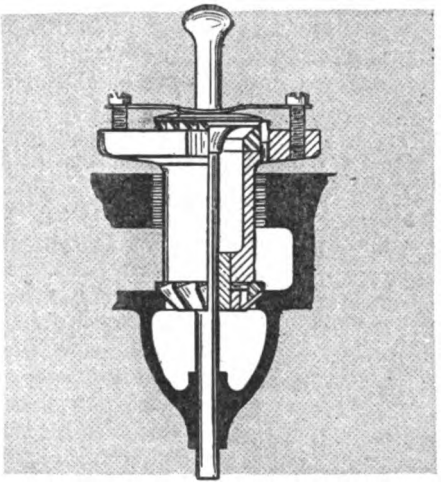
Lunkenheimer primer



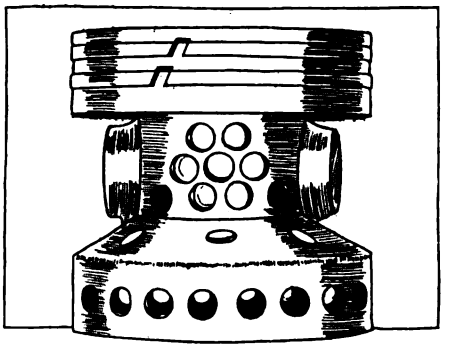
Electro fuel vaporizer



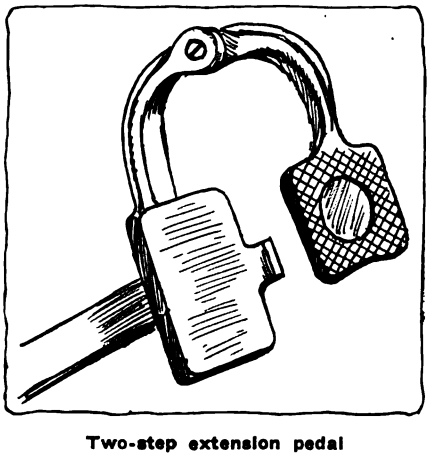
Cox special bumper for Cadillacs



Hughes-Bull valve-and-seat finishing tool



Zephyr extreme light-weight piston drilled for oil drainage and weight reduction



Two-step extension pedal

Zephyr Pistons

These pistons which are of the hourglass type are extremely light, the rings being in the upper part and the wristpin bosses in the center which is smaller in diameter than at the top and bottom. The central and lower parts are drilled for lightness and to promote lubrication.—Wridgway Co., Wilkes-Barre, Pa.

Two-Step Extension Pedals

In order to provide two pedal lengths for cars which are driven at times by people of one leg length and at other times by people of another length of leg, the two-step extension pedals have been brought out. As shown by the illustration, which is the type specially designed for Ford cars, both pedals are always in place and either can be employed. The Ford set sells for $2 per pedal fully nickel-plated.—Van Derbeck-Sayers-Murdock Co., New York City.

Lunkenheimer Primer

This primer occupies but little space, measuring ⅝ in. in diameter and 2⅝ in. in length, its operation is simple and convenient and it is compact and neat in appearance. The material used is a high-grade bronze which will not deteriorate under the chemical action of gasoline and the primer is quickly and easily attached. All necessary connections, such as tubing and unions, are furnished.—Lunkenheimer Co., Cincinnati, Ohio.

Electro Gas Vaporizer

In the Electro Gas Vaporizer a coil of resistance metal is screwed into the cylinder and is heated by an electric current, vaporizing the cold fuel with the object of making starting easy, especially in cold weather. A simple switch turns the current on and off. Current may be supplied from the starting battery or from a set of dry cells. Price $2.—Suburban Lighting & Gas Engine Co., Toledo, Ohio.

Blake Tube Flux

The makers state that the Blake flux for soldering is non-corrosive, and, when used for electrical work, has insulating qualities. It is put up in 2-oz. tubes with long aluminum spouts, so that the flux can be squeezed out on the work without danger of melting the spout. It sells for 20 cents per tube.—Blake Signal & Mfg. Co., Boston, Mass.

Angular Venturi in Edwards

New Carbureter Employs Compensating Dashpot—Combination Weather Adjustment and Starting Lever

THE Edwards carbureter which made its début in an economy run in Chicago recently, in which it made a record of 28.9 miles per gallon with a model D-45 Buick six carrying four people, as described in THE AUTOMOBILE recently, is manufactured by the National Carbureter Co., Chicago, Ill. While the showing of economy made on this test was an enviable one and the fact that the car developed a speed of 58 m.p.h. on a short stretch of country road without changing the adjustment of the carbureter is evidence that the mixture was not kept too lean, the new design of carbureter has other features which make it interesting.

Jet Enters Venturi at an Angle

This carbureter, which is the design of W. A. Edwards, is of the single-jet type in which the jet enters the venturi at an angle, as shown in the illustration. The use of the venturi is to increase the speed of flow. Increased acceleration is obtained by use of a piston operated by the air valve *A* which forces the fuel into the air stream around the needle valve. It is to this feature in part that the acceleration, of from standing start to 25 m.p.h. in 11 1/5 sec. through the gears and on high gear from 5 to 25 m.p.h. in 11 4/5 sec., on the recent Buick test may be credited.

In addition, there is a combination of weather adjustment and starting lever whose first movement regulates the vacuum in the instrument and the final movement seals the air valve to give a very rich starting mixture. To prevent the incoming air from blowing the gas coming from the venturi *V* across to one side of the manifold, the casting is made in a U-shape to provide a baffling wall *BW*, which directs the air upward over the mouth of the venturi. Any condensation is taken care of by a drain *H* which taps the mixing chamber and leads the liquid back into the venturi. This prevents loading when the throttle is opened quickly.

There is only one adjustment on the carbureter and that is the needle valve itself. In fact the company makes a point of the argument that no tools are needed in making adjustment or cleaning but all the work may be done with the fingers.

The Principle of Operation

To explain the principle of operation of the carbureter, it might be stated that it is constructed with the object of taking the fuel in at one point and breaking the particles of gasoline fine enough to be carried in suspension to the cylinders. The difficulty to be overcome in accomplishing this is that the gas particles on meeting the first obstruction or wall that will turn them in another direction have a tendency to revert to their original liquid form. By giving the gas great speed in the venturi *V* and then surrounding it with an outside wall of air which will hold it in suspension in the center, the Edwards design overcomes this.

It will be noticed that an inside needle *D* is used to meter the fuel. The purpose of this is to keep the gas from touching at any point. It is the belief of the designer that if an outside needle were used the fuel would cling to that needle and follow it by capillary attraction outside the zone of high speed so that when it left at the end of the needle it would leave in heavy drops. The needle is controlled by the air valve *A* by a control bar at the lower end of the air valve stem. The end of the bar is bifurcated and sets over a collar *C* on the metering pin or gasoline nozzle. The collar has a groove in it which allows a certain amount of play in the movement of the control bar as it in turn is moved by the air valve. If the metering pin were set to a rich idling mixture, the groove would permit the air valve to open and allow sufficient air to enter to reduce the rich mixture to the economical operating point.

Compensating Dashpot Used

At the bottom of the air valve stem will be noticed a dashpot *B* or compression chamber. This is used to compensate for the lack of the gasoline on the quick opening of the throttle. The moment that atmospheric pressure opens the air valve, that movement is transmitted to the dashpot piston which in turn creates a pressure in the dashpot chamber. This chamber has gasoline in it and the latter is drawn through passages *P* from the float chamber to the upper part of the compression chamber. This is to relieve the vacuum that ordinarily would be created on top of the chamber in the downward movement of the piston. A horizontal venturi passage *E* from the float chamber to the compression chamber is provided to allow a free movement of the gasoline in one direction but restricted in the other and at the same time to raise the compression at that point.

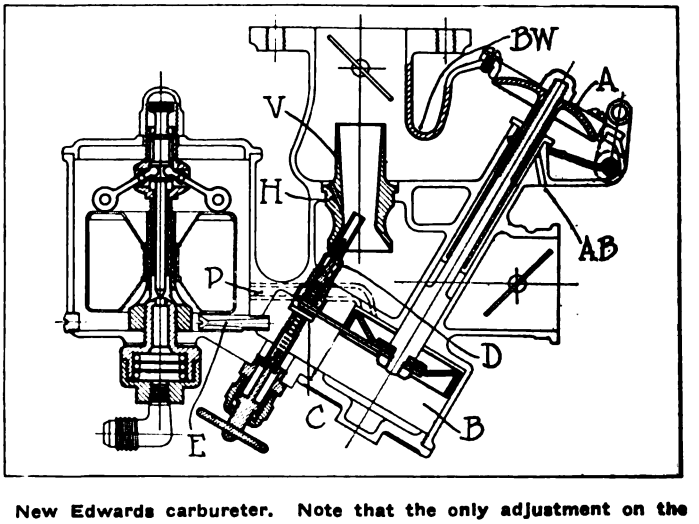
Heating the Incoming Air

The heated primary air passes around the throat of the venturi so that not only will the heat itself help to vaporize the liquid but the venturi also be kept hot. After it is warmed up, the hot air no longer is applied at that point as any heat added to the charge before its entry to the cylinder will be deducted from the final power output.

The cold weather adjustment is not a delicate one but instead of a highly sensitive needle to make adjustments with, the Edwards uses a spring tension which varies the vacuum in the body of the carbureter to draw more or less vapor from the nozzle as the condition demands. In starting in cold weather, the operator will pull up the weather adjustment to its limit which would not only raise the vacuum in the body of the carbureter but also would seal the air valve.

The needle valve has a beveled seat and is floating so that dirt would be unlikely and a twist of the valve releases any accumulating. The outside connections of the float needle permits the location of a leak in the float chamber. The metering pin is ball shaped so careless repairing does not put it out of commission.

To relieve any vacuum that might be caused along the air valve stem, this is open to the air through the hole *AB*.



New Edwards carbureter. Note that the only adjustment on the carbureter is that of the needle valve

$1,000

THE nearer it gets to the time of the national shows the clearer it becomes that one of the outstanding features of them will be the remarkable value offered by cars costing close to $1,000. There is a wonderful difference between the $1,000 car of 1916 and that of a year ago, almost, one might say, it is a totally different class of vehicle.

In 1914 a $1,000 car was a cheap car; it was around $1,500 that one began to find cars that were wholly good and not merely good for the money. To-day, most of the $1,000 class are thoroughly fine examples of engineering, of body construction, and of efficiency in the widest sense.

A year ago a man looking for a quality car without regard for the price would only rarely have been attracted by the engineering quality or the appearance and finish of any machine costing so very much less than $2,000. To-day there are several $1,000 cars which would arrest the attention of any show visitor unless he were seeking an essentially large vehicle. Perhaps this fact records the most remarkable achievement of the automobile industry to date. It is quite as remarkable as the value given in the really cheap cars which still look a little cheap, and it makes a strong appeal to that large class which prefers something small and thoroughly excellent for its limited amount of cash, to a larger and confessedly cheap article.

Aluminum Will Be Cheaper

TAKING a line right through the speech made by A. V. Davis, president of the Aluminum Co. of America, at Detroit, last week, it appears that aluminum will be a little cheaper within a few months, provided that the demand does not increase greatly in the meantime. That it will return to a more normal price only so soon as the war shall end, and importation recommence. But another thing, too, is obvious—namely, that after the war America will be able to turn out far more aluminum than ever before.

At present we are told the output is 80 per cent above normal. In the spring it will be more than double the average for the past five years. In three to five years' time it may be very much greater again. Add to this increase in home production the foreign exports of aluminum to this country, and it follows that the amount of aluminum available in 1918 or 1919 will be vastly greater than ever before in history. Mr. Davis refrained from prediction as to the price to be expected, but made it clear that water power legislation had a powerful influence on the cost of production. Since ore is plentiful and very cheap, it is to be hoped that power will be forthcoming soon, for it is hard to think of any application thereof which would be of greater benefit to the world in general than in providing large quantities of a metal which is ideal for very many purposes besides those of the automobile.

S. A. E. Sections Important

THE present year has seen the various local sections of the S. A. E. increased in number and fomented in activity. Not only are the meetings of the sections showing a better attendance, but they are obtaining papers which rank very highly. In Detroit and at Indianapolis this fall there have been discussions as keen as any in a general meeting, there has been an attendance of engineers equal almost to that on the summer meeting lake trip.

This is a splendid thing for the good of the industry, and the fact that the activity of the sections has grown gradually shows that it is a natural, healthy state of affairs which we now see. To a great extent the success of the section depends on the men who make its officers, but as the sections grow in strength this will change a little and the honorary officials will not be called upon for so great an amount of hard work in getting the men together at the meetings and in securing new members.

The reading of one good paper encourages the production of another, and as the basis of the S. A. E. is wide enough to cover a multitude of subjects, there is always a fresh angle for somebody to tackle. There are many commercial matters quite as important as the engineering subjects and signs are appearing which indicate these will obtain a growing amount of recognition. The section activities are showing non-technical members of the industry how far-reaching is the beneficial influence of the society.

17 Members in G. M. Board

No Action Taken on Common Dividend—Production and Sales Larger

NEW YORK CITY, Nov. 17—At the annual meeting of the stockholders of the General Motors Co. yesterday in Jersey City, the directorate was increased from fourteen to seventeen members. President C. W. Nash said regarding the affairs of the company that all the companies in the General Motors Co. are now for the first time since he has been associated with the company on a paying basis. From Aug. 1 to Nov. 11, the company's production was 12,250 cars in excess of a year ago, while the sales were 13,250 cars ahead of those in the same period of a year ago. The company has a large cash balance, notwithstanding that recently the total of $11,000,000 has been paid in dividends and retirement of notes.

No action was taken regarding a common dividend at the meeting yesterday. The matter was left until the next meeting.

The slate of directors agreed upon at the directors' meeting on Sept. 18 is as follows: Lammont Belin, director of the Aetna Explosives Co.; L. G. Kaufman, president of the Chatham & Phoenix National Bank; Pierre du Pont, S. F. Prior of the Union Metallic Cartridge and Remington Arms Co.; A. H. Wiggin, C. H. Sabin, J. A. Haskell, A. G. Bishop, E. W. Clark, W. C. Durant, H. J. McClement, C. S. Mott, C. W. Nash, Thomas Neal, J. J. Roskob, Albert Strauss and J. J. Storrow.

The old and new boards are compared as follows:

New Board	Old Board
E. W. Clark	E. W. Clark
J. H. McClement	J. H. McClement
Thomas Neal	Thomas Neal
C. S. Mott	C. S. Mott
C. W. Nash	C. W. Nash
J. J. Storrow	J. J. Storrow
Albert Strauss	Albert Strauss
W. C. Durant	W. C. Durant
Lammont Belin	Joseph Boyer
L. G. Kaufman	R. F. Herrick
Pierre du Pont	E. D. Metcalf

Gatlin Off for South Africa

DETROIT, MICH., Nov. 13—Guy G. Gatlin sailed Nov. 1 from London, where he will proceed to Cape Town, South Africa. He has been appointed South African sales manager of the export department of the Hupp Motor Car Co.

Lockhart Heads Wright Aeroplane

NEW YORK CITY, Nov. 15—Henry Lockhart, president of the Simplex Automobile Co., New Brunswick, N. J., was elected president of the Wright Aeroplane Co., Dayton, Ohio, which was recently purchased by a syndicate headed by W. B. Thompson. The company has increased its capital from $1,000,000 to $5,000,000. Mr. Lockhart sailed for England Friday in the interests of the company.

T. Frank Manville, president of the H. W. Johns-Manville Co., resigned as president of the Wright company because he found that he could not give sufficient time to the interests of the company. He remains, however, as a member of the executive committee and as a director.

Three More N. A. C. C. Members

NEW YORK CITY, Nov. 16—Three more companies have been admitted to membership in the National Automobile Chamber of Commerce, Inc. They are the Denby Motor Truck Co., Detroit, Mich., maker of Denby trucks; Grant Motor Co., Findlay, Ohio, Grant car; and Dort Motor Car Co., Flint, Mich., Dort car.

Vanderlip an S. K. F. Director

HARTFORD, CONN., Nov. 11—Frank A. Vanderlip, president of the National City Bank, has been elected a director of the S. K. F. Ball Bearing Co., this city, recently incorporated to take over the business of the S. K. F. Ball Bearing Co. of New York.

Besides Mr. Vanderlip, the board will consist of B. M. W. Hanson, vice-president of Pratt & Whitney, Hartford, Franklin B. Kirkbride of 7 Wall Street, A. Carlander and S. Winquist, directors of the Swedish S. K. F. Co., which is a large holder in the new American corporation, and B. G. Prytz, who will act as president.

Morrey V. P. of Hayes Wheel Co.

JACKSON, MICH., Nov 11—W. C. Morrey, manager of the timber department of the Hayes Wheel Co., has been promoted vice-president, while William C. Snyder and H. D. Hartley, Piqua, Ohio, have become members of the board of directors. The company's capital stock was recently increased to $1,000,000.

Sun Buys Plant in Elkhart

BUFFALO, N. Y., Nov. 15—The Sun Motor Car Co., this city, is preparing to move its plant to Elkhart, Ind. Preparatory to coming here the concern has purchased for $25,000 the plant of the Sterling Motor Car Co. The company will manufacture a light six-cylinder car and expects to begin operations about Jan. 1.

180,243 Cars in Ohio

COLUMBUS, OHIO, Nov. 13—According to a report recently issued by Registrar W. H. Walker, 180,243 automobiles were registered up to Nov. 10.

Reo 10-Mos. Surplus $3,661,802.20

$1,969,720.20 Over 1914—$2,390,951.60 Cash on Hand and in Banks

LANSING, MICH., Nov. 13—On Aug. 31 1915, at the end of ten months of its fiscal year, the Reo Motor Car Co. had $3,661,802.20 surplus or $1,969,720.20 more than at the end of its entire 1914 fiscal year. During the same period of ten months, the cash on hand or in banks totaled $2,390,951.60 as compared with $738,145 in 1914, meaning an increase in cash disponible of $1,652,806.60.

The assets total $7,373,995.99 while for twelve months in 1914 they totaled only $5,120,782, an increase of $2,253,213.99 in favor of the current year.

These assets include the cash item already referred to; notes and accounts receivable, less reserves, $582,176.46 instead of $684,184 in 1914; inventories, $1,957,708.74 as compared with $1,923,212 in the previous fiscal year. The capital assets are recorded for a total of $2,427,592.45 while in 1914 they totaled $1,765,989. Investments total $3,000 and deferred charges $12,565.74.

Among the liabilities, capital stock remains at $3,000,000; current liabilities total $712,192.79; accounts payable, $653,637.27 as compared with $368,407 in 1914; surplus $3,661,802.20.

Reo Truck Assets Gain $231,510.09 in 10 Months

LANSING, MICH., Nov. 13—During ten months of the fiscal year 1915, or up to Aug. 31, the balance sheet of the Reo Motor Truck Co. shows assets to be $1,409,251.09 or an increase of $231,510.09 over the twelve month's record of 1914.

The cash balance which was $266,242 in 1914 shows a total of $656,616.42 this year. Bills receivable totaled $191,435.95 against $73,027 in 1914. Inventory is recorded at $349,912.35 or $40,000 more than last year. The item of tools, machinery, etc., is credited with $102,884.51 as compared with $96,553 last year.

Among the liabilities the outstanding capital stock is unchanged at $937,500; bills payable total $200,179.67 instead of $142,479 last year; accrued pay roll totals $9,652.07 prepaid expenses, $6,488.61 and the surplus is shown to be $250,680.74 as compared with $91,062 last year.

Ferry Delion Tire Sales Manager

TRENTON, N. J., Nov. 11—C. C. Ferry has been appointed sales manager of the Delion Tire & Rubber Co., Trenton. Mr. Ferry will make his headquarters at the factory in Trenton.

New Abbott Six for Under $1,200

Continental Motor 3¼ by 4½ with Detachable Head—Seven-Passenger Body

DETROIT, MICH., Nov. 15—The Consolidated Car Co., maker of the Abbott-Detroit, will soon have ready for market a six-cylinder model to be known as the Six-44, and to sell at a price under $1,200. Although the complete details will not be available for about two weeks, it is known that the car will have a 3¼ by 4½ motor of Continental make. The six cylinders and the upper half of the crankcase are in one piece with head removable.

The car is to have a wheelbase of 122 in. and will seat seven. The shape of the body and its general lines are to be in accord with latest body ideas, it is said. Nearly straight, semi-elliptic springs are to be used all around, the rear pair being 57 in. long. The clutch is a dry disk type and the gearset three speed. A two-unit starting and lighting system will be fitted, the starting motor connecting through the Bendix drive. Battery ignition is to be used.

Disco Corp. Takes Co.

DETROIT, MICH., Nov. 16—*Special Telegram*—The Disco Electric Starter Co. has been taken over by the Disco Electric Starter Corp., just formed and capitalized at $250,000. The plant will be enlarged and its production facilities greatly increased.

The new officers of the company are: President, S. W. Elston; vice-president, J. F. Johnson; secretary-treasurer, Sol Meyer, and sales manager, Manzell Hackett.

Sterling Four at $550

NEW YORK CITY, Nov. 15—The Sterling Automobile Mfg. Co., Inc., this city, is bringing out a four-cylinder roadster to sell at $550, the price including two-unit electric starting and lighting system. The motor is a Sterling, water-cooled, having a bore of 2⅞ in. and a stroke of 4 in., is block-cast and has overhead valves. The company will put this car on the market shortly and it will be displayed at the New York show.

Ford Reduces Closed Car Prices

DETROIT, MICH., Nov. 16—The Ford Motor Co. has reduced prices on its sedan and coupelet. The sedan, which formerly was $975, is now $740, a reduction of $235. The body sells separately for $400. The coupelet is reduced from $750 to $590, a reduction of $160. This body sells for $250.

The runabout remains $390, the touring car $440 and the chassis $360. The sedan and coupelet are not of the detachable type. Each is a complete body in itself. Both fit the standard Ford chassis. Deliveries on this winter's cars are just beginning. All prices are f.o.b. Detroit.

Frank Briscoe Is Briscoe Manager

JACKSON, MICH., Nov 11—Frank Briscoe, brother of Benjamin Briscoe, president of the Briscoe Motor Co., has been appointed general manager, succeeding Horace De Lisser, who held that position and is vice-president of the company.

Evans Perfection Tire V-P

FRANKLIN, PA., Nov. 11—R. J. Evans, president and general manager of the Franklin Mfg. Co., has resigned to accept the vice-presidency of the Perfection Tire & Rubber Co., Fort Madison, Iowa, which was recently formed to build a heat-and-water-proof tire, guaranteed to give satisfactory service for 7000 miles without punctures or blowouts.

Yoke Is Maxwell District Supervisor

DETROIT, MICH., Nov. 10—John Yoke, who was sales supervisor of zone No. 5 of the Maxwell Motor Co., has been promoted district supervisor of sales and will have charge of all the field men and the twelve field headquarters which are maintained by the Maxwell company as wholesale and contracting centers.

Hinckley with Connecticut

CHICAGO, ILL., Nov. 12—P. P. Hinckley of Chicago has joined the sales force of the Connecticut Telephone & Electric Co. and will handle the jobbing trade East of Chicago. The jobbing connections in Chicago and the West will be managed by J. W. Fulton with offices at 1100 Karpen Bldg., Chicago.

Hanson with Service Truck

WABASH, IND., Nov. 13—A. B. Hanson, until recently manager of service department of the Chalmers Motor Co., Detroit, Mich., is now general manager of the Service Motor Truck Co. The plant of the Service company is now being doubled.

W. McK. White Leaves Esterline

INDIANAPOLIS, IND., Nov. 13—W. McK. White, sales manager of the Esterline Co., this city, has resigned. Mr. White formerly was associate editor of THE AUTOMOBILE, and gave up that work to become advertising manager of the Premier Motor Mfg. Co., resigned that position to handle the advertising of the Marion Motor Car Co. and then entered the Esterline company as sales manager some two years since.

18,000 Chalmers 6-30's in 6 Months

600 Dealers in Convention at Factory Hear Big Production Plans

DETROIT, MICH., Nov. 15—The annual convention of the Chalmers Motor Co.'s dealers opened at the new auditorium of the plant at 10 a. m. to-day. President Hugh Chalmers made the address of welcome.

At this first meeting of the dealers with the officials of the company they were told that it is the intention of the Chalmers company to build, during the next six months, 18,000 of the new Chalmers Six-30 cars, a new model described on pages 925-927, which is to sell at $1,050, or lower than any Chalmers car previously produced. It was stated by officials that dealers have contracted for $22,000,000 worth of the new models.

Out-of-town dealers have been coming in since Saturday and it is expected that fully 600 will be seated at the dinner, which will be served to-night in the convention hall of the Hotel Ponchartrain. At this hotel 238 Chalmers dealers were seated at the breakfast tables this morning. A large number are registered at other hotels. At the Ponchartrain it was stated that the number of dealers there is the largest from one manufacturer which the hotel had to take care of during the last four or five years.

During the morning after the dealers had placed their orders, a parade of some 300 Chalmers cars was held. To-day's morning session was merely one of welcome.

Tuesday, Nov. 16, there will be business sessions throughout the day, and inspection of the plant. In the evening a dinner and cabaret show will be given at the Hotel Statler. Wednesday will be featured by a detailed discussion of the new Chalmers Six-30 by Chief Engineer C. C. Hinkley. The afternoon will be taken up by a business session and the evening will see the close of the convention, the final event being a banquet to be tendered the dealers at the Detroit Athletic Club.

Bell Monarch Sales Manager

DETROIT, MICH., Nov. 12—J. L. Bell, who has been service manager of the Monarch Motor Car Co., has been promoted to sales manager of the company. Mr. Bell has been connected with the automobile business since 1909, starting with the Staver Carriage Co., Chicago, and later being with Abbott and R-C-H. The Monarch company has opened a branch at 270 Jefferson Avenue, under Mr. Bell's management.

Big Truck Orders Keep United Kingdom Our Best Customer—Export Statistics

In September Great Britain Took 2650 American Cars and Trucks Worth $3,119,806—France's Purchases Jump from 1044 to 4885 for Nine Months—Other Increases

WASHINGTON, D. C., Nov. 16—In addition to the gross figures of exports of automobiles for September and the nine months ended September, together with the figures for the corresponding periods of last year, previously published in THE AUTOMOBILE, herewith are presented the export figures for the various countries that have participated in the automobile trade of this country during those periods.

United Kingdom Gains

The big feature of the export trade is the tremendous increase in the exports to the United Kingdom, and while the figures do not show it, the increase is undoubtedly due to the orders for trucks. In September last Great Britain imported 2650 cars, valued at $3,119,806, as against 136 cars, valued at $154,763, in September a year ago. During the nine months ended September, these exports increased from 5130 cars, valued at $4,281,026, in 1914, to 19,434 cars, valued at $28,648,749, in 1915.

There were no exports of automobiles to France in September, 1914, while in September last 421 cars, valued at $916,830 were exported to that country. During the nine months' period these exports rose from 1044 cars, valued at $625,636, in 1914, to 4885 cars, valued at $12,126,628, in 1915.

Coming back to this side of the ocean the figures show that Canada imported 260 cars, valued at $433,620, in September, 1914, while in September last the number increased to 367 cars, but the value thereof was only $278,382. During the nine months of 1914 the number of cars shipped across the Northern border was 3,854, valued at $4,881,062, while during the nine months of this year the number was 5049, but the value was only $3,951,585.

The West Indies and Bermuda are rapidly becoming good customers for American-built motor cars. In September a year ago forty-two cars, valued at $37,240 were shipped to those islands, while in September last the number was 286 and the value $194,832. During the nine months' period the number of cars shipped there increased from 394, valued at $342,550, in 1914, to 2385 cars, valued at $1,305,005, in 1915.

Increase to South America

That American car manufacturers are reaching out for South American trade is indicated by the fact that during September, 1914, there were only twenty-four cars, valued at $19,735, shipped to those countries, while during September last the number was 595 and the value, $273,449. Even greater gains are shown in the figures for the nine months' period, the number for 1914 being 915 cars, valued at $742,262, while in 1915 the number was 2081, and the value $1,066,486.

British Oceania is also taking a liking for American cars, 219 of them, valued at $155,597, being shipped there in September a year ago, while in September last the number increased to 387 and the value to $312,856.

A fine showing is also being made in the exportations to Asia and other Oceanic countries, 387 cars, valued at $312,856 having been shipped there in September last, as against thirty-nine cars, valued at $38,975, exported there in September a year ago. The complete table is given herewith.

Walker Co. Goes to Cleveland

DETROIT, MICH., Nov. 13—The J. H. Walker Co. automobile parts manufacturer who started in business here in 1910 and who has been making many of the parts for the Chandler Motor Car Co., Cleveland, will locate in the Ohio city about Dec. 1. A factory building having 45,000 sq. ft. of floorspace is now almost ready for occupany. Another building will be erected within a short time. New machinery and equipment valued at over $100,000 will be installed.

Joliet Tractor at $865

JOLIET, ILL., Nov. 12—The Joliet Tractor Co., Joliet, Ill., has brought out a farm tractor, which it has christened the Bates Steel Mule. One of the features of this tractor is the oscillating crawler, which acts very much like a human being walking on the ball of the foot. The load-pulling on the compound lever hitch, combined with the downward force of the springs, have a tendency to pull the front end of the crawler into the ground. Offsetting this action is the weight of

the tractor body on the hinge in the rear of the crawler. The combination of these two forces holds the crawler evenly to the ground. Its entire length gives it broad traction and flexible gripping as well.

The engine is a four-cylinder Waukasha, heavy-duty tractor type, with a bore of 4¼ in. and a stroke of 5¾ in. Lubrication is by the pump and splash, constant-level system and cooling is obtained by centrifugal pump. A high-tension magneto is used.

Two speeds forward, 2 1-3 and 3½ m.p.h., are offered, and the reverse is 2 m.p.h. The weight of the tractor is 4800 lb.; the ground pressure, 4½ lb. to the square inch.

Willys-Overland, Ltd., Formed in Canada—$6,000,000 Capital

TOLEDO, OHIO, Nov. 17—The Willys-Overland, Ltd., has been formed in Canada with a capital of $6,000,000 and head offices in Toronto. J. N. Willys, head of the Willys-Overland Co., this city, will be president of the new company. T. A. Russell, at present vice-president of the Russell Motor Car Co., of Canada, will be vice-president.

Five of the directors of the Willys-Overland Co. of Toledo, will be directors of the new company; these are J. N. Willys, H. T. Dunn, Walter Stewart, Harry Shepler, C. A. Earl, T. A. Russell and Lloyd Harris of Toronto, and two of the other Canadian stockholders will also be on the board.

This new company will take over the complete automobile business of the Russell Motor Car Co., and all of the business in Canada of the Willys-Overland Co.

Although the Canadian company will be independent of the parent company and will be conducted entirely independent as a Canadian corporation, it will have the advantage of the advice and engineering skill of the Willys-Overland Co. organization. The plan is to undertake in Canada the actual manufacture of both Overland and Willys-Knight automobiles. For this purpose the plant of the Russell Motor Car Co. of Toronto has already been acquired and this quickly will be enlarged to permit quantity production.

—

Racine Rubber Adds

RACINE, WIS., Nov. 13—The Racine Rubber Co., this city, has broken ground for a large addition to its plant at Racine Junction, established about four years ago. The building will be three stories high, of steel, brick and concrete, and with equipment will cost in excess of $100,000. The addition will be used for the mill room and crude rubber storage. It is to be ready for occupancy on Feb. 1, at which time the company will add more than 100 men to the payroll, making a total of 750 operatives.

Peerless Eight at $1,890

—

New 2-Ton Truck Is Under Way—Co. Will Maintain Corporate Existence

CLEVELAND, OHIO, Nov. 15—The Peerless Motor Car Co., a majority of the stock of which was recently acquired by the Peerless Truck & Motor Corp., and which has also secured control of the General Vehicle Co., will continue as it has in the past maintaining a separate corporate existence. It will manufacture the eight-cylinder Peerless car, for $1,890, deliveries to begin in December and will also manufacture a regular line of Peerless trucks, to which a new 2-tonner will soon be added. The present executive force, sales, and factory organization will be continued without change.

The Peerless Motor Car Co., will be represented on the board of the Peerless Truck & Motor Corp., by L. H. Kittredge, president of the Peerless Motor Car Co., B. G. Tremaine, and F. S. Terry, all of the Peerless company.

The Peerless Truck & Motor Corp. reports consolidated balance sheet of its subsidiaries, the Peerless Motor Car Co. and General Vehicle Co., Inc., as of Sept. 30, 1915, after giving effect to adjustment incident to the acquisition of stocks as in the accompanying table.

—

Transport Is Latest Tractor

NEW YORK CITY, Nov. 3—The Transport tractor is the latest addition to the roster of American commercial vehicles. It is produced in one 5-ton model by the Transport Tractor Co., Long Island City, N. Y. The tractor attains a very short wheelbase by placing the unit power plant between the seats, and is worm-driven. It has a new type of trailer connection for semi-trailers, consisting of a dome and cup, the dome surmounted by the king bolt and the cup carrying the cup and king bolt guide. It is designed to turn in a circle of 25 ft. diameter, and is priced at $2,500.

Consolidated Balance Sheet of Peerless Truck Motor Corp.

ASSETS

Patents, franchises and goodwill ($5,000,000 of this represented by common stock of General Vehicle Co., Inc.)		$5,100,000.00

		2,068,032.70
		$14,362,726.64

In the acquisition of the capital stock of the Peerless M. C. Co. and the General Vehicle Co., Inc., there have been issued by the Peerless Truck and Motor Corp.:

Capital stock, 200,000 shares, par value $50 (Authorized issue 400,000 shares.)	$10,000,000
Ten-year 6% convertible gold notes	5,000,000
There has been deposited with the trustee, to retire the balance of the outstanding bonds of the Peerless M. C. Co	600,000
Also there has been deposited with the trustee to acquire the balance of the outstanding shares of the Peerless M. C. Co	637,695
Cash in bank	292,500

The company has no liabilities except the 6% convertible gold notes above stated

S. A. E. Forms Penn. Section

Headquarters and Membership Problems Solved—Engineers' Club to Co-operate

PHILADELPHIA, PA., Nov. 11—At a meeting held here last night, the movement which has been on foot for some time, to organize a local section of the Society of Automobile Engineers has finally borne fruit. A new section, subject to the approval of the council of the parent body has been created under the name of the Pennsylvania Section.

There were about fifty in attendance at the meeting and the dinner which preceded it, out of which about half were members of the S. A. E. and the remainder were members of the Electric Vehicle Association and others who intend to become affiliated with the new section. The unanimity of opinion that the section should be formed and the enthusiasm which marked the initiation of the new organization give promise of a successful and rising branch of the parent organization.

E. S. Foljambe who has been one of the fathers of the movement, acted as toastmaster at the dinner and afterwards as temporary chairman. In speaking of the reason for the failure of the previous attempt, some years ago, to maintain a section of the S. A. E. in Philadelphia, Mr. Foljambe pointed out that the two main causes for lack of success have now been removed and there remains no apparent reason why the present undertaking should not succeed. The two causes referred to were the lack of a permanent headquarters and the former limitations on section membership which rendered it impossible constitutionally to have enough prospective members to draw upon.

Vote Was Unanimous

After stating the purposes of the gathering and dwelling upon the desirability of having a section of the society in Philadelphia, Mr. Foljambe turned the meeting over to Coker F. Clarkson, general manager of the S. A. E. With but little preliminary discussion, B. B. Bachman, of the Autocar Co., moved that it be considered the sense of the meeting that a section of the society be formed with its headquarters in Philadelphia. This was carried unanimously.

The next point which came up for discussion was as to the proposed name of the new section. The name Keystone was suggested by some as having a broad meaning and at the same time giving an idea to the locality. Others wanted the name Philadelphia section, but Pennsylvania was finally adopted. A temporary nominating committee for the purpose of choosing temporary officers was then named by Mr. Clarkson and while they debated this matter the question of a suggested meeting program was brought up.

K. W. Zimmerschied, chairman of the standards committee of the S. A. E., stated that he believed it would be a mistake to have too many meetings in the beginning as they would be apt to lack the importance which would attach to a shorter but more carefully thought-out program. The importance of giving the members of the section something to do he stated as another successful method of promoting interest. Mr. Zimmerschied dwelt on the importance of carefully selecting the officers of the section as the success of the organization depends largely on the efforts of the chairman and secretary. Coming to the matter of standards he went on to state an illustration of the importance of this work to the country. This country is going to manufacture hundreds of millions of dollars worth of ammunition, he said, but of what value will it all be if it is not standardized? This work of standardization is one in which the S. A. E. can be of valuable assistance.

Army and Navy Co-operation

Louis S. Clarke, vice-president of the Autocar Co., brought up the matter of encouraging army and navy officers to take part in the activities of the section. He pointed out that the appropriations of Congress for military automobiles will be enormous and that if this is the case, naturally the officers of both branches of the service will take an immense interest in a field which will undoubtedly claim such a large share of the appropriations. Mr. Clarke's views met with the approval of a great many of those present who spoke endorsing his sentiments.

Temporary Officers Elected

The temporary officers appointed by the nominating committee are E. S. Foljambe, Chairman; B. B. Bachman, secretary and Tinius Y. Olsen, treasurer. An application will be made to the parent organization for a section charter in the near future.

In discussing the manner in which the difficulties formerly encountered were solved it was brought out that the Engineers' Club of Philadelphia, which acts in co-operation with most of the local branches of the national engineering societies, has extended the use of the meeting room of the club to the new organization. Space for announcements has been given in the club bulletin and the members attending the meetings will have house privileges for the night of the meeting. In addition, the extensive library of the club has been put at their disposal.

The other difficulty, that of having but a small S. A. E. membership to draw upon, has been removed by the possibility of having section affiliates. The constitution of the S. A. E. now permits sections to have affiliate members who are not members of the S. A. E. These affiliates are allowed to attend the meetings and enter into the discussions but are not entitled to a vote. The large field of this class of membership in the Philadelphia territory opens up great possibilities for extensive membership.

Many Prospective Members

The section will embrace all of Pennsylvania and will accept members from New Jersey. Since the outbreak of hostilities abroad many steel and other manufacturing companies are engaged in making trucks, included among which are the Midvale Steel and Ordinance Co. and the Baldwin Locomotive Works, in addition to a number of others. Not only these people will be induced to become members but the engineering student body at the University of Pennsylvania will be asked, by reason of the fact that many, upon their graduation, will take up the automobile industry as their vocation.

At the close of the meeting E. R. Whitney, engineer of the Commercial Truck Co. of America, delivered an address on the use of electric trucks in difficult installations. The lecture was illustrated by stereopticon views of the different installations. Those who registered were as follows:

*Coker F. Clarkson, S. A. E., New York City.
*Karl W. Zimmerschied, General Motors Co., Detroit, Mich.
*Frank E. Whitney, Commercial Truck Co., Philadelphia, Pa.
W. A. Manwaring, 1208 N. Thirty-first St., Philadelphia, Pa.
E. J. Hancock, Curtis Publishing Co., Philadelphia, Pa.
W. H. Metcalf, 11 N. Twenty-first Street, Philadelphia, Pa.
W. H. Patton, 1828 Market St., Philadelphia, Pa.
H. A. Koockogey, Tenth and Chestnut Sts., Philadelphia, Pa.
*W. W. Norton, Autocar Co., Ardmore, Pa.
A. H. Burns, 305 S. Broad St., Philadelphia, Pa.
*E. R. Whitney, Commercial Truck Co., Philadelphia, Pa.
*R. B. Daggett, Commercial Truck Co., Philadelphia, Pa.
*B. B. Bachman, The Autocar Co., Ardmore, Pa.
S. M. Wilson, The J. G. Brill Co., Philadelphia, Pa.
M. J. Oswald, The J. G. Brill Co., Philadelphia, Pa.
*Wm. H. Palmer, Jr., Electric Storage Battery Co., Philadelphia, Pa.
*Frank Beemer, Pressed Steel Mfg. Co., Philadelphia, Pa.
William Reiter, Jr., Gibney Tire & Rubber Co., Philadelphia, Pa.
Walter H. Hart, Standard Roller Bearing Co., Philadelphia, Pa.
Geo. T. Gwilliam, 1304 Arch St. and 57 Broadway, New York City.
Frank H. Schoenfus, Standard Roller Bearing Co., Philadelphia, Pa.
Harold Goodwin, Jr., Philadelphia Electric Co., Philadelphia, Pa.
*Edward L. Clark, 825 N. Twenty-seventh St., Philadelphia, Pa.
*A. B. Cumner, 553 W. Twenty-third St., New York City.
*Albert G. Suttill, James Boyd & Bro., Inc., Philadelphia, Pa.
*E. S. Foljambe, Chilton Co., Forty-ninth and Market Sts., Philadelphia, Pa.
*Chas. E. Duryea, 3400 N. Seventeenth St., Philadelphia, Pa.
*Louis S. Clarke, Ardmore, Pa.
*E. S. Fretz, Pottstown, Pa.

*John S. Clarke, Ardmore, Pa.
D. Robert Yarnall, Chestnut Hill, Pa.
*Edward Dixon, Crowther Motor Co., Philadelphia, Pa.
Joseph D. Israel, 1000 Chestnut St., Philadelphia, Pa.
M. G. Lloyd, Chicago, Ill.
R. Louis Lloyd, 1000 Chestnut St., Philadelphia, Pa.
H. Wickland, The Hess-Bright Mfg. Co., Philadelphia, Pa.
*Herbert L. Towle, 214 S. 12th St., Philadelphia, Pa.
H. R. Doughty, The Hess-Bright Mfg. Co., Philadelphia, Pa.
*J. Edward Schipper, *The Automobile*, 239 W. 39th St., New York City.
H. N. Purdy, Edison Laboratory, Orange, N. J.
*H. E. Figgie, The Perfection Spring Co., Cleveland, Ohio.
*N. B. Pope, *Automobile Topics*, New York City.
*A. C. Bergman, Perfection Spring Co., New York City.

Three Additions for Hydraulic Pressed Steel Co.

CLEVELAND, OHIO, Nov. 11—The Hydraulic Pressed Steel Co. will build three plant additions costing approximately $50,000 at its factory at 3152 East Sixty-first Street. Two of the additions will be inclosed in glass. One will be 360 by 70 ft., and the other 200 by 80 ft., costing about $21,000 and $17,000 respectively. The third structure will be built of brick and steel covering a ground space of 60 by 120 ft. All are to be one story high.

—

1000 Briscoes to Be Made in Canada

BROCKVILLE, ONT., Nov. 12—T. J. Storey of Brockville, vice-president of Carriage Factories, Ltd., who was in Montreal yesterday, announces that within two or three weeks the Canadian Briscoe Co., a new subsidiary of Carriage Factories, will be turning out four and eight-cylinder medium priced automobiles, and that before the end of the year the company figures on placing on the market at least 1000 of these cars. The company will assemble the parts at Brockville, where the plant of the old Acme Automobile Co. has been taken over, and Carriage Factories will participate in portions of the manufacturing end. The cars to be placed on the market will be identical with the American Briscoe output, which will supply such portions of the car as are not made in Canada.

—

Fickling to Add 25,000 Sq. Ft.

LONG ISLAND CITY, N. Y., Nov. 13—The Fickling Enameling Corp., this city, is enlarging its plant by the addition of 25,000 sq. ft. to accommodate its assembling plant, and the wood-working, metal-stamping and upholstery departments, to take care of several large contracts recently received from manufacturers.

Maxwell to Build 500 Cars a Day

—

Extensive Additions Planned for All Plants—Assembly Building Nearly Completed

DETROIT, MICH., Nov. 13.—At all the Maxwell plants in Detroit, Newcastle, Ind., and Dayton, Ohio, extensive enlargement and expansion work has been started, the Maxwell Motor Co. contemplating increasing its daily production, which now averages 250 cars or better, to 500.

The biggest addition is being put up at the Oakland Avenue plant, here in Detroit, which will consist of a one-story building 860 by 130 ft., to be devoted exclusively to assembly purpose. This structure will cover about 4 acres of ground. The Maxwell company owns 50 acres of ground on Oakland Avenue and 12 acres are covered with buildings.

This new assembly building is to be completed within eighty days. Along its length will run two parallel moving platforms, similar to the one on which the company's product is now put together. It was designed by Production Manager Charles Adams, in co-operation with President Walter E. Flanders, for a daily output of 160 cars, but has been turning out more than 250 a day. The Maxwell output record for one day is now 286 cars.

The present platform will form one of the pair to be in the new building. The room vacated will be used in the manufacture of part of the increased number of units which the doubled assembly capacity will make possible.

The property adjoining the Maxwell plant and land on Oakland Avenue and which is occupied by the Gray Motor Co., is controlled by the Maxwell company, and a large part of the main building is operated as a motor factory for the Maxwell.

—

Walker-Weiss Gets Martin Plant

FLINT, MICH., Nov. 10—The Walker-Weiss Axle Co. has been advised that its bid for the plant of the H. J. Martin Forging Co., Indianapolis, has been accepted by Judge Clifford, of the superior court, of that city. The Indiana concern has been in the hands of a receiver since last January.

For some time the Walker company has contemplated enlarging its plant, but while it would have been easy to put up new buildings, it was found practically impossible to arrange for the immediate delivery of the machinery necessary for a drop forging concern. Therefore a bid was made for the Indianapolis plant, which has fifteen steam hammers with full equipment for heat treating and much other good material and machinery.

George Desautels, who has been connected with the drop forging business in the United States for the last sixteen years and is vice-president of the American Drop Forge Association, has been appointed general manager of the Walker-Weiss Axle Co.'s Indianapolis drop forge plant.

The Indianapolis plant of the Walker-Weiss Axle Co. will be under the management of Robert I. Gale, until recently purchasing agent for the Keeler Brass Co., Grand Rapids.

—

3000 Marion and Imperial Cars Planned

JACKSON, MICH., Nov. 10—According to President J. I. Handley of the Mutual Motors Co. there will be 3000 Marion and Imperial cars made for the season 1916. The entire output has been practically contracted for as the result of a recent business campaign in Texas and the East.

—

Efficiency Oil Co. Buys Plant

ST. LOUIS, MO., Nov. 13—The Efficiency Oil Corp. has purchased the plant formerly occupied by the Shiras-Chassing Fixture Co., on Kienlen Avenue, in Wellston. The building, which is a one-story structure, contains an acre and a half of floorspace. The company expects to occupy the new building before Dec. 1. The old plant of the company at Manchester Avenue and King's Highway Boulevard will be discontinued at the expiration of the lease the end of this year. The new building contains about ten times the old plant's floorspace.

—

Yale & Towne Increase Wages 10 per Cent

STAMFORD, CONN., Nov. 11—A general increase of 10 per cent in wages was announced by the Yale & Towne Co. It affects 4600 employees, and means an increase in the company's wage outlay of about $300,000 per annum.

—

Bijur Machinists Return to Work

HOBOKEN, N. J., Nov. 13—The strike of 200 machinists in the plant of the Bijur Motor Lighting Co., this city, has been settled. The strikers received a 50-hr. week, and a 5 per cent advance in wages.

—

Springfield Body Strike Settled

SPRINGFIELD, MASS., Nov. 11—The strike of 400 employees of the Springfield Metal Body Co., this city, on Nov. 1, who demanded an 8-hr. day and recognition of the union, has been settled.

—

Joy on Aero Club Board

DETROIT, MICH., Nov. 12—President Henry B. Joy, of the Packard Motor Car Co., has been elected a member of the board of governors of the Aero Club of America.

Hyatt Capital Now $6,000,000

Increase from $400,000 Rendered Necessary by Enlargement of Plants

NEWARK, N. J., Nov. 13—The Hyatt Roller Bearing Co., this city, will increase its capital stock from $400,000, its present capital, to $6,000,000. This increase has been made necessary by extensions to the factory both in the manner of new buildings and added equipment. Four new buildings are under construction, as follows: One building 90 by 115 ft. eight stories high, which is nearly completed; one building, 75 by 200, eight stories; one building, 125 by 200, one story; and one building, 75 by 200, eight stories. Construction work is just beginning on the last three buildings. These buildings will double the capacity of the Hyatt factory, which has been entirely devoted to the manufacture of roller bearings for automobile and other uses. These bearings are manufactured entirely for domestic sales. The present $400,000 stock is all common, and the new capitalization of $6,000,000 is common. It is all held privately and the stock is not listed or for sale.

—

Maxwell Offers First Preferred

NEW YORK CITY, Nov. 16—Holders of the three classes of Maxwell Motor stock of record Monday are offered the privilege of subscribing to first preferred stock of the company at par, to the extent of 5 per cent of their holdings. This step is taken in order to comply with legal requirements.

Under the plan recently announced for the funding of the accumulated 14¼ per cent back dividends on the first preferred stock, warrants will be issued to the extent of the 14¼ per cent, and will be convertible into first preferred stock at par. The amount of first preferred stock required for the future conversion of dividend warrants is $1,749,804, of which $720,667, represented by first preferred stock trust certificates now in the treasury, is already available, leaving a balance of $1,029,136 to be provided through the increase in the present amount of first preferred.

—

U. S. L. Gets Working Cash Capital of $500,000

NEW YORK CITY, Nov. 13—The United States Light & Heating Corp., through the purchase of 50,000 shares of its treasury stock by Slattery & Co., local brokers, gets a working cash capital fund of about $500,000. This amount includes previous amounts released and surplus cash turned over by the stockholders' protective committee. The company also has a substantial amount of common and preferred stock, still in the treasury. Beyond cash on hand, the other working assets of inventories and accounts receivable total several hundred thousand dollars. There are no liabilities beyond current trade accounts, all of which are now discounted in cash, saving thereby an amount in excess of the interest on the $500,000 bonds outstanding.

—

Market Prices Advance

NEW YORK CITY, Nov. 16—Market prices in general were higher last week. Crude rubber, metals, and oil prices saw large advances. The reported closing of the Suez Canal was reflected in the rising in prices. Crude rubber, both here and in London, went up. Fine Up-River Para closed on Monday at 64 cents, 5 cents higher than the opening the previous Tuesday. It was contended by some that the effect upon the trade was not likely to be serious, as it would result merely in a delay of a few weeks in arrivals of rubber from the Far East. The tin market, as a result of the report, was severely upset. Spot tin advanced $7.75 a ton, closing at $44.00 on Monday.

Oil prices in Kansas reached the $1 mark yesterday, when the price was advanced from 90 cents a barrel. Pennsylvania crude is now $1.90 a barrel. Gasoline prices throughout the country went up again last week. The rise in prices was the strongest demonstration the market has yet given of improvement in oil conditions which set in during August last.

Copper advanced yesterday to 18¾ cents a pound. This metal is growing scarce, and since prompt deliveries are being demanded, the result has been an advance in the quotations.

Lead advanced to $5.25 per 100 lb. yesterday. The demand for lead has been very active, and consumers were reported to be running very low on stocks.

—

McNaull Tire Co. Increases Capital $2,225,000

TOLEDO, OHIO, Nov. 11—The McNaull Tire Co. has been incorporated with a capital of $2,500,000. The new company is to succeed the McNaull Auto Tire Co., which operates a manufacturing plant on the East Side.

The present capitalization of the McNaull Auto Tire Co. is $275,000. Under the reorganization the capital of $2,500,000 will be divided into $1,000,000 preferred and $1,500,000 common stock.

The plant will be enlarged by the reorganized company and employment given to 1000 more men.

W. D. McNaull was elected president; M. W. McNaull, vice-president, and A. B. Laskey, secretary, at a meeting of the McNaull Tire Co., held Nov. 12.

As the McNaull Tire Co. succeeds the McNaull Auto Tire Co., the directors of the old company will serve as a provisional board, representing Eastern men who have agreed to finance the new concern. W. D. McNaull was president of the old concern.

—

Overland to Redeem Preferred

NEW YORK CITY, Nov. 12—The Willys-Overland Co. has given notice that it has decided to redeem the whole of its preferred stock at 110 per cent of par, plus accrued dividends. Each holder is requested to present his certificate of stock at the office of William Salomen & Co., 25 Broad Street, this city, on Jan. 13 next, when he will receive payment. After that date dividends will cease on the stock.

—

Bourne Truck to Use Master

DETROIT, MICH., Nov. 13—The Master Carbureter Corp. announces that the Atlantic Refining Co., Philadelphia, Pa., which is a subsidiary organization of the Standard Oil Co., has contracted to use Master carbureters as standard equipment on the Bourne truck, which the company is bringing out.

of the United States and Canada had only 26,239 idle cars on hand. This compares with 78,299 a month ago and with 170,096 on Nov. 1, 1914. Railroad men say that there may be an actual shortage seen.

PHILADELPHIA, PA., Nov. 12—The Pennsylvania Railroad Co. has asked for bids on 9000 new steel freight cars to replace the old equipment. Two-thirds of them are for the lines east and one-third for the system west of Pittsburgh.

—

Touraine Co. to Change Its Name to Vim Motor Truck Co.

PHILADELPHIA, PA., Nov. 15—The Touraine Co., this city, has applied for an admendment to its charter changing its name from the Touraine Co. to the Vim Motor Truck Co.

The company is devoting itself exclusively to the production of Vim delivery cars and manufactures one chassis only. Seven types of bodies are mounted on this one standard chassis.

—

Miller Rubber Stock Earns 12 Per Cent

AKRON, OHIO, Nov. 12—The Miller Rubber Co. has declared a quarterly dividend of 3 per cent. This places the stock on a 12 per cent per annum basis, against 10 per cent heretofore. The annual report shows an increase of 30 per cent in gross.

—

Dividends Declared

Miller Rubber Co., Akron, Ohio, quarterly of 3 per cent.

Willys-Overland Co. regular quarterly 1¾ per cent on preferred, payable Jan. 1, to stock of record Dec. 21.

Security Prices Irregular

—

Kelly-Springfield Tire and Paige-Detroit Feature Market with Large Gains

NEW YORK CITY, Nov. 17—Security quotations, though irregular, have picked up in value since their break last week. General Motors rose 23 points; Willys-Overland, 9 points; Maxwell, 10¼ points; Kelly-Springfield common, 219 points; and Paige, 85 points. General Motors on Thursday reached 400, showing pronounced strength. At the top the stock was 318 points above the low of the year, 82, made on Jan. 2. The stock dropped yesterday to 393 after the story had reached Wall Street that the company had declared no dividend. At the closing yesterday, Overland common quoted at 233.

In the tire issues, Firestone with its 50-point drop, and Kelly-Springfield with its 219-point rise, featured the market.

Peerless common dropped 105¾ points, after a 25-point rise last week. Reo rose 9 points, Stewart-Warner common rose 7 points and Maxwell first and second preferred each rose 4 points.

The Detroit quotations, with the exception of 120-point rise on Paige stock, was normal. General Motors common rose 12 points. Continental Motor common dropped 10 points.

—

$100,000 Accessory Firm Formed

FORT WAYNE, IND., Nov. 13—Articles of incorporation have been filed with the Secretary of State for a company composed mainly of Fort Wayne men, who will manufacture accessories for automobiles. The capital stock is placed at $100,000. The firm will have its offices in the Schoaff Building, Fort Wayne. The directors are: T. O. Nelson, William N. Ballou, E. G. Reed, Fort Wayne; W. H. Lillich and H. G. Miller, St. Louis. The concern will manufacture a non-skid apparatus consisting of a pair of shoes operated by compressed air, obtained from the exhaust. The shoes are released by pressing a button and drop to the ground, instantly stopping the car. As they lift the car from the ground the device may be used while tires are being changed.

—

Hundson Metal Products Co. Formed with $1,000,000 Capital

DOVER, DEL., Nov. 12—The Hundson Metal Products Co., to engage in the manufacture and sale of metal castings, metal forgings and shapes and to do a general machinery business, was incorporated here with a capital of $1,000,000. The incorporators are: A. N. Seaman, D. M. Clark of New York City, and H. W. Davis of Wilmington, Del.

—

Toledo-Ford Tire Co. Now Toledo-Findlay Tire Co.

FINDLAY, OHIO, Nov. 15—The Toledo-Ford Tire Co. stockholders met at their general offices here to-day and changed the name of the corporation to the Toledo-Findlay Tire Co., upon the advice of a legal representative of Henry Ford, who claimed the company was infringing upon his rights.

Test Massachusetts Law

Automobile Legal Association Seeks to Prove License Fee Often Double Tax

BOSTON, MASS., Nov. 13—The first move in a plan to test the constitutionality of the Massachusetts motor law was started here this week. William L. Thibodeau, general counsel for the Automobile Legal Association, took a car that was unregistered and drove it on the streets until he was arrested. In the lower court he was found guilty and appealed. The case now goes to the Superior Court, and it is believed it will find the law is all right there, which will allow another appeal to the Supreme Court. The basis of the case will be fought on the plea that motorists now paying a personal property tax are being unjustly taxed in the guise of registration fees. It is the result of the plan to increase the fees on cars and trucks in the next legislature. The Automobile Legal Association has about 9000 members and is a powerful body, with plenty of financial backing, and not identified with any other organization. It is probable that the various automobile organizations of the State will line up on one side or other of the fight.

New Iowa 3-Year-License Law in Force Jan. 1

DUBUQUE, IOWA, Nov. 13—The new automobile registration law in the State of Iowa will go into effect Jan. 1, 1916. The new law provides for number plates which will last three years. An owner paying the license fee for 1916 will receive number plates for the three years.

In 1917 and 1918 notice will be sent from the State to the owners to pay the registration fees for those years.

The fees for registration have not been changed. Machines used four years prior to Aug. 1 will be registered for one-half of the regular fee. Machines purchased after Aug. 1 will be registered that year for one-half the fee.

Under the new law all fees are due Jan. 1. A penalty of 10 per cent will be added if not paid by April 1 and 5 per cent additional for each month thereafter.

Motor vehicles are subject to lien for all unpaid fees.

10 Days in Canada Free

OTTAWA, ONT., Nov. 13—The Customs Department at Ottawa has just granted to United States motorists entering Canada for touring purposes a privilege hitherto denied them, although Canadian motorists have enjoyed the privilege in the United States. Now a non-resident owner of an automobile manufactured abroad desiring to bring his machine into Canada for a stay of not more than ten days may be granted a free permit at the discretion of the customs collector at the port of entry, provided that the latter is satisfied of the good faith of the motorist. Hitherto American motorists have had to make a formal entry and file a bond costing about $5.

Boyce Motometer Injunction Against Stewart-Warner Made Permanent

NEW YORK CITY, Nov. 12—The temporary injunction granted May 16, 1914, by the district court here to Harrison H. Boyce and the Motometer Co., Inc., against the Stewart-Warner Speedometer Corp., and which was affirmed by the circuit court of appeals last December, has been made permanent. The injunction prohibits the Stewart-Warner corporation from infringing the Boyce Motometer patent by the manufacture and sale of a radiator cap thermometer adjudged by the court to be an infringement of the Motometer.

The suit was brought by Harrison H. Boyce and the Motometer Co., Inc., against the Stewart-Warner Speedometer Corp. April 11, 1914, in the United States district court for the southern district of New York. Stewart-Warner answered May 1, claiming that the Motometer patent was void for lack of invention. The court, however, upheld the validity of the patent and issued the temporary injunction, which has now been made permanent, after having been affirmed by the circuit court of appeals last December. The Stewart-Warner corporation stopped the manufacture of the infringing device as soon as the temporary injunction was issued.

Rumely Plant Sale Dec. 9

SOUTH BEND, IND., Nov. 15—Official notice of the sale of the plants, including real estate, improvements, machinery, patents, trademarks, records, personal property, etc., of the M. Rumely Co., Laporte, gives Dec. 9 at noon, in the main offices of the Rumely company in Laporte, as the time and place, with Receiver F. P. Mount as special master. So far as known the Advance-Rumely Co. will be the only bidder for the property. This is the name of the reorganized company.

New Plant for Bukholt

STEVENS POINT, WIS., Nov. 13—The Bukholt Mfg. Co., Stevens Point, Wis., manufacturing a line of tire and automobile accessories, has broken ground for a new three-story factory, to be 74 by 100 ft. The building will be ready about Feb. 1. In the meantime overtime operations are the rule in the present plant.

A. A. A. Board Fines Oldfield

For Demonstration Performance at Outlaw Race Meet —To Revise Rules

NEW YORK CITY, Nov. 11—At the regular meeting of the Contest Board of the American Automobile Association, held at headquarters here to-day, Barney Oldfield, veteran driver, was fined $250, for driving a demonstration performance in his car on a track at Wichita, Kan., where an outlaw racing meet was being held. Oldfield was advertised as a co-attraction with outlaw drivers, but did not drive in competition. His performance was made in company with an aviation performance by aviator Thompson. This is the second time where the fine penalty has been imposed on drivers and companies for infraction of rules during the last year, and it seems a relatively just punishment.

The board took up the work of revising the contest rules for 1916 which work will be completed before the first of the year.

The board has been requested to issue sanction covering meets in the Philippine Islands, which will be done.

Several drivers who have violated the rules during the past year were reinstated and others denied application for reinstatement. Among those reinstated are: D. K. Sworder, G. C. Bergdoll, Herbert M. Strachan, A. A. Mattison and B. Ward Bean. Applications for reinstatement were denied Arthur Klein and William B. Brown. The following drivers were disqualified for different periods: C. E. Wood, two years, Henry Skutt, A. Ingram, and M. J. Crell, until January, 1917. James B. Ryall and John A. Maiss were disqualified for one year. Frank Topping, a registered mechanic who has violated the rules during the present year, was placed on the ineligible list.

Cooper to Try for Non-Motor-Stop Record in Maxwell

LOS ANGELES, CAL., Nov. 16—Earl Cooper, driving a 1916 stock Maxwell, is going to try for a non-motor-stop long distance mileage run in and around this city during the present month. The stock status of the car is being established, a sanction has been obtained from the American Automobile Association, and official inspectors and technical committee will be employed.

Killen-Strait Gets War Order

APPLETON, WIS., Nov. 13—The Killen-Strait Mfg. Co., Appleton, Wis., builder of the Strait tractor, a 50 hp. gasoline or

kerosene machine, has booked an order for tractors which will not only tax its capacity for more than twelve months but oblige the company to contract for a large supply from outside manufacturers. The tractors will be sent to European governments for use in military operations. William Strait, designer, has just returned from Europe after a 4 months' stay, during which he demonstrated four models of the tractor on the field. The order calls for thirty to thirty-five tractors a week.

—

Three More Car Exhibitors

NEW YORK CITY, Nov. 15—The newest additions to the list of show exhibitors are the Barley Mfg. Co., which is to exhibit the Halladay car at the Chicago show, and the S. G. V. car, which is listed to exhibit at the New York show. Application for space has been received from J. B. Ferguson, Ltd., of Belfast, Ireland, and this firm will exhibit a chassis of the Fergus car in all probability. The Fergus is of 14-20 hp., is equipped with a four-cylinder motor and has many mechanical features which will command attention.

—

Milwaukee Show Jan. 7-13

MILWAUKEE, WIS., Nov. 13—The Milwaukee Automobile Dealers, Inc., has selected the week of Jan. 7 to 13, inclusive, as the date for holding the annual Milwaukee show in the Auditorium. As for two years past, the show will be opened on Friday evening and close on the following Thursday night. Bart J. Ruddle, assistant secretary of the M. A. D., will again be show manager.

—

Franklin Off on Oil Test

NEW YORK CITY, Nov. 17—A Franklin six left the headquarters of the Automobile Club of America to-day en route for Chicago. The car is accompanied by two A. C. A. observers who will note the consumption of gasoline and oil along the route. The first stop will probably be in Philadelphia. An effort is to be made to make the entire distance on 1 gal. or less of lubricating oil.

—

Accessory Department at Baltimore Show

BALTIMORE, MD., Nov. 13—Owing to the numerous demands by the dealers in accessories and supplies the committee in charge of the show that will be held in Baltimore Jan. 18 to 22 have decided to set aside a big room in the Fifth Regiment Armory, where the show will be held, for the showing of accessories. Applications for all space for cars, both passenger and commercial, as well as for the accessory division, must be made before Dec. 10, and drawings for the space as to location will be made on Dec. 20.

80 Exhibitors at Providence

—

144 Passenger Cars and 32 Trucks on Display—First Night Attendance 10,000

PROVIDENCE, R. I., Nov. 12—The annual show of the Rhode Island Automobile Dealers' Association, and the first automobile exhibition of the season in the East, opened here this evening with eighty exhibitors showing forty-five passenger and seventeen commercial makes. It will continue through until Nov. 20. The show is being held in the State Armory. The passenger cars, numbering 144, are on the main floor, with the thirty-two commercial vehicles in the basement with the accessories. The attendance at the opening this evening was large, running well above 10,000.

—

Fifth Avenue Buses Earn $1,451,508.10 in Year

NEW YORK CITY, Nov. 16—The Fifth Avenue Coach Co., this city, during its fiscal year, ending June 30 last, carried 14,050,471 passengers at 10 cents each, in its 133 buses, its revenue from this source amounting to $1,405,047.10, or 34.52 cents per active bus mile. The total mileage of the buses, including 43,929 idle miles, was 4,113,625. Its revenue from the livery service, amounting to 19,374 bus miles, was $15,086, and the advertising in its buses amounted to $31,375, thus bringing the total revenue from operation up to $1,451,508.10, just $274,857.72 more than the previous year.

A feature brought out in the report of the company is that the 133 buses ran at a cost of only 1.504 cents per bus mile, each bus using six tires, the rear wheels each having two tires. Last year the cost was 1.7 cents; the previous year, 2 cents; and the year before that, 3.13 cents. This greater tire mileage is attributed to a better grade of rubber; better supervision; better drivers; better brake mechanism; and the use of steel wheels instead of wood. The company paid out in tire maintenance during the year, $61,941.10.

—

Studebaker to Build Branches in Portland and Dallas

DETROIT, MICH., Nov. 12—Officials of the Studebaker Corp. are now in Portland, Ore., and also in Dallas, Tex., where it has been decided to erect Studebaker branches. The plans for the new buildings are not yet finally approved, but it is said that they will be from four to six stories high and will have at least 50,000 sq. ft. of floorspace.

The new branch house in Kansas City, Mo., is nearing completion and will probably be occupied by Jan. 1. Fronting on Grand Avenue, the structure will be five stories high, while on the Twenty-first Street side it will have six stories. On the first floor there will be the show rooms and offices for both the retail and wholesale branches. Repair parts and stock will be kept on the second floor, and on the other floors cars will be stored. The basement will be used partly as repair shop and partly as shipping and receiving room.

—

Overland Stores Co. Buys Bowman & Libby, Inc.

MINNEAPOLIS, MINN., Nov. 13—The Overland Stores Co. has bought the business of Bowman & Libby, Inc., distributor of Overland and Willys-Knight cars at 1203 Hennepin Avenue, and will conduct a factory branch there. The Minneapolis company controlled a large Minnesota territory, as well as contiguous territory in Wisconsin, Iowa and South Dakota. F. N. Coats, formerly of the Toledo office, is now manager and will live in Minneapolis and divide his time between the main office and the new wholesale house in the Midway.

Cars will be placed in the new warehouse of the company this month. Operation will start by Jan. 1, or sooner. The plant will be for wholesale storage, sales, service and repairs. Duplicate parts will be carried also. The building covers about 10 acres and has railway connection with all steam lines entering Minneapolis and St. Paul. The floorspace is 432,450 sq. ft., the building being 186 by 465 ft. and five stories.

—

Northwest Hupmobile Co. Formed

MINNEAPOLIS, MINN., Nov. 12—The Northwest Hupmobile Co. has been organized here, with S. D. Briggs, formerly with the Pence Co., as manager. The new company will handle the wholesale distributing of the Hupmobile for North Dakota, the eastern part of Montana, Minnesota and the western part of Wisconsin.

—

Firestone Day in Des Moines

DES MOINES, IOWA, Nov. 13—H. S. Firestone, head of the Firestone Tire & Rubber Co. of Akron, Ohio, was the central figure of a gathering of over 200 Iowa dealers in Des Moines on Nov. 10 for the celebration of Firestone Day. R. J. Firestone, general sales manager of the company, also was in attendance. An entire day of festivities was followed by an evening banquet addressed by the Messrs. Firestone and by Lafe Young, Sr., former United States Senator, and publisher of the *Des Moines Capital;* Harvey Ingham, editor of the *Des Moines Register;* Henry Wallace, editor of *Wallace's Farmer,* and others.

U. S. Army Wants More Trucks

Dept. Commanders and Quartermasters Recommend Increase of Motor Service

WASHINGTON, D. C., Nov. 13—Recommendations made this year by department commanders and quartermasters indicate that there is a growing desire to obtain additional motor trucks as a means of transportation for military supplies at army posts and in the field.

The quartermaster of the Hawaiian department has made a special report on transportation in the Hawaiian Islands and he has recommended that motor-truck transportation be substituted, in part, for mule and escort-wagon transportation, and that one 6-ton truck for general hauling and one 3½-ton truck with dump body for coal be supplied to the quartermaster depot at Honolulu, in addition to the three 1½-ton trucks now on hand there.

The army medical department also is negotiating for purchase of additional motor ambulances, and a board shortly will make a report concerning the type best adapted for use in connection with field hospitals.

—

Must Give Factory Numbers When Registering Cars in Ohio

COLUMBUS, OHIO, Nov. 13—To make identification easier, State Registrar of Automobiles W. H. Walker will require all applicants for licenses to give the serial factory numbers of their machines when they apply after the first of the year. With this information on file the department will be better enabled to trace the owners of stolen cars.

Each application for a license now in addition to giving the full name and address of the applicant, must give the name, make, motive power, style and horsepower of the machine.

Registrar Walker intends to establish a number of branch offices next year from which licenses will be issued just the same as from the main office in Columbus.

—

Reorganize Wisconsin Automobile Business Association

MILWAUKEE, WIS., Nov. 16—Milwaukee garagemen, supply makers and dealers and others interested in the automobile business have undertaken to reorganize the Wisconsin Automobile Business Assn., which was organized about a year and a half ago but after brief activity went to sleep. A meeting was held Nov. 11 on call from the officers, and plans laid for a reconstruction of the association on broad lines. The officers are: President, W. J. Schubert, Milwaukee Auto Specialty Co.; vice-president, F. A. Olsen, Curtis Automobile Co.; secretary, Roland Moeller, Auto Service & Supply Co.; treasurer, Oscar F. Fischedick, Auto Supply Co., all of Milwaukee. The association has a membership of 255 and under the new plan will increase this to at least 1000.

The business has been divided into ten distinct sections, each of which will be organized separately but be a part of the association. The first work will be to weld together the garagemen and repair-shop keepers. Fred C. Carter, of the Auto Livery Co., was named chairman of of this division, and H. E. Wilson, secretary. Meetings will be held in four quarters of the city so that all men in this line of business can be reached directly and intimately. Other divisions to be organized are: Car dealers and salesmen; tire dealers; painting and trimming shops; electrical repairmen; publishers to the motoring industry; gasoline and oil dealers; accessory and supply makers; jobbers and dealers in accessories and supplies, etc.

—

Delco Repairs, Gratis, Equipment Damaged in Texas Storm

DAYTON, OHIO, Nov. 12—The Dayton Eng. Lab. Co., this city, has to date repaired, without charge, fifty-four cars on which the Delco electric systems had been damaged by the storm and flood in the neighborhood of Galveston, Tex. Of these five were Cadillacs, sixteen Buicks, seven Oaklands, ten Hudsons, seven Coles, three Cartercars, five Oldsmobiles and a Moon. The company is in receipt of a number of letters of appreciation of this service from Galveston, Beaumont and Port Arthur, Tex.

—

Vogler in New York for Maxwell—Garth Succeeds Him in Philadelphia

PHILADELPHIA, PA., Nov. 15—J. R. Garth has succeeded H. J. Vogler as district representative in this territory for the Maxwell Motor Co., Mr. Vogler having been appointed metropolitan district representative in New York for the same company.

—

F. Shirley Boyd Dead

BOSTON, MASS., Nov. 13—F. Shirley Boyd, one of the pioneers in the accessory trade in Boston who began with the old bicycle regime, died last Friday following an operation for appendicitis. He had built up one of the largest accessory businesses in New England, handling many well-known accessories.

—

Olds Branch Heads Meet

LANSING, MICH., Nov. 11—The annual fall meeting of the heads of branches of the Olds Motor Works, also the district traveling men and the salesmen who act as district representatives has just been held. The men were here five days and went over all the details of the plans of the 1916 season. A talk was given by W. H. Mooney, installation engineer of the Dayton Engineering Laboratories which makes the Delco starting and lighting system. Another of the talks was by William Farr, who spoke about the Johnson carbureter. This carbureter and electric system are part of the Oldsmobile equipment.

George Robertson Joins Dunlap Tire Distributor

NEW YORK CITY, Nov. 13.—George H. Robertson, prominent in the automobile racing field, and recently president of the Auto Supply Co., this city, and later eastern district manager of the Houk Mfg. Co., Buffalo, N. Y., has joined Otto Braunswarth, this city, as vice-president. This company is the American distributor of the Canadian Dunlap tire.

—

M. A. M. Adds List Dept.

NEW YORK CITY, Nov. 12—The Motor and Accessory Manufacturers which counts 238 manufacturers of automobile accessories in its membership roster, has recently added to its activities by adding a new department which is prepared to do addressing work for all of its members. The association has compiled in stencil form a list of over 2,000,000 automobile owners and has classified these according to make of car so that any accessory maker can readily address all of these owners in any city, State, or part of the country. The working of this department, which has been under way for a couple of months, is that any member of the accessory organization can forward his envelopes, have them addressed, and returned to his business office. The list is only open to accessory makers who are members of the association.

To properly carry on this work the Motor and Accessory Manufacturers have secured space at 225 West Fifty-seventh Street, where this work is carried on, and where they have a force of 100 men and girls engaged in compiling their lists, making stencils and doing the addressing work.

—

Neuman to Distribute Chalmers

MILWAUKEE, WIS., Nov. 15—Harry Newman, Inc., Chicago, Ill., has been appointed distributor for Chalmers cars in the State of Wisconsin, southern Minnesota and northern Michigan, supplanting the Hoppe-Hatter Motor Co., Milwaukee, Wis. The Newman company has leased the former Packard garage at Grand Avenue and Seventh Street, as headquarters and service station. Branch service stations and salesrooms are to be established in every city of consequence in the territory.

Factory Miscellany

Tire Fabric Co. Adds—The Killingly Mfg. Co., Killingly, Conn., maker of automobile tire fabrics, will construct a weave shed in that city.

To Make Tops in Vincennes—J. D. Browdues, Martinsville, Ind., will establish a factory at Vincennes, Ind., for making automobile tops and bodies.

Arrow Co.'s Plant Started—The Arrow Manufacturing Co., has broken ground for a new factory located at Broadway and Emerald Avenue, Toledo, Ohio, to be 60 by 120 ft., three stories high and to cost $20,000. The concern makes electrical apparatus of all kinds.

McClurg Finishes First Tires—The McClurg Rubber Co., Coshocton, Ohio, has completed its first tire. The first actual work of turning out tires in the new plant started last week. Four or five extra men began work recently making a total of about thirty men now employed there.

Hartford Co. to Make Bearings—The Rockwell-Drake Corp., Hartford, Conn., has been incorporated with a capital of $100,000 to make bearings, automobile parts, machines, etc. The incorporators are H. M. Rockwell, L. A. Drake and R. J. Brault of Bristol and R. B. Bennett of Hartford.

To Make Tires in Buffalo—The George Miller Spring Tire Co., Buffalo, N. Y., has been incorporated with a capital of $100,000 and will establish a plant for the manufacture of tires, springs, etc., for automobiles and other vehicles. G. and O. Miller and W. L. Williams, are the incorporators.

To Make Automobile Wheels—The Mutual Wheel Co., Moline, Ill., which has previously limited its output to wheels for wagons, buggies and farm machinery, has embarked in the manufacture of wooden wheels for automobiles. A special building has been erected to carry machinery for the new department.

To Make Towing Truck—The Projecta Co. has been organized at East Milton, Mass., to manufacture the Projecta towing truck. It is designed to meet the demands of owners whose vehicles have been disabled at front or rear and allows the part to be rigidly jacked up and towed for long distances at good speed.

Crow to Increase Production—The Crow Motor Car Co., Elkhart, Ind., has received orders for 200 cars to be furnished to its Kansas City distributing agency, the Velie Motor Co., during the next 90 days, and the Kansas City firm has contracted for 600 cars to be placed in Kansas and Oklahoma during the 1916 season. The Crow company is planning to increase its winter production to 200 cars a month and its spring production to 300 cars a month.

1238 Hupmobiles in October—Sales Manager Lee Anderson, of the Hupp Motor Car Co. Detroit, Mich., states that during October the company shipped 1238 cars, this being the biggest October business in the company's history. The number of inclosed cars shipped was 300 per cent better than last year. The demand for the winter car is general throughout the country, and is such that the original production schedule as to this line of cars had to be changed to increase the output of limousines, sedans and year-'round touring types of cars.

To Make Wheels—The Ideal Wheel Co., Massillon, Ohio, has been formed in this city for the purpose of manufacturing wheels for automobiles, motorcycles and aeroplanes. No directors or officers have been elected yet. It is reported that the Ideal wheel will be constructed of steel, that steel springs will be used as spokes, and tires will be of the airless cushion type. The company will start business by making automobile wheels and will employ about twenty-five men. Arno Merkel of Cincinnati, one of the owners of the patent on this wheel, will be general manager of the concern.

The Automobile Calendar

Nov. 12-20	Providence, R. I., Show, State Armory, Rhode Island Automobile Dealers' Assn.
Nov. 20	Arizona 150-mile Grand Prix.
Nov. 22-27	Binghamton, N. Y., Show, State Armory, Binghamton Automobile Dealers' Assn.
Nov. 23	Phoenix, Ariz., Grand Prix Race, State Fair Course.
Nov. 29-Dec. 4	Electric Prosperity Week.
Dec. 5	Worcester, Mass., American Road Builders' Assn. Day.
Dec. 6-11	Springfield, Mass., Show, Auditorium.
Dec. 7-10	New York City, American Society of Mechanical Engineers Convention.
Dec. 31-Jan. 8	New York City, Sixteenth Annual National Automobile Show; Grand Central Palace; National Automobile Chamber of Commerce.

Sept. 4	Des Moines Track Meet.
Sept. 15	Indianapolis Track Race.
Sept. 16	Providence Track Race.
Sept. 30	New York City Sheepshead Bay Race.
Oct. 7	Omaha Track Race.
Oct. 14	Chicago Track Race.

The Week in the Industry

Holsworth Joins Fickling—Percy Holsworth, formerly of the Yellow Taxicab Co., has associated himself with the Fickling Enameling Corp., Long Island City.

Rosenwald Joins Detroiter Co.—The Detroiter Motor Car Co., Detroit, Mich., has appointed F. K. Rosenwald assistant in the sales department of the company.

Duggan Denver Briscoe Mgr.—G. A. Duggan is now manager of both the Estarado Garage, 1530 Clarkson Street, and the Briscoe Auto Sales Co., 1646 Broadway, Denver.

Ross Midgley Columbus Mgr.—C. E. Ross has been made manager of the Columbus, Ohio, branch of the Midgley Tire and Rubber Co., located at 224 North Fourth Street.

Kressler Leases Plant—The Kressler Auto Co., organized by G. P. Kressler, P. J. Blazer and Henry Ockchin, has leased the abandoned plant of the Fostoria Stave and Barrel Co., Fostoria, Ohio, which will be occupied after Dec. 1.

Gordon Leaves Boston White—H. M. Gordon, for the past nineteen years identified with the White Co.'s branch at Boston, Mass., with the position of purchasing agent, resigned last week to join the Boston branch of the Kelly-Springfield Tire Co.

Reeves Heads Brooklyn Chevrolet Sales—M. C. Reeves has been appointed sales manager of the Chevrolet Motor Co., Brooklyn, N. Y. Mr. Reeves was formerly connected with this branch as salesman and has been recalled from the factory field work to this present position.

Taylor with N. J. Car Spring Co.—L. H. Taylor, formerly salesman for the Denver branch of the B. F. Goodrich Co., is now Western manager for the New Jersey Car Spring & Rubber Co., in charge of Colorado, New Mexico, Utah, Wyoming and Montana, with headquarters at 238 Temple Court Bldg., Denver.

Wilkins Maxwell Supervisor—F. W. Wilkins, formerly manager of the Maxwell Motor Co.'s interests in Saskatchewan, has been made supervisor of the company's trade in Western Canada succeeding C. L. Acherson in that post. Mr. Acherson has been transferred to Windsor, Ont., and given charge of the distribution of Maxwell cars for the whole of Canada. The change came into effect this week. The Maxwell company has seventy-two dealers in the province of Saskatchewan.

Motor Men in New Roles

Gans Heads Indianapolis Studebaker—E. W. Gans has been appointed manager of the Indianapolis Studebaker district.

Lemon a Denver Mgr.—R. I. Lemon, recently manager of the Colorado Springs Auto Equipment Co., is now manager of the Denver Auto Goods Co., 1600 Broadway.

Bradford Mgr.—W. C. Bradford, recently manager of the Auto Livery Co., Denver, is now garage manager for the Denver Omnibus & Cab Co., 601 East Eighteenth Avenue.

Serfas Co. Opens Fourth Garage—The Serfas Motor Car Co., Lehighton, Pa., has opened its fourth garage in Pottsville, Pa. The others are located in Lehighton and Mauch Chunk.

Roberts Hupp Rep.—H. R. Roberts has been named as Northwestern representative for the Hupp Motor Co., with headquarters at Portland, Ore., and with territory covering Oregon, Washington, Idaho and Montana.

Huntoon in Portland—C. S. Huntoon of the White Co., will hereafter make his headquarters in Portland, Ore., yet covering the territory of Oregon, Washington, Idaho, Montana and British Columbia for the White Co.

Doan Heads Portland Saxon—W. B. Doan has been named distributer of Saxon cars throughout the State of Oregon and will head the Saxon Motor Sales Co. of Oregon, which will be located at 31 North Nineteenth Street, Portland.

Eubanks Heads Halladay Sales—P. J. Eubanks has assumed charge of the sales department and will hereafter look after all matters pertaining to advertising and distribution of the Halladay cars manufactured by the Barley Mfg. Co., Streator, Ill.

De Laite Velie Mgr.—H. R. De Laite, who has been identified with the Velie Motor Vehicle Co. for the past five years, has been appointed manager of the Hampden County agency which the company has opened at Springfield, Mass., with salesrooms at 379 Worthington Street.

Hurd and Cole F. W. D. Reps.—J. S. Hurd and F. A. Cole have joined the Four Wheel Drive Auto Co., Clintonville, Wis. Mr. Hurd was formerly associated with the Gramm-Bernstein Co., Lima, and will be a traveling representative. Mr. Cole will travel in the capacity of a representative of the company.

Joins Automobile Spring Force—C. M. White, Jr., who was formerly manager of the Detroit office of the Stromberg Motor Devices Co., and previous to that of the Detroit office of the Firestone Tire & Rubber Co., has become associated with the selling end of the spring department of the Detroit Steel Products Co.

White Springfield Overland Mgr.—M. T. White has been appointed manager of the new distributing station being erected for the Willys-Overland Co., Springfield, Mass. The new structure will be four stories of reinforced concrete with a 75-ft. frontage on Chestnut Street and 230 ft. depth on Winter Street. Mr. White has opened temporary salesrooms on Worthington Street.

Foster Resigns—J. W. Foster, manager of the Denver Auto Goods Co., 160 Broadway, Denver, and a member of that firm, has sold his interest and resigned as manager. He is well known to the trade in the Rocky Mountain district, being first vice-president of the Automobile Trades Assn. of Colorado and a vice-president of the Retail Credit Men's Assn. of Denver and the Associated Garages of America.

Harry S. Houpt to Make Changes—Harry S. Houpt, president of the Hudson Motor Car Co., New York City, has promoted De Witt Voorhis, assistant secretary and treasurer of the company and H. C. Huber, at present controller of the organization.

Mr. Voorhis will be made manager of the New Rochelle branch which on Jan. 1 will open a salesroom at Main Street and Centre Avenue. Mr. Huber will then become assistant secretary and treasurer of the company.

Curtiss and Ellis Make Change—H. R. Curtiss, for several years manager and treasurer of the Splitdorf Electric Co.'s New England branch at Boston, Mass., has been appointed manager and treasurer of the Excelsior General Supplies Co. at Chicago.

R. M. Ellis, for the past two years export manager of the Splitdorf Electrical Co., with headquarters at New York, has gone to Boston to assume charge of the company's branch there. He was formerly manager of the Bi-Motor Equipment Co. at Boston and is well known in that city.

VOL. XXXIII. NEW YORK—THURSDAY, NOVEMBER 25, 1915—CHICAGO No. 22

The AUTOMOBILE

Tire Makers Enlarge Plants and Develop Product

60,000 Tires a Day—Straight-Side Pneumatic Heavy Gainer—Pressed-On Solids Displace Demountables —Factories Lead in Employees' Welfare Work

OVER 15,000,000 pneumatic tires will be needed to care for the motor car business in America in 1916. There are to-day in excess of 2,200,000 motor cars registered in the country. Add to this perhaps 700,000 cars that will be built by July 1, 1916. When you have added these cars to those already registered your total is 2,900,000 cars. Give five tires to each car and you get a tire total of 14,500,000 tires needed. Some cars will require more than five tires, but five is a conservative average.

To produce this number of tires there are to-day forty tire factories that are manufacturing pneumatic tires. Some of these produce more than 10,000 tires per day, others build 7500, others 1000, others 300, some 100, some 60, and a few but 40 tires per day. While Akron is looked upon as the tire mecca of America, a title it properly deserves, yet other tire centers are springing up, the State of New Jersey, occupying a mid-position between such population centers as New York and Philadelphia, being a particularly active tire center. Pennsylvania and New England have large interests.

To manufacture 14,500,000 tires in a year means to do this in 300 working days. Divide 14,500,000 by 300 and you get over 48,000; in other words our tire factories for home consumption will have to produce approximately 50,000 tires a day to meet the demand. This will not take care of our export trade which is developing, so that it will not be surprising if production may reach 60,000 a day in certain parts of the next few months.

Unparalleled Activity in the Field

Not for years, if ever in its history, has there been so much activity in the tire field. Expansion is in the air. New buildings have been going up all season and to-day the rush of construction is greater than ever. In Akron the big companies are adding enormously to their plants, some of them increasing their output 50 per cent; in other parts of the country some factories are doubling their capacity. The increased output of cars during the past year has necessitated these additions as well as the prospects for increased car outputs for 1916. This numerical growth is alone responsible for much tire factory development, but in addition comes the increase in export business.

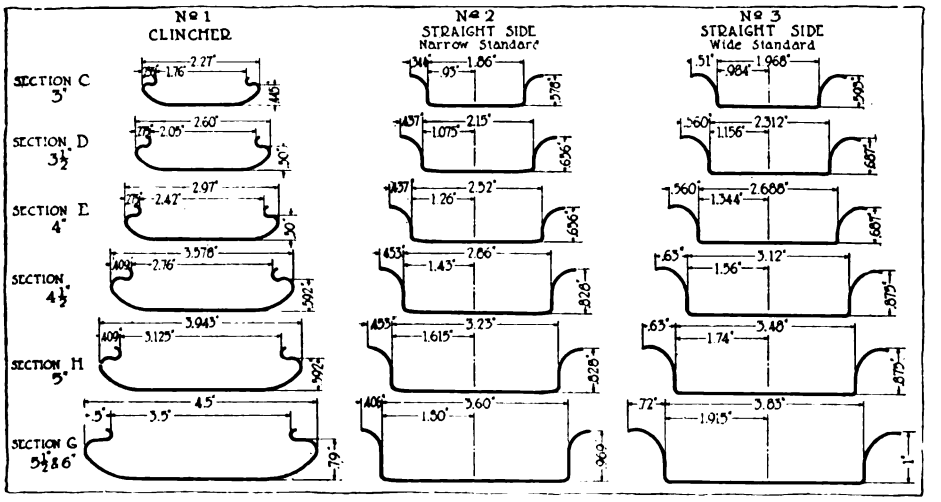
Extend Factory Facilities

To care for these increased tire demands factory additions have been the program of the year, the normal increase in the number of cars in use from year to year creating corresponding increase in tire factories. The Akron makers are among the leaders in this building wave, but other sections of the country are equally active. Firestone is at present working on nine new wings or factory additions which when completed will add 11 acres of floorspace, giving a total of thirty-two acres of floorspace. These wings are nearly all of the same size, measuring 120 by 80 ft., five stories high. In addition the company is erecting a large club house for its employees. The company hopes to double its output of solid tires and increase its output of pneumatics by 80 per cent.

Goodrich and Goodyear, the two largest producers in Akron, are adding to floor area, Goodrich erecting several large buildings, part of which will be used in its cord tire work and part in its line of rubber goods other than tires.

Kelly-Springfield has increased its floorspace 25 per cent during the year and its manufacturing facilities 200 per cent during the past eighteen months. Swinehart has added facilities in the last year to double its tire output.

Outside of Akron the program of additions continues. Fisk is making additions that when completed will give it about 20 acres of floorspace for making pneumatic tires. It has just completed a five-story reinforced concrete warehouse and the foundations are under way for a new factory building. The Pennsylvania company last year added a new building 140 by 200, six stories high. Ajax has just added a new curing room 50 by 100, one story, and is erecting a new factory building 250 by 300 ft., three stories high. The



Standard clincher and straight side rim sections

Falls Rubber Co. has a new plant 80 by 800 ft. with three stories and basement. The New Jersey Car Spring & Rubber Co. has doubled its floor area devoted to tire manufacture during the year.

Several new concerns have entered the field during the year, one being the Midgley Tire & Rubber Co., which started last spring in Lancaster, Ohio.

Too Many Sizes

The curse of the pneumatic tire business has been too many tire sizes, too many models. The Society of Automobile Engineers has been working for several years to reduce the number of tire sizes, and last January recommended the following as the standard sizes for pneumatics, having in all but nine different sizes, with the nine corresponding oversizes, making eighteen in all. Unfortunately this does not mean that the tire maker has only to produce eighteen different tire models; far from it. He has to make these in straight-side types, in quick-detachable clincher types, and some of the smaller sizes in the soft-bead clincher type for cars that use the clincher rim instead of the quick-detachable rim. But you can go further—the tire maker has to produce these in plain treads and also in non-skid treads, so that if these nine sizes were produced in all of these different lines the tire maker would have over seventy different tire models. Add to this the cord tires that are being produced, and if you filled the entire field with the cord models you would have close to 150 different models of tires, truly a big load for the tire manufacturer to produce.

The nine recommended S. A. E. tire sizes with their corresponding oversizes and also the necessary rim sizes for each are:

Rim Sizes Inches	Even Tire Sizes (for Manufacturers and Consumers) Inches	Odd or Oversize Tires (for Consumers Only) Inches	Tire Seat Diameter Inches
30x3	30x3	31x3½	24
30x3½	30x3½	31x4	23
32x3½	32x3½	33x4	25
32x4	32x4	33x4½	24
34x4	34x4	35x4½	26
34x4½	34x4½	35x5	25
36x4½	36x4½	37x5	27
36x5	36x5	37x5½	26
38x5½	38x5½	39x6	27

The object in recommending oversize tires only for consumers is that if an automobile manufacturer fits an oversize tire on his car when sold, the purchaser of that car has no opportunity of fitting any other tire size; whereas, if automobile makers will only fit the standard tire sizes it always leaves the owner with the option of fitting the oversize if so desired.

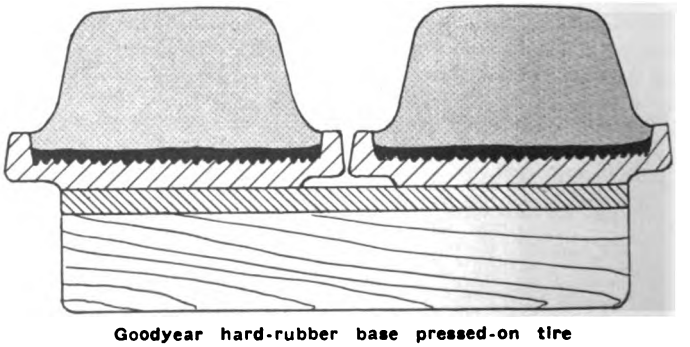
The American tire industry is fortunately free from the annual-model millstone that is clinging to the automobile business. Each autumn does not bring out any new announcement of the 1916 line of tire models. If the tire maker has a new anti-skid tread to announce he announces it in July or October, according as he is prepared to meet the demand. If he has a new hard rubber base solid for trucks he makes his announcement of it when ready, and there is no labeling it an annual model or anything of the kind. It just goes down on the price list as one more type or size.

There are few changes made in pneumatic tires from year to year. The tire contour has been well worked out. There is very little by way of adding a new layer of fabric. The thickness of tread, the formation of the bead or base and the general problems have been well worked out for several years, consequently it is not disappointing to get the reply, "There is little if anything new in our tires," as an answer to the question, "What is there new in your tires for 1916? What new models have you brought out? What are the improvements?"

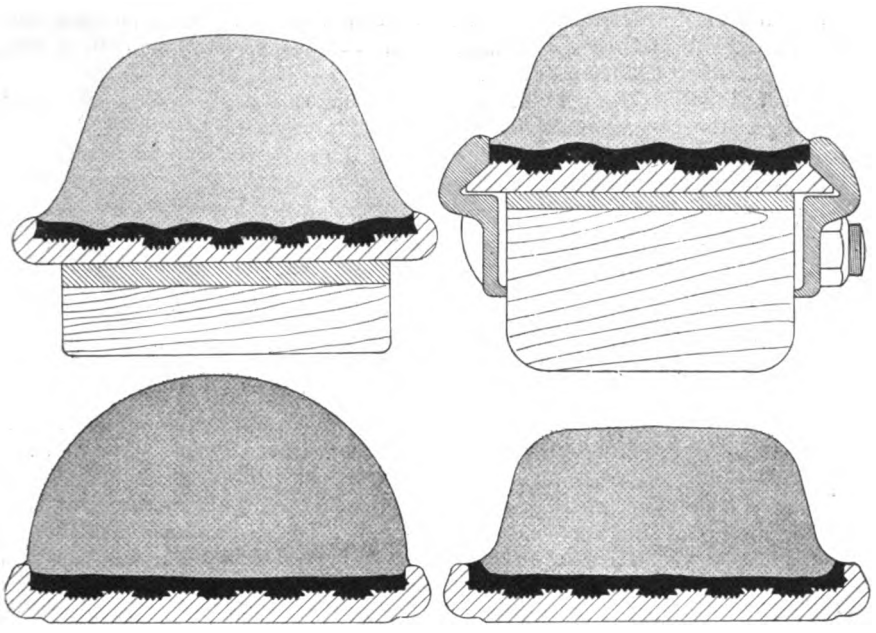
Do not infer that the tire makers are idle; far from it. They all have their corps of tire engineers. Instead of an engineering department at the tire factory it is generally designated the "experimental department." Here the large tire makers have a corps of graduated engineers and the walls and tables are covered with blueprints, just as in a car factory. Draftsmen are busy the year round. Consultations are going on every day and conferences on design and manufacture are a part of the regular program. Go to the garage of the factory and there you may see twenty or more test cars fitted with all kinds of experimental tires, each car being watched very carefully and the performance of all experimental tires watched with the utmost care. All these experimental tires look alike, excepting where a different tread is used. To the novice they are the same, but to the tire engineer, to the head of the experimental department, they are as interesting and different as the new car in the engineering department.

No. 1 car is fitted with tires in which a heavier fabric is used. No. 2 car uses rubber of a new compound; No. 3 has been vulcanized a little differently; No. 4 has the tread slightly different. So the differences go, each tire playing its role in the great enterprise of tire evolution which has been going forward restlessly since the opening days of the present century, identical as the engineers of the car are changing the axle design, adding lighter pistons, using new bearings for the crankshaft, improving the grade of steels in the gears, installing improved bearings in the back axle, using a stamping where a forging had previously been used, etc.

Restless evolution, never ceasing, but concentrating into fabric and rubber the brains of thousands each year, all to make the car go farther on a set of tires, make it consume fewer gallons of gasoline per hundreds of miles, and make it



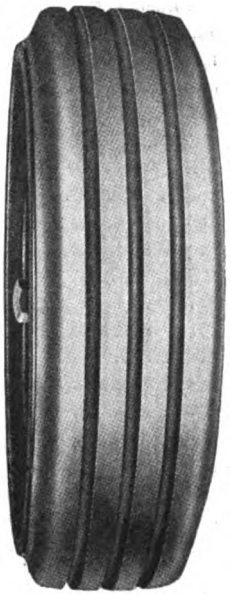
Goodyear hard-rubber base pressed-on tire



Goodrich pressed-on and demountable types. De Luxe deep-section Goodrich on left

Giant Firestone solid to replace twin tires of 6 and 7-in. sections

Alternative sections of Hood hard-rubber base tires, European section at left and American section at right



a better medium to absorb the vibration of the car. No, tire engineers are not idle. Their work is not spectacular, and while the name of an automobile engineer is heralded from ocean to ocean when he brings out a new design of motor, we rarely if ever see in print the name of the tire engineer, yet he is doing his work to improve quality and cut down production costs.

Tire making bears a resemblance to the steel industry: the progress in the fabrication of steel parts in the car has been responsible for many car improvements. By producing better alloy steels we have been able to lighten parts and yet have them much stronger. Add some ingredient to a steel and you make it tougher. Add another ingredient and you give it the ability to withstand fatigue under constant strain.

Go to the tire engineer and he is working in chemistry just the same as the steel man. Take a trip through the calendering room of a tire factory where the crude rubber and the score-and-one chemicals entering into a tire are thrown into metal boxes a couple of feet square, and there you see the starting of the tire.

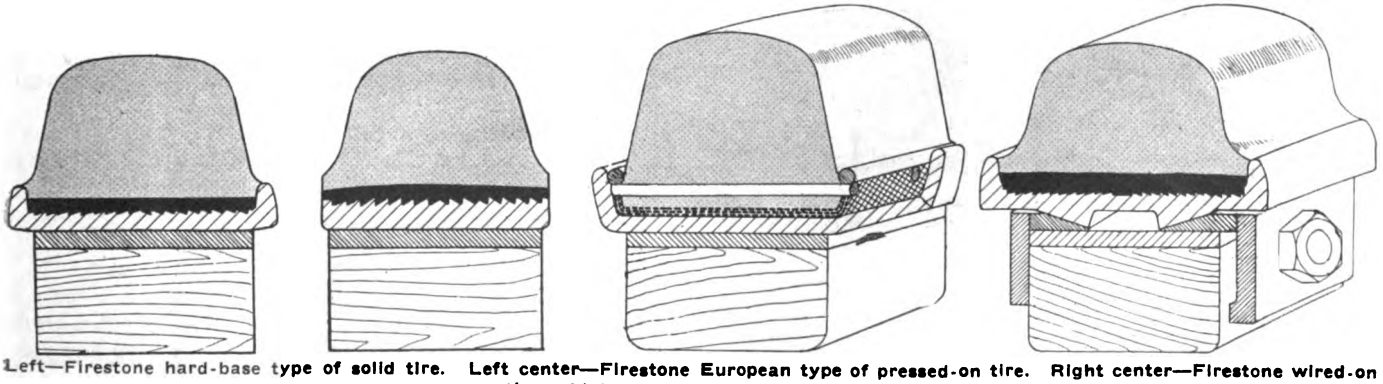
It's an indecipherable mass. You recognize the lumps of black crude rubber. If you have the cultivated rubber eye you can tell whether the rubber is the Para gum from the forests of the Amazon or the better washed product from the plantations of the East Indies and the Straits Settlements, or perhaps from the Congo in Africa. All three may be in the one box, and mixed with them are the chemicals, some yellow powders, some black, others green and others of nearly every color in the rainbow. You see all, you walk between rows of these piled on the floor like baskets of groceries waiting for the delivery boy in a grocery store. You see them, but that is all.

Compounds Are All Secret

Ask what this chemical is, ask about that, and the same reply comes, "That is our secret. Our compounds are all secret. We have hundreds of compounds, but no outsider ever gets a glimpse at the compound book."

That is the treasure of the factory. The compound used in this or that tire is just as great a secret as the ingredients and their proportions in some patented liquid. For this compound perhaps five or six high-grade chemists in the experimental department work year in and year out. The improvements in these compounds make the tires good or bad, make them capable of withstanding heat, make them tough, make them flexible, or make them meet any of the demands that the tire maker has to cope with. Each metal box is carefully measured out by weight, just as carefully as your druggist fills the prescription that your doctor gives you. As great accuracy is necessary. Each box bears its ambiguous label, but not even the workmen have any conception as to the proportions of its contents or the value of each in the whole. It is tire mystery, yet tire science, and represents much tire progress.

But these boxes of crude materials are not the only secrets in the tire factory. These masses of crude after having been chewed and re-chewed, ground and re-ground, lacerated and re-lacerated, extenuated and re-extenuated between the giant steel rolls of the calendering machines that are needed just to thoroughly mix the ingredient. Each compound requires its separate mixing, its special treatment.



Left—Firestone hard-base type of solid tire. Left center—Firestone European type of pressed-on tire. Right center—Firestone wired-on tire. Right—Demountable Firestone

These different compounds require more special treatment. Then the tire is put into the vulcanizing wells to be cured. Each compound demands its special treatment. For one compound the temperature in the vulcanizing well is higher than for another. For one an hour may be long enough, for another too long, and for a third too short; so that the innocent trays of the crude materials for the rubber call for special treatment right through the factory. These different compounds are often just as different as grades of iron and require different treatments. They are like different alloy steels: when tempering a chrome alloy it is necessary to bring it to a certain temperature; treating nickel steel calls for a different temperature, treating tungsten still a different, and so with the other kinds of alloy steel.

Compounds are then the great secret in tire progress, and if we were to tell the story of the annual tire model it would be necessary to lay bare the pages of the compound book, and perhaps after doing so few would be much wiser, and if we wanted to break into the inner secrets of the tire concerns to this extent there is not a single factory that would give you the privilege.

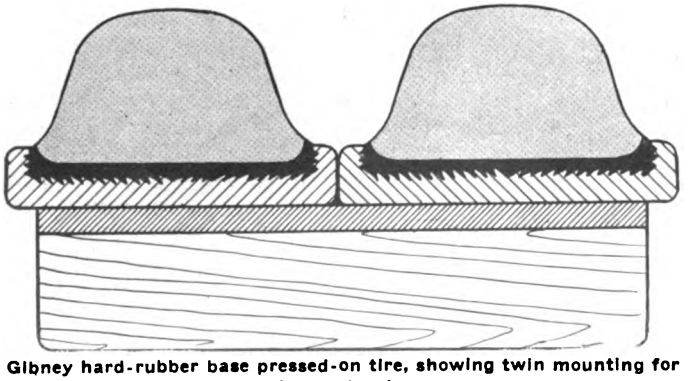
Manufacturing Methods

But tires are not all rubber; there is fabric and there is also the method of bringing the fabric and rubber together—that is, the methods of manufacture. There is sometimes as much mystery about the fabric entering into a tire as there is the compounding of the rubber. Several of the tire factories will not admit you to the rooms where the fabric is inspected and put through its preparation processes. These factories will talk about fabric made from Sea Island products and Egyptian products, and will give you its weight per square unit, but they go further and inspect every strand of it. We all know how to hold our fingers close together between a bright light and our eyes to see the vague skeleton lines. The tire factories require that all fabric pass over rows of electric lights so that inspectors can see every thread, and if there is a broken thread the piece is supposed to be rejected, as a broken thread may mean a premature blow-out.

Lastly the tire maker watches the manufacture of the tire and uses utmost care to see that the layers of fabric, placed one over the other in building up the tire carcass, as they invariably term it in the tire factory, are stretched properly over the mold and at the same tension. To do this the tire-making machine has been developed, and to-day all of our large factories producing tires in quantities of 1000 per day or more use the tire making machine, which is the last word in applying an even tension to the layers of fabric so that the fabric is not under uneven strains and so that there is desired uniformity in all tires.

Machines No Longer Mysteries

These tire making machines for years were shrouded in mystery. Some times they were in locked rooms, with the "No admittance" sign on the door, but of late this mystery has vanished and now you are taken through the tire factory with its special tire making machinery with no more concern than if walking through the machine shop in a large motor car factory.



Gibney hard-rubber base pressed-on tire, showing twin mounting for heavy trucks

Many of the tire making machines are sold on a royalty basis, the tire maker having to pay a certain royalty on each tire built by the machine, the same as is done in the shoe-making field. Not over a dozen of the big tire concerns use these machines, which are of quite different designs, it being almost impossible to recognize scarcely any similarity between a machine of one make and that of another. There is nothing mystifying about them. Building the carcass of a tire is akin to wrapping a bandage around your finger. You start wrapping the bandage one layer over the other and endeavoring to keep the tension about the same, not wrapping one layer very tight and the other loose, but keeping the tension of all the same. Well, in a tire making machine this wrapping is done by the machine. One size of tire may have six layers of the fabric which is impregnated with rubber, another may have seven layers and another may have eight, depending on the size of the tire and the maker.

In wrapping the tire fabric like the bandage on your finger the main difference is that the fabric is wrapped on a metal ring, they call it a core, which is the exact size of the inside of the casing, just the size of the inner tube when in the casing. In wrapping this fabric there are small revolving disks that press the fabric evenly onto the core, making it into the exact form of the casing. After a few layers are on the bead is put on, just a kind of hoop which is placed on each side, and then some more layers are put on and cover the bead.

The great advantage of the tire making machine is that the fabric is always stretched at the same tension, this being done by weights or other combinations. On a tire making machine some of the smaller sizes have the carcass built up at the rate of three every five minutes. The tire is not by any means complete when it comes off the machine, but has to have the tread applied and much trimming and other work done.

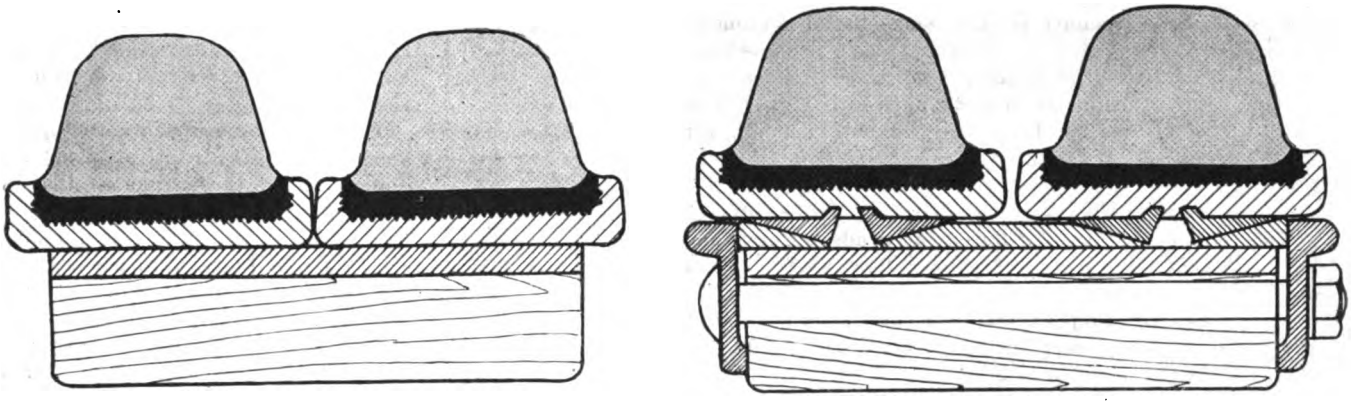
Straight Side Comes to the Front

In the tire world the questions of straight-side, quick-detachable clincher and regular or soft-bead clincher tires are of more or less concern. The straight-side tire is the one without the clincher beads to hold it in the rim. It uses a different style of rim. The quick-detachable clincher is one used on quick-detachable or Q-D rims, which have a removable ring at one side. These tires have the non-extensible bead, that is the bead that cannot be stretched. You could not possibly put this tire on over a clincher rim without the removable side ring. Lastly there is the soft-bead clincher such as used on the Ford car, and other cheap models in which the bead can be stretched so that the tire can be applied over the regular clincher rim.

At present the straight-side tire is making strong gains over the two clincher types excepting in the very low-priced field. One of the largest makers is producing eight times as many straight-side tires as Q-D clinchers, and with many other companies the increase in the use of straight-side types has been very rapid during the last few years. Nearly every tire maker reports large gains in the demand for straight-side types.

There are the usual arguments as to the relative merits of the straight-side and clincher types of tires, but these arguments are not so intense as they were a few years ago, a condition largely due to the gains in the straight-side designs and the fact that practically all manufacturers are building both types according to the respective demands.

So far as price is concerned there is not any difference between one and the other, and when the question of manufacture is considered there is little difference, as the added cost of manufacture in one as compared with the other would



Left—Hard rubber base, and Right—Demountable types of Kelly-Springfield dual solid tires

only be a matter of a few cents which would not matter.

With the car user the straight-side type is attractive, as it is generally conceded to be easier to get on and off the rim. In a canvass of over twenty different tire makers on the relative merits of the straight-side and the clincher types it was generally conceded that there is a somewhat greater air volume in the straight-side type, this increased volume ranging from 5 to 12 per cent or perhaps 15 per cent, depending on the design of casing. Some makers of clincher tires deny that the straight-side type has greater air volume because of the design of their clincher type. Some of the largest tire manufacturers are honestly frank when they say they manufacture both kinds in response to the demand and that they would glady welcome the time when either straight-side or clincher types would be standardized so that it would only be necessary to carry one type in stock, whereas to-day if they have thirty different tire sizes they carry these in both clincher and straight-side types thus doubling the value of stock carried as well as doubling the work of carrying it. Many tire makers are quite settled in their own minds that the straight-side design will be the eventual one and even see the time when the manufacture of the clincher type will be discontinued by a majority.

Cord Tires on Increase

One of the pronounced tire trends of the past year has been the greater volume of cord tires used, cord typifying a form of construction opposed to fabric tires. Goodrich and Goodyear are the great exponents of cord construction to-day, these being the leaders in marketing the cord product, although there are many other concerns that are experimenting with and developing the cord design in one form or another.

Goodrich has been manufacturing the Silvertown cord in quantities, having installed banks of machines by which the tire carcass is built up of two layers of continuous cords laid side by side as closely as thread on a spool, but the arrangement being different. Goodrich has the patents for America for this tire, which is the invention of an American, John Palmer, who now resides in Riverside, a suburb of Chicago, and who is still active in the field of tire invention.

Goodyear has a quite different form of cord tire in which the cords in one layer lie parallel and are so held by fine cross strands, ½ in. apart. These strands permit of the cords being handled the same as a piece of cloth, which in turn enables the company to manufacture its tire practically the same as a fabric tire; whereas the Silvertown cord tire is made by winding a single cord from side to side until you have built up two complete layers, which form the tire carcass. In Goodyear the layers of cord are applied like layers of fabric would be.

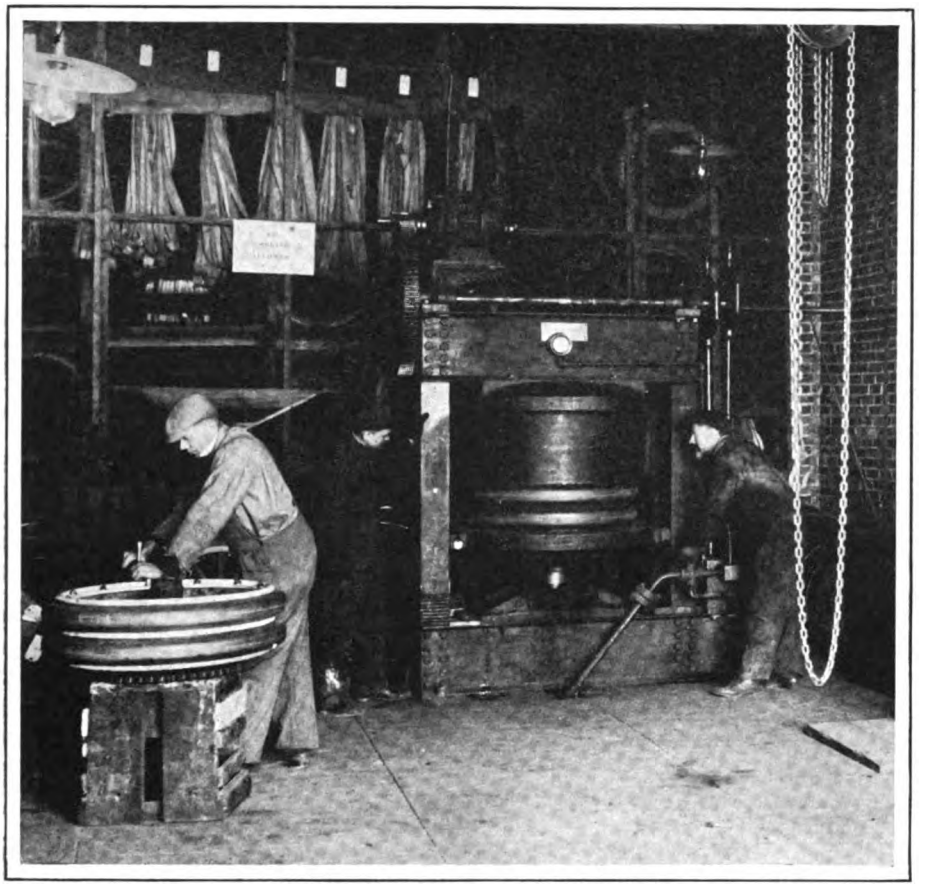
Advantages of Cord Tires

The advantages advanced for cord tire constructions are reduction of vibration, improved coasting, increased speed and reduced gasoline consumption. The theory of explanation is that the cord tire casing is easier to bend or dent when passing over a small obstacle than the fabric, due to the fabric being composed of woven strands lying at right angles to each other, the same as in any woven texture. It requires more pressure to dent such a fabric and consequently more power is required to drive a car over an obstacle. Conversely, when the question of coasting is considered the car coasts further because its coasting is less retarded by passing over obstacles. There are objections, of course, to the use of different forms of cord tires, the objections depending on the form of construction. With some forms of cord tires it is harder to make a repair than with a fabric, it being understood that a cut is a factory repair job, whereas a similar cut in a fabric tire could be repaired as well at a vulcanizing shop as at the factory. The cords used are generally larger than heavy wrapping cord and naturally cutting one is more serious than rupturing a few strands in a woven fabric. Cord tires are considerably higher in price than fabric types, some makes being 40 per cent increase.

The prices on practically all makes of fabric tires are from 14 to 20 per cent lower than they were a year ago, a general reduction having taken place last February. Few decreases have taken place since then. Compared with four years ago the price of tires is 40 per cent lower to-day. The price of crude rubber has been relatively steady during the past year, except soon after the outbreak of the war when the price soared temporarily due to uncertainty regarding shipments of crude from the East Indies and the Straits Settlements, both large producers of crude; in fact, 60 per cent of American crude comes from these sections. There has not been any shortage, and to-day our rubber makers have plenty on hand. Recently England placed an export duty of 2.5 cents per pound on all crude leaving her ports, but that has not resulted in any increase.

Since last spring when Great Britain placed the embargo on crude all of the supply entering America has come consigned to the British Consul General, this being in accordance with a gentlemen's agreement entered into by the American tire makers and the British government. Through the Rubber Club of America, New York, the desired distribution to the different tire companies is effected. The tire companies have agreed to make complete statements regarding articles which are exported, the object of Great Britain being to prevent these articles reaching her belligerent enemies.

To carry this agreement still further the tire makers have agreements with car and truck makers to whom they sell tires, to the effect that all shipments of tires out of the country must be reported and no tires, not even on vehicles are permitted to go to such neutral countries as Norway, Sweden, Denmark, Holland, Switzerland, etc., except by way of England. There have been very few abuses of this working agreement. For a time a few car makers made shipments that were not reported and it looked as if Britain might



Putting on solid tires with a powerful hydraulic press at a Goodrich service station

place restrictions on crude shipments to America, but this has not occurred, and to-day the sky is clear so far as the supply of crude is concerned.

60 to 70 Per Cent of Crude from Far East

At present approximately 60 per cent to 70 per cent of the crude used by the makers comes from the rubber plantations of the East. The remaining 40 per cent comes from the Amazon valley in South America. The crude from the East reaches the factories in a more uniform and workable condition. It is better washed and more quickly and easily handled in the tire factories. The large majority of the plantations in the East Indies are owned and controlled by England. All of it is brought in English boats and it is cleared through the rubber brokers of London. During the war shipments to America have been made easy and simplified since the embargo agreement referred to was made.

The manufacture of the metal rims for pneumatic tires has practically been regulated by the Clincher Automobile Tire Manufacturers' Association, Cleveland, Ohio. This association numbers in its membership nineteen of the largest tire makers, fourteen concerns manufacturing rims, demountable wheels, etc., some of the latter having associate membership only. This association has practically standardized all types of rims such as straight-side, Q-D clincher and regular clincher. These different sizes are illustrated herewith, page 956. Height and width of each only appear as some of the other dimensions have not been entirely agreed upon by the different members of the association. As the illustration shows there is one set of standards for Q-D and clinchers and two distinct standards for straight-side rims, one known as the narrow standard and the other the wide standard. No. 2 is the narrow and No. 3 the wide.

The Clincher Automobile Tire Manufacturers' Association has its inspectors at all factories manufacturing any of these types of rims, whose duties consist of inspecting all rims to see that they are accurately made and also to stamp them with the association's stamp showing that they have been inspected and measure up to the requirements of the association.

Tire manufacturers in turn have set about to manufacture tires to meet the dimensions of these rims so that one make of tire of a given dimension is interchangeable with any other make, in other words if the tires are carefully made one make should fit as well on a standard rim as another make. As the rims used on wire wheels are inspected by the rim association they offer no obstructions to the use of any tire.

Anti-Skid Tires Gain

The use of anti-skid tires is steadily on the increase and new types are being brought out each month or as makers see the demand increase. These are all of the rubber type but with the anti-skid patterns of all kinds. Several rubber makers report that over one-half of their output in the larger sizes are non-skids. One of the last concerns to adopt the rubber anti-skid was the Michelin, that entered the field a few months ago with its Universal tread made for straightside and quick detachable clincher rims. The Universal is a depressed type of non-skid in which it is aimed to combine the features of the suction non-skid as well as that of the raised or studded type, leaving a heavy, broad flat tread on which are two rows of diamond-shaped depressions in the tread with horizontal notches from the diamond to the side of the tire.

While not bringing out anything new in non-skids several tire companies have added slight improvements. Goodyear for several months has been increasing the size of the buttons on its A. W. tread.

Empire is changing the design of its non-skid making the non-skid portion wider and lower, and will bring out a red non-skid cord tire with the same non-skid design as used on its fabric tires. Miller continues its geared-to-the-road non-skid.

The Falls company has nothing new excepting a dead black tread, and expects to add a cord tire during the coming winter. The National company is bringing out a new tire, the Redwall, with a white tread and red side wall. Carspring is making a majority of its tires with non-skid treads and has improved these by slightly altering the bevel of the cups. Globe is now working on a new non-skid. The Mansfield company has a cord tire with its new design of Ohio non-skid.

The Combination Rubber Mfg. Co. will soon bring out its new Hold-On non-skid tire which is a depression type.

The Racine company is manufacturing a cord tire in addition to its horseshoe brand of fabric tires.

Braender has brought out a new model tread during the year known as its new type non-skid. It relies on the hold of arc-shaped cross bars of rubber on the tread as well as the vacuum created in the depressions between these bars.

Hood manufactures two brands of tires, the Hood and Puritan. Hood is in both plain and arrow non-skid treads and the Puritan in plain and gripper treads.

Republic is manufacturing its two non-skid types, the staggard and its newer W-M tread.

Swinehart manufactures a depression type of non-skid, the depression being a series of irregular octagons in the tread.

Hard-Base Solid Tires Gain Followers

AT present one of the most important trends in the solid tire business is that toward the use of the pressed-on tire in preference to the demountable tire. In our larger cities the pressed-on solid tire is gaining, whereas in the smaller outlying cities and towns the demountable tire has the following. The reason is: To remove a pressed-on tire from a truck wheel or put one on a wheel requires a hydraulic press that costs between $500 and $700. This is considerable outlay to the dealer for the amount of work he may get. To make it a little easier some of the tire companies are assisting the dealer by selling these presses at the rate of $100 down and $100 per year until paid for, on the condition that the dealer uses the press only in connection with the make of tire manufactured by that company, although this narrows the field for the dealer.

In small cities and towns the demountable solid tire is looked to to continue in use for some time. From its very nature it can be removed from the wheel and a new one fitted without the truck owner having to take it to a garage. Unfortunately it is more expensive than the pressed-on tire, due to the several forged and rolled steel parts used with it. Practically all of the solid tire makers are continuing their demountable types but the number produced is on the wane.

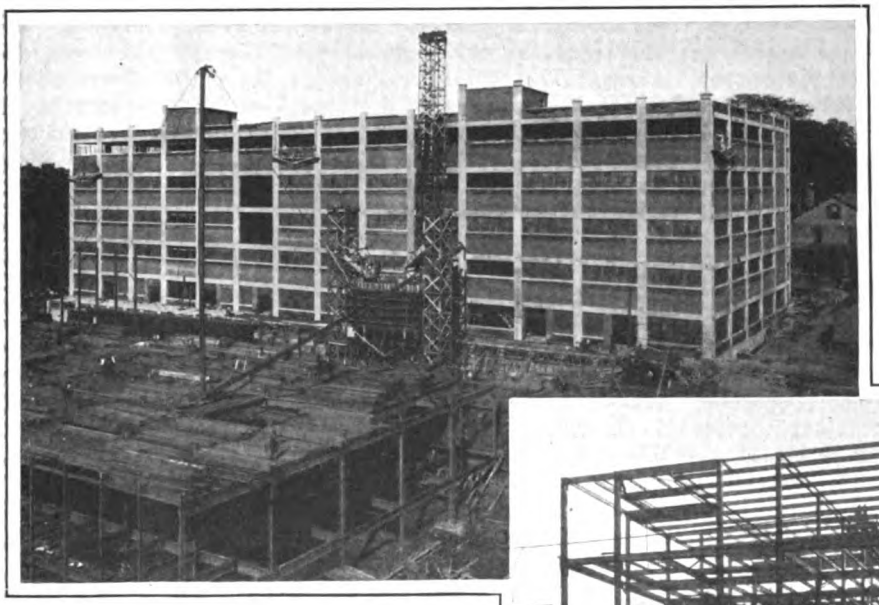
During the past year several movements have been exhibiting themselves in the solid tire field. What is known as the hard-rubber base tire has gained over other types during the year. This tire is built onto the rim in the tire factory and cannot be separated from it. The surface of the rim is cut with grooves, undercut notches or in other ways so that the hard rubber base gets a firm anchorage into the rim. In manufacture this rubber base is applied in some factories in layers just as you wrap a bandage on your finger. The base is relatively thin, perhaps not one-eighth the radial thickness of the tire. On top of this part is built the regular rubber part of the tire, of softer rubber to afford the desired resilience. This part in some factories, is built up just as you wind the bandage on your finger until the desired thickness is obtained, which when done the tire is trimmed to shape and then vulcanized. Thus you see the metal rim is a built in part of the tire. Some of the concerns building this type of tire are Goodrich, Firestone, Goodyear, United States, Republic, Kelly-Springfield, Gibney, Swinehart, Hood, etc.

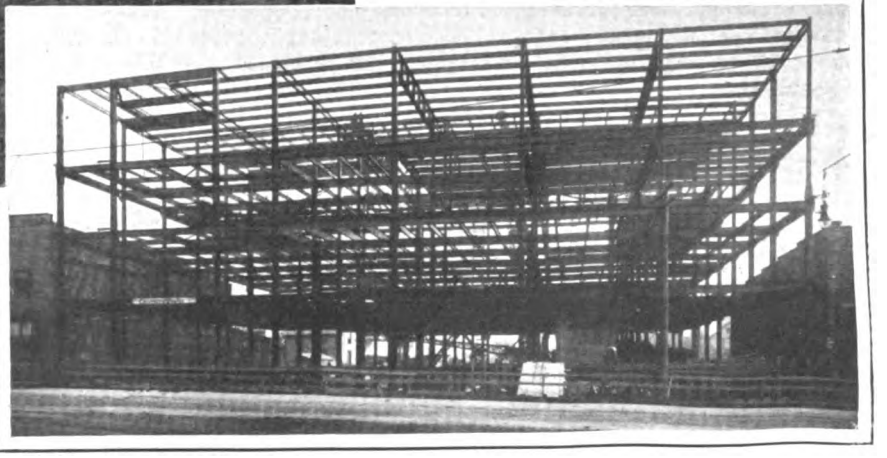
There are other types of solid tires such as the side-wire built by Firestone specially for the smaller sizes. This tire is not manufactured into the rim as is the hard-rubber base type but is afterwards attached to the rim. Into the base of the tire are placed stout cross wires at frequent intervals. When the tire is placed on a channel rim it is held in place by two circumferential wires, one at each side of the tire, these wires resting upon the ends of the cross wires, by virtue of which the tire is retained on the rim. Swinehart manufactures what is called a soft-base tire with cross wires for holding it in the channel rim.

An important movement in solid tires to-day is that of endeavoring to reduce the number of sizes to fourteen if possible. For several years tire makers in connection with the Society of Automobile Engineers have been working on this problem and to-day it looks as if the following will be the eventual sizes for solid tires:

34	in	2.5 in. width
36	these	3 "
40	widths	3.5 "
		4 "
		5 "
		6 "
		7 "

The majority of the tire and truck manufacturers prefer that only the 36- and 40-in. sizes be recognized as standard as they claim 80 per cent and possibly 90 per cent of all solid tires used at present are of these two sizes. There are, however, several makers of small-capacity trucks, 1000 to 2000 lb., who are fitting 34-in. sizes and are to-day making strong arguments to have the 34-in. size made a standard. They claim that the 36-in. size often gives a vehicle with too high a loading platform, as many of this type of vehicle have low platforms.





Above—Fisk's five-story reinforced concrete warehouse nearing completion and showing foundation of new factory building in the foreground. At Right—Steel skeleton of Firestone's new clubhouse for employees. It will have all modern club attractions, including swimming pool, bowling alleys, recreation rooms, restaurant, etc.

These three sizes will be a big improvement as compared with a time ago when solids were made in 32, 34, 36, 38, 40 and 42-in. sizes making in all forty-two different sizes. To-day there are over 150 cities in the country with twenty-five or more motor trucks and the tire depots in these cities in attempting to give the best possible tire service have to carry many slow-moving sizes, which will have to be done for a few years yet, but which work will eventually be much simplified by settling on perhaps two or three different sizes.

Goodrich's New Policy

During the year Goodrich has been promulgating its new policy with regard to single and dual tires for heavier truck work. To-day Goodrich is recommending a 7-in. single in preference to 4-in. duals; 6-in. singles in preference to 3.5-in. duals; and 5-in. singles in preference to 3-in. duals. The arguments are that these singles give better results than the corresponding duals in that often on the road one of the duals has to take the entire weight of load on that wheel and that as it is not designed to take the entire load it is naturally overloaded and perhaps permanently injured by this frequent caring for the entire load weight on the wheel. With singles this is not the case.

Another Goodrich movement of the year is the introduction of the De Luxe type of solid tire in both single and duals. The De Luxe is a higher section tire, one designed after the higher-section tires used in Europe, although the Goodrich uses a quite different contour from the European makers. These Goodrich De Luxes are much thicker radially than their other solid. On a 5-in. size they are 0.75-in. thicker; and on 6- and 7-in. sizes are 1 in. thicker. Greater resilience is claimed as well as longer life and greater load carrying capacity. It has been designed for extra heavy duty and is recommended as an oversize with the same sectional width. The carrying capacity per tire is 500 lb. greater. Hood has introduced higher-section tires during the year.

Firestone has recently introduced what is known as the Giant single solid tire which is made either 8 or 12 in. wide. The extra amount of rubber in this tire is claimed to make it oversize equipment for 6-in. duals and equal equipment for 7-in. duals. The tread has three evenly-spaced circumferential grooves in it.

Tire Factories Leaders in Employees' Welfare

WELFARE work in the factory of the Firestone company, Akron, is being pushed particularly actively at the present time. The company is at present erecting a club adjacent to its factory which measures 125 by 151, four stories in height. The steel construction for this club house is practically completed and the club will be occupied Feb. 1. It is intended solely for the employees of the factory and office. It is expected in the carrying out of the club that each employee will take a membership which may be obtained for a nominal sum, perhaps $1 a year. When finished the club will be very complete. In the basement there will be a tiled swimming pool for the men measuring 60 by 20 ft.; adjacent to this will be twelve showers; and in the remainder of the basement will be six bowling alleys, twelve pool tables and a barber shop.

On the first floor will be a restaurant for the employees with accommodations for 970. The second floor will contain the restaurant for office employees, and will have capacity for 700. On the third floor will be the large club rooms, lounging rooms, library, etc.; and the top floor will be devoted to an assembly room which will be partitioned off into committee rooms, all of which can be thrown into a large assembly auditorium as needed.

In addition to this club work the Firestone factory has its medical department which was started twelve years ago, and which includes, a corps of medical attendants made up of a chief surgeon, resident factory doctor, two trained nurses for day work, one for night work, and a dentist. Arrangements are being made to take blood tests and conduct regular bacteriological analysis. In case of slight injury to employees they are taken to the factory hospital or home.

One of the latest acquisitions to the medical department is the dental office which has been opened in the factory, and which is conducted by a dentist of five years' experience. This department started Sept. 1, and is for the use of all employees in the factory who pay a nominal sum for work done. The factory expects to have all employees' teeth examined once a year.

In the medical department the Firestone company is starting a special series of examinations of all employees with the one thought of determining by accurate physical examination if the employee is physically suited to the job, or if there are other positions in the factory to which he is better adapted. By this department it is discovered, if perhaps, workmen with heart affection are engaged in heavy lifting, which would be dangerous. Such a person would be transferred to some other department.

Goodrich has for many years given very careful attention to its employees, both by means of a well-equipped medical department, to which has been added an efficient dental department, but the latest activity in this factory welfare work is that of installing rest rooms for the female employees of the office, one of which has recently been opened. This is an attractive room in the office building and is well fitted with suitable furniture, rugs, reading tables, etc.

In the medical department Goodrich makes a physical examination of every employee, with the thought of seeing if he is well adapted for the particular work he is doing. These examinations also have a salutary effect, and show the interest the company takes in the welfare of its employees. This department is well manned with resident physicians and nurses. The dental department is for the service of all the employees in factory and office. Tire companies are taking the lead in this welfare work, which must not be considered philanthropic alone, but which at the end of the year shows on the proper side of the ledger. The good health of the employees is a great factor in any factory. Goodrich has a large equipment of restaurants for its employees which are conducted much the same as those in other factories.

Some years ago the Republic company erected its club house for employees which has been operating with particular satisfaction ever since. In addition to bowling alleys, pool tables, gymnasium equipment, restaurant, club rooms, reading rooms, and many other amusements, many educational classes are carried on. The employees in factory and office took readily to the movement which is well patronized throughout the factory. In addition outdoor sports are cultivated.

Practically all of the larger factories are taking up the welfare work with medical attention in the factories. The Pennsylvania company has Paruco Park, the property of the company which is for the use of all its employees. Here is a gun club with a membership of seventy-five members, which requires annual dues of $1. In the factory are shower baths for certain departments, filtered drinking water at numerous fountains and the usual medical and restaurant arrangements.

Kelly-Springfield has carried on special welfare work and has started educational work with its employees. There are reading rooms for foremen and the usual medical attendants.

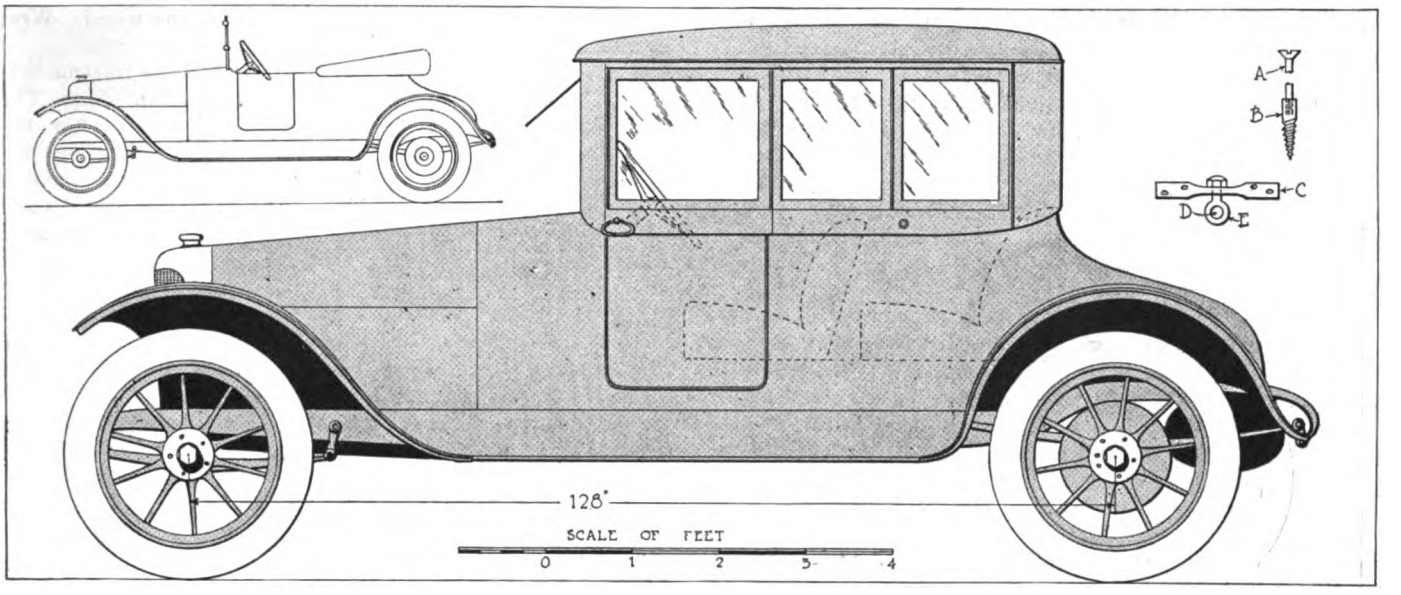


Fig. 1—Center—Apperson four-passenger runabout with suggested design of top added. Fig. 2—Upper Left—The same body with ordinary type of top. Two Demountable Top Designs

Entirely New Type of Body May Evolve from Present Closed Car Development—Types for Apperson Runabout and Chalmers Touring Car Chassis

By George J. Mercer

THE demountable top fitted to touring and runabout bodies is becoming increasingly popular each year, and the coming winter bids fair to outrival in numbers the total output of the past seasons.

The quality of the work and the designing both show improvement, which is no doubt due to the large number of good builders giving their attention to these matters. The demountable top has arrived at the stage where it is accepted as a staple article of manufacture that the public must have. Unquestionably the largest number used will be the type that can be sold complete and assembled on the body, for $75 to $150 as it is for cheapness that the top has come into existence and the majority of buyers are those who expect to economize.

A great range of possibilities is open to the body builder when converting the open body into a closed one. Some use the regular four-bow or the one-man top that is already on the car and simply add side glasses with a framework to hold them in place. In a few designs this addition is made in such a way that the top can be folded down by simply taking out the glass frames. In the majority, however, the entire framework has to be removed in order to fold the top, and this is done only at the beginning and end of the season. There is a considerable increase in the number of car manufacturers who provide a demountable top as regular equipment, and the number will increase in the near future. Eventually a new body design will evolve out of the present efforts.

Novel Body May Evolve

A very good business is being done by individual builders who specialize in converting the bodies in use into closed cars, and this affords a field for all the ingenuity that is latent in the body mechanic. The average body design is stereotyped before the public becomes familiar with it, and the body builder simply makes a copy, taking another body as a model. But supplying the demountable top is a free-for-all race, and it will be strange if in the near future a distinctively novel body is not brought out, that will be as distinctive as was the flush-side body type.

The standard forms of collapsible bodies of the better class, such as the landaulet and the cabriolet, have the distinctive look desired by the buyer who can afford the price, but the full leather top lacks the adaptability that the knockabout car owner needs. A fine carriage body is like a pair of shoes to many people; it only becomes comfortable about the time it is nearly worn out. The rough and ready demountable body, that does not involve the expenditure of much additional money, has the right seasoning to make it popular with a large number of car owners.

All Bodies Easily Converted

There are many manufacturers who are prepared to furnish tops for the standard makes of cars at short notice. They are equipped with forms that correspond with the bodies, and they only require the car, first long enough to check up the measurements, and then later on to assemble the top. All the modern bodies are easily converted, because the trimming roll at the top of the seats does not extend appreciably beyond the body line and the top line of the body is of such a shape that the assembling of the upper framework is not difficult. The worst feature is the adjustment of the hinges, that is, provided hinges are used on the upper part, as most touring doors are made to drop downward when open,

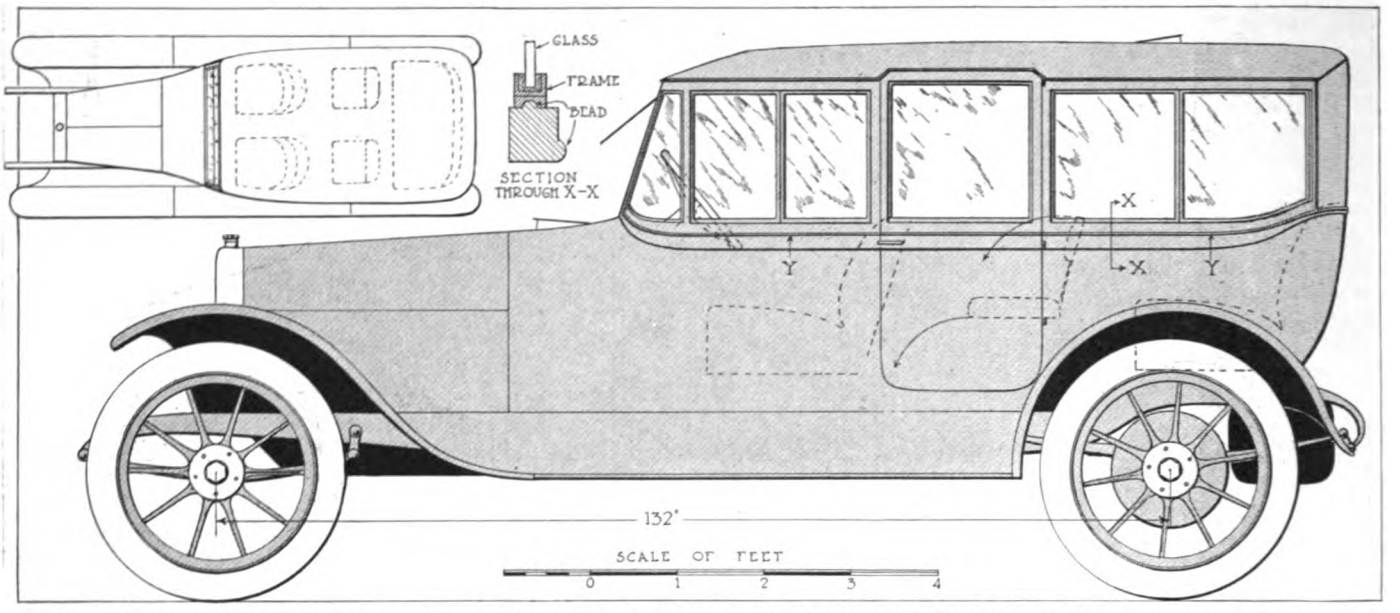

Fig. 5—A demountable top for a seven-passenger Chalmers touring car. Fig. 6—Miniature plan view of this construction, showing how the forward triangular glass is flat and stationary to follow the side sweep of the body toward the front. Fig. 7—X-X—showing how the four glasses on each side of the top are held in place at the bottom. The glasses are metal bound at the top and slide in a groove in the wood top rail, limousine fasteners keeping them tight. Fig. 8—Y-Y—showing the line of separation of top and body. A tee molding covers the joint and the glass side frames are provided with a lip that meshes with its companion glass frame, keeping out the wind and rain

and do not swing horizontally. A great deal of ingenuity has been used to overcome this, some builders making a complete new door that replaces the old one, others placing one long hinge at the top, which projects sufficiently to enable the upper part to swing true with the lower section, but the majority, especially the lower priced designs, do not attempt to have the hinges line; each section has a movement of its own and there is a finger projecting down on the inside of the upper section which engages in a slotted plate on the lower one, this finger traveling in the elongated slide and keeping the two parts in unison when opening and closing, the finger and slot compensating for the different lines of travel. A similar arrangement is made for the lock, the handles in the upper part operating the lock below.

An Apperson Runabout

Fig. 1 shows the Apperson four-passenger runabout with demountable top added and Fig. 2 shows the body without it. To make this top as illustrated, the bow top and the windshield are first taken off and the lower ash rail forming the support for the side glasses is fitted to the shape of the body top line; the rail is cut, part being attached to the door and part to the body and the cut must be made a little back of the door line in order that the part on the door will clear when opening. The jutting out of the added piece beyond the door panel enforces this cut being offset. The side rail continues around the back, the back part not being so deep, and uprights are framed behind the side glass and at each side of the back light; the latter is a separate frame and is screwed to the posts and toprail. The toprail is framed to the posts and the front pillars and the roof is formed with bows, sawed to form the shape of the roof corners, the front pillars are connected at the bottom by a bar that fits close to the cowl panel and the whole front is fastened by irons that engage in the sockets formerly used for supporting the windshield.

Framework Is Light

All the framework is light except the front pillars, and these must be wide to fill the space from the door to the windshield supports. The side glass frames are wood, 11/16 in. thick, and they are held in place at the bottom by resting over a bead, in the manner illustrated in Fig. 7, section *X-X*, the wood frame being grooved to do the same duty as the metal frame in the illustration. This bead keeps the rain from entering and at the top the glass frame rests in a rabbet in the toprail, the rabbet being open toward the inside. There are two limousine window fasteners for each frame, to remove or place the glass frames in position and the fasteners are screwed back until the frame tilts sufficiently to allow it to be lifted over the bead at the bottom. On the rear, the vertical edge of the door glass frame and the one directly back of the door, tee molding is fastened to cover the openings between the frames and at the rear of the third side frame; a rabbet in the post covers the opening, while at the front the pillar has a regular door rabbet. There is no framing between the front and rear side pillars and, when desired, all the side can be open, the four frames can be stored under the seat and the door glass frame is made to be turned down inside the door. The hinges for turning this frame down are placed inside with the centers on line with the bottom of the frame. When up, it is held stationary by two set screws that, passing through plates on the inside of the door top frame, engage in lugs projecting from the under edge of the frame that enter slotted plates on the top face of the framework.

Original Hinges Used

This glass frame forms the upper part of the door, it strikes against rubber bumpers on the toprail rabbet when closed and there are no other turning hinges used than originally are on the job. It projects back of the door line at the rear enough to line up with the line of cut in the framing, and at the front of it is back of the door line enough to give door bevel, so that it will clear when the door is opened and the frame is down. Also the hinge on the frame is long enough so that space is left between the frame and door to permit free operation of the link connecting the door handle in the framework to the handle of the lock.

The front windshield is in two parts; the upper is a visor and the lower swings inward for ventilation; the back light is square cornered and 13 in. high by 24 in. long is the maximum size, though it can be as much smaller as desired, the glass in this being stationary.

The roof can be all metal covered, or metal can be used to form the rounded corners and canvas or top cloth of any waterproof variety stretched over this and fastened under the moldings. The back panel will be metal also, while the lower side framing and front pillars will be painted wood.

Attaching the framework to the body in a manner that will leave few or no blemishes when the top is removed requires careful planning. Advantage is taken of the regular body top irons on the job to do most of the work of fastening as there are always four and sometimes more. In this case, the forward ones are quite long, and a cap is shown covering this. Diagrams *C*, *D* and *E*, Fig. 3, show how the supports are used; *D* is the gooseneck on the body, *E* is an eye bolt that slips over *D* and the end engages in a hole in plate *C* which is fastened to the upper framework. When assembling, the top is down until the four bolts *E* enter the plates *C* and the nut is tightened until *C* rests on the shoulder of the bolt. These bolts take care of the rear, of the top, and the trimming is left loose at these points so that the nuts can be turned up from the inside.

Forward of these supports, and on the doors, *A* and *B*, Fig. 4, are used. *B* is a lag screw with the head cut off, drilled and tapped to receive a 12-24 machine screw, and a sufficient number of the screws *B* are set in the top framing of the body and door, the top of the bolt coming flush with the finish molding.

The upper framing is carefully fitted to the body line, the holes in the bolts *B* located and the framing is bored and countersunk for the screws *A*. When the framing is very deep *A* and *B* will not suffice and, in addition, angle irons are used with one leg screwed to the under side of the framing and the other extending down inside the body. Screws are put through the trimming into the body frame and finish screws are put in all screw holes when the top is removed, this being also done with the screws *B*.

On a Chalmers Touring Car Chassis

Fig. 5 is a large seven-passenger touring body mounted on a Chalmers 132-in. wheelbase chassis and the top is modeled from the lines of the Brewster sedan. The door for this job is the same as for a closed body; it is in one with the top and the glass is made to drop into pillar slides and entirely disappear. The forward triangular glass is flat and stationary, pointing in toward the front, in order to follow the side sweep of the body as indicated on the miniature plan view, Fig. 6. This view also clearly indicates the shape of the windshield glass.

The other four glasses on each side are held in place at the bottom as indicated by the diagram *X-X*, Fig. 7. The glasses are metal bound at the top and slide in a groove in the wood toprail, while limousine fasteners keep them tight. They are placed in position by sliding in from the doorway, the posts at the front and rear of the door being made with an outer and inner member, the space between allowing the glass frame to enter. When not required, these four side glasses are taken out and stored under the seat, or one can be taken out to give extra ventilation and the companion glass can be pushed forward or back to control the air currents. As before mentioned, the door glass drops and is guided by a lift strap. This glass is frameless. The front windshield has the vision, the lower part is stationary, the ventilator in the cowl compensates for a moving lower windshield and there is also a ventilator in the roof. The back light is stationary.

Framing Up the Top

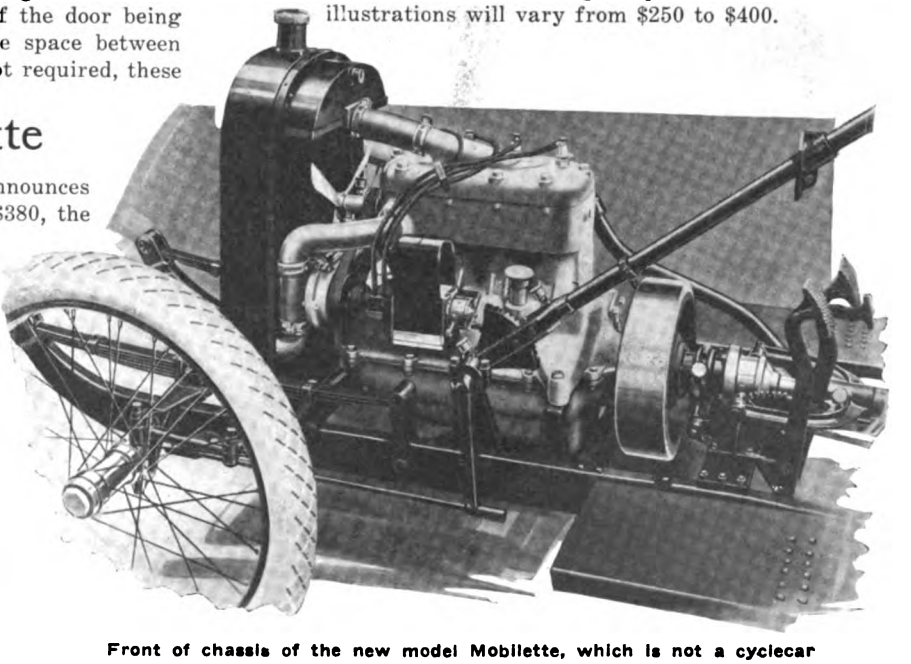
The method of framing up this top is identical with that described for Fig. 1. The line of separation of top and body is on line *Y-Y*, Fig. 5, a tee molding covers the joint, and the side glass frames are provided with a lip that meshes with its companion glass frame. This keeps out the wind and rain where the two frames join in the middle to form the sides at the back and front of the door. The same method of fastening is also used for top and body as shown in Fig. 1, and the door, being made for the purpose, has the lock handle in line to operate the lock without connecting links. The back panel is sheet aluminum in one piece from side window to side window; the roof can be of the same, or the round of the roof can be formed of metal as far up on the roof as where the radius of the corner starts, and then canvas or waterproof top material can be either drawn over the whole roof from side to side and fastened under the drip moldings, or the metal corners can be finished to paint and the roof cloth can form the center deck of the roof, being fastened under moldings running from back to front along the inner edges of the metal forming the corners.

The popular color for painting for the Brewster sedan is the color generally called battleship gray, and the finish is dull, while the part that here is designated as the demountable roof, would all be finished dull painted inside with no trimming of any description showing above the waist line, or the line that corresponds with the top of the seat back trimming, when painted inside. All the woodwork, such as the bows, etc., is nicely rounded and the framing shows very light in size. For Fig. 1, a suggestion for trimming that is commonly used is to cover the seats and backs, which are of leather, with slip linings and line the top with a similar material, this making a uniform appearance inside the body which is not too expensive.

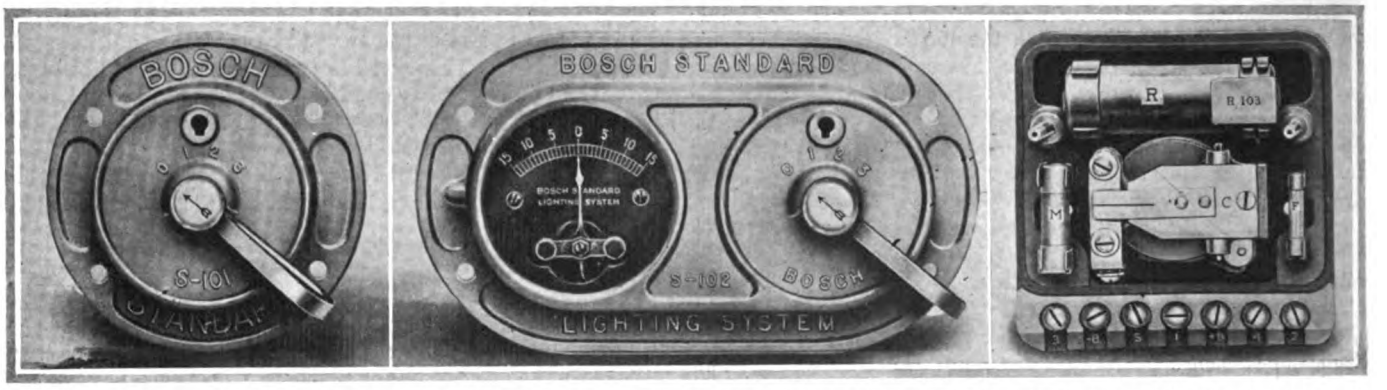
These two designs are drawn to scale and there is sufficient information conveyed to enable the top maker to duplicate them full size. The cost of making a top from either of these illustrations will vary from $250 to $400.

New Model Mobilette

THE Woods Mobilette Co., Chicago, Ill., announces a 1916 model Mobilette that sells for $380, the design being much the same as for the last model, but with a number of refinements. With a 104-in. wheelbase and 36-in. tread the little car is well proportioned. It has a neat four-cylinder engine 2⅝ by 4 in. bore and stroke, with a detachable head. Drive is through a leather cone clutch to a driveshaft with one universal and the gearset is integral with the floating rear axle. Ignition is by Bosch magneto. Two speeds and reverse are given. A feature is the underslung suspension of the front portion of the car, this being shown in the illustration, but the rear axle lies below the frame in the usual way, being attached to a pair of three-quarter springs. Seats are slightly staggered.



Front of chassis of the new model Mobilette, which is not a cyclecar



The switch of the new Bosch Standard lighting equipment combines an ammeter and full control for all circuits, while the switch can be locked. The cut-out, fuses and regulating ballast coil are in a separate box

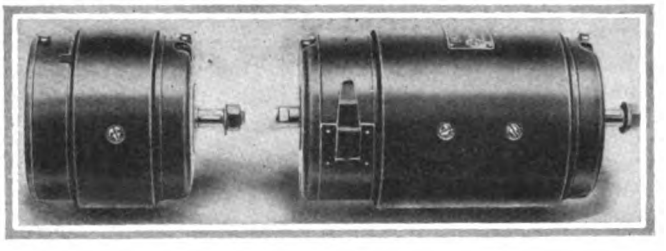
New Bosch Standard Lighting Outfit

Generator in Two Sizes and Has Control for Any Lamps or Starting Motor — Is 12 Volt System

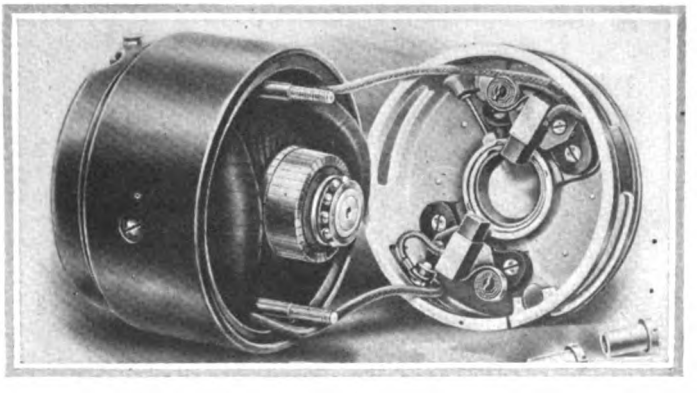
THE Bosch De Luxe equipment which has been known for some time has been supplied only in complete form with lamps and all accessories also of Bosch manufacture, and the purpose of the new generators is to suit manufacturers who do not necessarily desire to change equipment while wishing to employ a Bosch dynamo. The two models of the new type will be known as DSR3 and DSR103, the first being rated at 100 watts and the second at 80 watts. Each equipment consists of dynamo, control box and switch, making three units, and a battery, making the fourth, is necessary to control the voltage of the dynamo.

Inherent Regulation

For regulating the output of the generator the field magnets carry an additional winding which opposes the main winding, the amount of current flowing in these opposition coils being regulated by a resistance coil. If the speed of the dynamo increases and the current output rises, this affects the controlling resistance in such a way as to send current through the opposing winding on the magnets. This in turn, cuts down the strength of the field and so the current, thus returning things to normal.



The casing of the new Bosch generators are made from a piece of solid drawn steel tube and the machine is practically dust proof



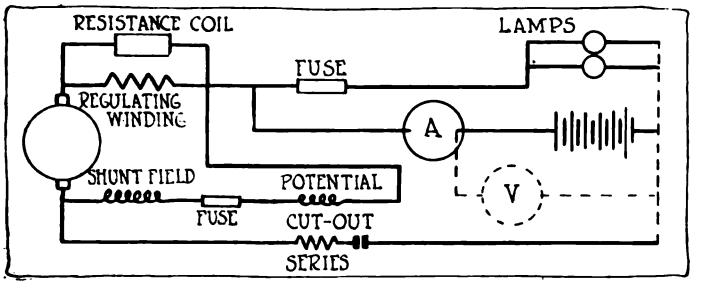
Showing the nature of the brush gear and the method for obtaining access to the brushes

The voltage is therefore determined by the battery, for as soon as the potential difference between the poles of the generator rises above the voltage of the battery when fully charged, the resistance comes into play and sends a restraining current through the field coils in opposition to the main shunt windings. Bosch Standard generators are designed to operate in conjunction with a 12-volt storage battery. It is claimed that the current capacity of the generator is sufficient to care for the full lamp load on an ordinary car, and the battery is needed only for starting or for lights when the engine is not running. The generator is mechanically of extremely neat exterior being sheathed in seamless steel tubing to which a pair of end caps are bolted after everything else is assembled. These caps are secured by a pair of long bolts passing from end to end, inside, so the generator is practically dirt proof.

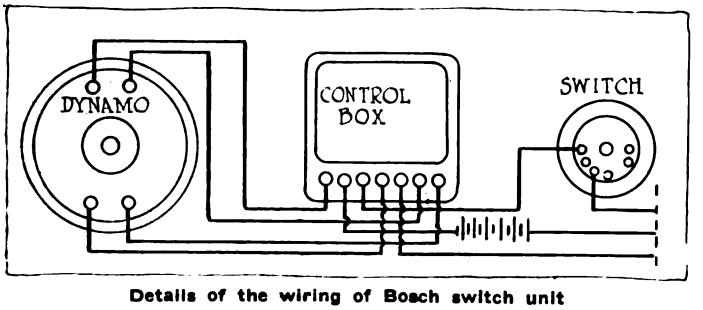
The armature is laminated and is almost entirely encircled by the windings on the two field poles, a feature of design that tends to reduce commutator sparking by damping out armature reactions. There are two brushes, mounted in strong spring holders within the commutator end cap, where they are well protected, and yet readily accessible for inspection as there is an opening of good size that may be uncovered by moving a strap which is held over the orifice by a special catch. To prevent any risk of current loss between the carbon of the actual brush and the clip which holds it, each brush is provided with a flexible conducting cable which goes direct to the terminal.

There are four external terminals, placed in the shaft end cap of the generator and these are clearly numbered, magneto fashion, so that there can be no mistake in making the connections to the external circuits which are shown in the diagram.

The controlling resistance coil and the automatic cut out are assembled in a separate small box together with the main fuse and a field fuse which latter prevents damage to the field coils should the battery become disconnected and voltage



General diagram of the complete Bosch Standard wiring system



Details of the wiring of Bosch switch unit

regulation consequently cease. The cut-out, etc., are accessible by removing the metal cover of the box which can be accomplished by unscrewing two cap nuts.

A remarkable feature of this new system is that it can be used either grounded, for a single wire layout, or with a double wiring system. The switch, which makes the third unit, combines an ammeter and ignition control for the magneto and has four positions, the first is "off" with both ignition and generator out. The second turns on both circuits, the third cuts in the tail and side lamps and the last adds the head lamps instead of the side lamps. The switch box is an extremely neat and ornamental unit in which compactness is marked and would normally be a cowl board fitting, of course.

Although, as stated before, the Bosch Standard equipment will be supplied in the form of the three units, generator, controller box and switch unit, for use with any accessories, the Bosch Magneto Co. will be prepared to supply complete sets of lamps, starting motor, battery, etc., if desired. A feature of all Bosch products is the high finish of every detail, and this will, of course, be maintained in the new equipment, both with respect to internal detail and outside appearance.

New Heinze System

Generator Has Integral Ignition Unit on Armature Shaft

A NEW electrical equipment announced by the J. O. Heinze Co., Springfield, Ohio, is to be made in either single or two-unit form and has for its principal feature the combination of an ignition unit with the generator. The end of the generator is made up with a magneto type of distributer and the breaker cam mounted upon the armature shaft. All this ignition portion is removable and can be cleaned or adjusted with great facility in consequence.

For regulation of the generator output a vibrating reed is employed, this system permitting a tapered charge to be given the battery, a very large current if the battery is low, and a small supply when the battery is fully charged. The machines operate at 6 volts.

For the starting motor a Bendix pinion is supplied for flywheel engagement and it is stated that the electrical design of the motor is such that it produces a large torque with less current than usual.

Special pains have been taken with the design of the switch unit, one lever controlling all circuits and giving various lighting combinations while the starting control consists of a button set in the center of the switch. A lock is provided whereby the switch can be secured in the "off" position.

Stress is laid upon the quality of materials employed, it being the makers' claim that by designing and selecting iron with the greatest care they have been able to produce a machine of high efficiency and low weight. Also the construction has been simplified so as to make possible rapid and inexpensive production without losing any of the high quality desired. As can be seen from the illustrations, the machines have a neat exterior with the square section customary on four-pole types.

The factory has been prepared for the production of the new models with accuracy of workmanship as the goal, and it is stated that the inspection, both of details and of the complete machines is exceptionally careful. Each equipment is to be given an exhaustive running test.

The FORVM

ANOTHER PLEA FOR THE METRIC SYSTEM OF WEIGHTS & MEASURES —AMERICAN LEADERSHIP IN THE PISTON FIELD—ADVANTAGES OF AMERICAN ALUMINUM ALLOYS COMPARED WITH EUROPEAN

Advantages of Metric System

Details Worthy of Present Study Because of War Conditions

By Charles Vivier

EDITOR THE AUTOMOBILE:—The large volume of foreign business now being done by American firms in exportation of engineering products to Europe turns attention upon the metric system of measurement and makes it necessary for engineers to familiarize themselves more closely with its detail.

The average American reader has had ample opportunity, in the last few years, to observe that various measurements, especially in mechanical and scientific matters, are being given in ever increasing frequency in metric figures. Of late, with the European war, we not only hear of the horrible battle reports, but also our ears are dinned by the continuous sounds of millimeters, centimeters, meters, etc., the terms most commonly used in the metric system. Of all the numerous nations now engaged at war, England is the only one which has not yet adopted the metric system; in fact, the English speaking countries are the only ones which are not yet enjoying its benefits.

The American public should endeavor to familiarize itself as much as possible with the metric system, even if its inevitable adoption by this country is not yet near. The American invasion of metric terms is growing at such a rapid rate that it is obviously to our advantage thoroughly to get acquainted with the new intruders.

Some Special Points of Value

I will not attempt to give a complete description of the metric system; a good many text books have it. I only propose to bring out a few of its wonderful qualities. The fundamental unit of the metric or decimal system is the meter (Greek, "metron"-measure). It is decimal because every single unit is ten, or a multiple of ten, times larger or smaller than its neighbor unit. Therefore, the metric system follows faithfully the fundamental laws of our present universal system of numeration. Let us not overlook the above important fact. This is indeed simplicity reduced to its minutest expression. The direct result is that metric measures can be so easily remembered and compared; that metric calculations can be simply and rapidly made; that metric standards can be unequivocably and permanently created. A school child eight years old can without effort remember the whole metric line; how many grown Americans know the exact number of feet in a mile, how many square feet in one acre?

Starting from the unit, in numeration, we count up to 10; we do not arbitrarily stop at 12, or at 16, or at 64; if we did, we would hopelessly complicate our system of numeration. The American system of measures is confusing purely and simply because it deviates from the law of ten; because it is not decimal. If we insist upon dividing the units into ½, ¼, ⅛, 1/64, etc., instead of tenths, we get badly tangled up and have to suffer therefrom.

Interchangeability of Metric Units

The metric system is so perfect that even Sweden and Germany, the countries par excellence of rigorous mathematics, could not find room for improvements, and they adopted it without hesitation or reserve. Another splendid quality of the metric system lies in the fact that its various branches harmoniously correspond with each other; for instance, one cubic meter weighs exactly 1 ton, 1 liter (1 cubic decimeter) weighs 1 kg., etc. It also offers an easy choice of any unit such as most suitable for the requirements; for example, the millimeter will be chosen for small measurements as the bore and stroke of a gasoline motor, or for the bore of small firearms; the liter will be chosen for measuring the contents of an ordinary barrel, and so on.

Once the metric system was made known to the world, all nations had equal opportunities to welcome it; those with fortunate foresight adopted it at the psychological moment, that is before the enormous industrial development of the last fifty years. England with its customary apathy toward any idea of foreign origin, stubbornly refused its adoption. But of late the metric system has made great strides in the British Isles; the European war, with its vast possibilities of sweeping changes and reforms, may hasten its introduction into the United Kingdom.

For some unexplained reasons, the United States failed to adopt the metric system at the opportune moment, in the meantime, the clumsiness and unreliability of our actual system is being felt in direct proportion to the development of our trades and industries. Compared with the metric system, ours seems ridiculously antiquated. Our present needs demand a reliable measuring system; we also realize that the remedy for the trouble is very close at hand, yet we seem quite willing to get along with the old-fashioned tallow candle instead of the nitrogen electric light.

Difficulty of Change Increasing

On several occasions, the question of the probable introduction of the metric system into this country came up seriously, but each time the difficulties of the change loomed up so enormously great that the attempts were given up at their very inception. These difficulties are not unsurmountable. It is true that some of the European countries had some trouble in changing systems because some of their stubborn citizens insisted upon using the old measures; such trouble could not be experienced here because of the true up-to-dateness of the American public. We must not worry about the past, but rather about the future; our next generation needs a reliable measuring system, and we can afford to inconvenience ourselves a little now, especially so because the delay is making matters rapidly worse. The parcel-post and the federal reserve bank laws made a few malcontents, yet their value to the American nation is inestimable.

It must be admitted that the task of making the change of systems in this country would meet prodigious obstacles. In

addition to a considerable federal appropriation, the appointments of scientific commissions, etc., the opinion and suggestions of the greatest American manufacturers and economists would prove the most important factors in the proposed reform, which, if intelligently and gradually applied, could take place in a surprisingly short time.

Once the metric system is solidly implanted here, it would then be a favorable time to think about finishing up a few minor details like the adoption of the Centigrade thermometer and the final internationalization of the standards of mechanical and electrical power which are now badly intermixed with metric and old figures. For an ideal unit of power, we should greatly favor 1 hp. = 100 kilogrameters-second, a well defined amount of energy, also a unit of power lending itself nicely to our present mechanical needs. It would be a comparatively easy matter, after a rational altering of the old electrical units, to make the kilowatt equal to the above mentioned new horsepower.

In conclusion, let it be known that the metric system is the most remarkable heritage of the French revolution of 1789, which abolished the ancient régime and the slavery in the French colonies. Among the many badly needed reforms, the newly-born French Republic was quite prompt to realize the necessity of a reliable system of weights and measures.

American Alloys Best

By Joseph Leopold

Engineer Walker M. Levett Co.

EDITOR THE AUTOMOBILE:—Continuing our well advanced discussion on the subject of aluminum pistons, it appears that there are still existing several skeptics who are not fully convinced that the aluminum alloy piston has long since passed the débutante stage and is now a product for standard production. It is my opinion—and I am not alone in this conviction—that the remaining skeptics are against the aluminum alloy piston solely because they have failed to come into contact with a reliable and improved mixture. As Mr. Sherbondy points out in his last article, the alloy piston was experimented upon by European engineers several years ago, but did not prove to be worthy of anything more than superficial consideration. May I not suggest here that the alloy experimented with was not what good aluminum alloy is at the present time? I do not believe it exactly fair to condemn aluminum alloy pistons in general, for the reason that *some* have failed to produce results. It would seem to me that America deserves that much more credit for producing an alloy which can show unfailing results. As pointed out in one of my former articles, before the war we were importing a metal from Germany by the name of magnalium, which metal I believe was used almost exclusively for alloy piston construction in Europe. Inasmuch as we were then unable to obtain a further supply, we were thrown upon our own resources to produce a metal in substitution—and luckily too—for we produced an alloy which showed a greater tensile strength and improved physical properties throughout.

Mr. Sherbondy's latest treatise—Analyzing Heat Flow—creates the impression that the American engineer is too hasty; that he has accepted the aluminum alloy piston on the strength of superficial considerations without regard to engineering value; that he has merely followed the crowd, disregarding logic; and that he is inferior to the European engineer in so far as originality, initiative and independence of thought are concerned. The Peugeot and several other cars were then cited as examples of superiority. In refutation of this assertion, I beg to refer to the recent Astor Cup Race, held at the Sheepshead Bay Track, in which five Peugeot cars started. It is my impression that these automobiles were constructed to the limit of European engineering skill—although they were perhaps handicapped by the war—but, as we all know, not one of them survived the race. If we trace the cause of trouble it leads us in the majority of cases to connecting-rod fracture and collapse; and if we investigate a trifle further we may arrive at the conclusion that piston construction was at the root of the whole difficulty.

American Engineers' Progress

Let us now consider the product of the American engineer—the Stutz cars which were first and second and the Duesenbergs finishing third and fourth. These automobiles were equipped with aluminum alloy pistons—the product of American manufacture—and yet they put all former records for the distance to shame. It may also be opportune at this moment to note that American cars hold first, second and third places for the racing season of the year 1915, all of which were equipped with aluminum alloy pistons. It appears to the writer that a more severe test could not be performed, and consequently the opinion is created that the American engineer is fast approaching the mark set by the European engineer.

Concerning Mr. Sherbondy's thermo-dynamic treatise; I concede that the theory advanced is not questioned, nor were my intentions ever to dispute it as it is now related, but quite unfortunately theory may not always be combined successfully with practice, and it is therefore mandatory that we consider actualities at this time, rather than mental conceptions, since the aluminum alloy piston has outgrown its embryonic period of progression. If I remember correctly, Mr. Diamond pointed out that a perfect oil film between the piston and the cylinder wall is non-existent, and in this event metallic contact between the cylinder wall and the piston would be prevalent. Consequently the method pursued for heat disposal would be that of conduction, and not convexion in so far as concern is permitted this factor.

With reference to accounting as negligible the heat given up by radiation in the piston, I beg to disagree, as I have ascertained by actual test that a ribbed head piston throws out its accumulated heat much more rapidly than a plain head piston. This theory is best substantiated by the practice of constructing a series of flanges on air-cooled cylinders, and the fact that a greater cooling area is exposed to the air.

Vibration and Fuel Consumption Factors

In reviewing Mr. Sherbondy's conclusions as to inertia force, I notice some intimation as conceding that same is of some importance, although it is stated negligible as far as commercial production is concerned. The paramount point which may be tendered to uphold the aluminum alloy piston in the respect of commercial production is the fact that vibration is reduced and fuel economy affected, even if high speed is not taken into consideration. The latter mentioned, however, is inevitable in the future design of motor vehicles.

Consider the Service Station!

Automobilists do not seem to realize the importance of planning ahead for their repairs and adjustments. The majority of work done on a car might just as well be done next week as last week. However, many motorists make the mistake of dropping into the service station unexpectedly and insisting that the car be done by a certain time. Often these demands work no hardship because the shop is slack but just as often, the shop is already overloaded with work, and additional customers mean overtime work.

The History of the American Automobile Industry—5

Further Development of Steam Carriages—Public Prejudice Against Them—First Applications of Steam and Other Motor Power to Bicycles—Gas Engine Makes Progress

By David Beecroft

¶ Review—Last week the development of the electric vehicle was traced from 1800 to 1880, which year marked the beginning of the present practical era. This account also dealt with the application of electric power to boats and for other purposes, including the first street cars, running in 1832. It was in 1837 that hot tube ignition, which in later years found very extended use, was brought out. A patent taken out in 1844 embodied a number of valuable features, among which were the use of liquid fuels, a type of carbureter, compression of the fuel, flame ignition, air cooling and a clutch. Armored cars were mentioned at the time of the Civil War, a matter of interest in view of their practical development and use in the great European conflict now being waged. This week further developments in the application of steam to carriages, velocipedes and bicycles are taken up and the growing interest in the problem of self-propelled vehicles outlined.

ALTHOUGH the Civil War called American energy into other lines, the automobile idea did not wholly die, but was kept alive by several inventors. One of these was the well-known steam engineer, Sylvester H. Roper, 1826-1899, who began his various experiments as early as 1859. Until his death in May, 1899, he never wholly ceased this work, doing a mile on the Charles River track, Boston, Mass., in slightly over 2 min. on his latest model motor bicycle. While his preference seems to have been steam, he also built a four-wheeled vehicle driven by a hot-air engine, and later a four-wheeled steam buggy. During the velocipede craze of the later sixties, he fitted several of these with steam motors. Roper's persistence as well as his reputation did much to educate New England people to the steam vehicle, and the ready acceptance of the little steam cars about the time of his death can undoubtedly be partly ascribed to the educational work done by him. His last steam buggy was sold to William Holmes, a prominent brick maker of Boston, in 1894.

Roper's Steam Carriage

Roper's steam vehicle of 1863 seems to have been a conventional four-wheeled carriage for two passengers driven by a 16-in. boiler and having a water tank at the rear. The engine was of about 2 hp. and coal for the day's use was carried under the seat, the estimated cost being about 1 cent per mile for fuel; 15 to 20 lb. of steam are said to have been sufficient to operate, but more could be used, 60 lb. being mentioned in one description. The weight was 650 to 700 lb. and speeds up to 20 miles per hour possible. It will thus be seen that this vehicle was a very excellent construction, considering the time when it was made and that its influence shows very plainly in the steam vehicles brought out over 30 years later.

Public Against Steam Carriages

It may seem queer to our readers that with such light construction and such evident practicability as some of these steam carriages of this period showed, they did not win recognition and become a commercial success. The comments of the *Scientific American* editor in January, 1865, throw light on this matter. He says: "Public opinion is against the steam road carriage. Many have been made, but those existing and in use can be counted on one's fingers." He mentions the effect of the continuous jarring, although why a light carriage driven by a two-cylinder steam engine, such as Roper used, should jar as much as a carriage drawn by a horse feels the jerky stepping of the horse, he did not explain. He adds that they will never come into common use and could not be practical unless one was willing to be one's "own engineer and repairer." His conclusion, and, doubtless that of many others, was that the mechanical road carriage was a "long way off." In this he proved correct, but not because of the inability of mechanics to build a satisfactory carriage. Public opinion, still strong 25 years later, was at fault and much educating is even to-day required to get new things accepted, regardless of how good they are. Verily, we need open minds.

Another New England inventor by the name of Spencer made one or more steam carriages about 1863 or 1864, and ran them on public streets and highways. About 1868 W. W. Austin of Lowell, Mass., built a light steam vehicle which he drove about the country for several years while exhibiting it. The boiler was horizontal and placed lengthwise of the vehicle, which was of steel. The weight of the boiler was slightly under 100 lb. and hard coal was used for fuel. It is said that "a few cents' worth went a long way."

A Steam Man

A fantastic attempt which displays rather more ingenuity than good mechanical judgment is shown by United States patents to Z. P. Dederick and I. Grass of Newark, N. J., in 1868, covering a

steam man attached to the thills of a wagon and supported thereby while he pulled it along the road. A steering wheel and also a controlling wheel permitted the man to be guided and controlled. Some of our older readers will doubtless remember having seen this mechanical curiosity. When seen by Charles E. Duryea, the man was supported by an arm projecting horizontally from the center pole of a show tent, around which he walked when started. Other than as a curiosity and as an example of a light high-speed steam engine, and an ingenious application thereof, the device had no practical value, but its exhibition in many places did emphasize light steam engine construction. So fast did the engine run that it advertised itself by a musical hum.

Large Demand for Power

The rapidly growing Central West was developing a large demand for power since heat and water power were not available as in the more mountainous and wooded East, and this demand undoubtedly stimulated engine experimenters to produce simpler and better forms of engines without which the automobile was not possible.

$5,000 for an Iron Horse

This demand was quite generally felt and inventors very naturally responded to the best of their ability. Just the form of vehicle demanded was not clear. The horse being the accepted motor was naturally the suggestion followed by some. The president of a Philadelphia street railway company offered $5,000 for an iron horse that might be used as a substitute for the street car horse. That he really expected the device to look like a horse may not be true, but the publication of this offer in the journals of 1875 substantiated this thought. Coupled with this was another thought that anything odd scared horses, and many inventors attempted to lessen this feature by making the device resemble a horse as nearly as possible. Many vehicles were constructed and several patents issued, showing horse-like structures, propelled by leg movement, and also mounted on wheels, which wheels were driven in the more common manner. Not only was this true in America, but also abroad, two steam horses being shown in France in 1875.

$10,000 for a Practical Road Vehicle

So important did this need for mechanical traction seem to be that the Wisconsin Legislature voted an award of $10,000 to be given to the inventor who should demonstrate by a 5-year test that his vehicle could traverse common roads in a really practical manner. When the road conditions then exisiting in Wisconsin are considered, it will be seen that this reward was pitifully inadequate, but it undoubtedly did much to stimulate mechanical activity along this line.

Some people protested against raising the hopes of poor inventors who had no real knowledge of the problem, which was thought by many to be unsolvable, but the offer probably did more good than harm, although its conditions were so severe that its time limit expired before the practical vehicle appeared.

H. S. Taylor of Derby Line, Vt., was a very intelligent experimenter who finally gave up the problem because the power required seemed so greatly in excess of the results to be gained. He had not only watched the experiments of others, but had made in 1876 one vehicle at least, driven by steam, which was as light as 500 lb. His conclusion after having tried so light a vehicle, points very plainly to the fact that the roads were not yet good enough for success, and he did not see any way, with the materials and the mechanical experience then available, to make the vehicle overcome the road difficulties.

So fully recognized was this demand for power road vehicles that the Franklin Institute, aiming to lead in scientific matters, published early in 1876 an article in which it strongly advocated the use of steam carriages.

Interest in Problem Grows

Another manifestation of the growing interest in things mechanical, which resulted in an enormous dissemination of mechanical knowledge, was the Centennial Exposition held at Philadelphia in 1876, in commemoration of our country's first century. No better index of this mechanical growth exists than that shown by the records of our Patent Office, which, prior to 1865, did not show more motor vehicle patents than could be counted on one's fingers, and a total issue of less than 50,000 patents, which total issue reached 200,000 early in 1878, an increase of 300 per cent in 13 years. The 400,000 issue was reached early in 1889 and the 600,000 early in 1898. Naturally it is impossible to continue the general history with any degree of total inclusiveness because of the vast amount of work being done which had a bearing on the final solution. Much of this work, however bore more directly on the traction engine, the street car and the locomotive, while the efforts toward the road motor vehicle driven by steam comparatively slackened.

Gas Engine Development

The development of the gas engine had by now, 1876, reached such a point as to attract serious attention for stationary power and boat work and pending its development sufficient for motor vehicles, the road vehicle movement somewhat languished. The velocipede had ceased to attract attention and although it continued in use in England to such an extent that races were held there and was shown at the Centennial Exposition in the form of a high-wheel bicycle it did not attract much attention in this country until about 1879. The bicycles exhibited in 1876 were sold and a few others imported, but, being of the high-wheel type, were considered rather as vehicles for athletes than for the common people. Thus the cycle industry did not make much headway until the advent of the safety bicycle and the adoption of the air tire in the later eighties.

The Rostrum

Worn Thrust Bearings Cause Noise

EDITOR THE AUTOMOBILE:—I have an Apperson 1913 4-45 car on which I would like to make an adjustment of the differential. An unpleasant sound issues from the rear wheels when traveling over 20 m.p.h. and I have found that there is a little play in one of the rear wheels. By play, I mean that when rear wheel is jacked, same can be pushed in and out about ⅛ or ¼ in. The trouble I am sure is not beneath the hub cap as I had tightened this nut, and I think that the differential itself must be adjusted. How can I adjust it so as to stop this ringing, grinding noise?

I have noticed this same noise on quite a few passing cars. I also might mention that on taking off the cover plate of the differential I have found that the edges of teeth of the large gear have been chipped. The chipping I am sure had occurred when the car was on rough road, such as heavy sand or mud and think this was caused by the gears not meshing properly. This had happened on quite a few occasions and every time it had happened I was forced to take these chips out as some had lodged between the teeth, causing a jar through the whole car while going. I also notice that my motor is consuming quite a lot of oil of late, which I think is caused by the oil pump working too fast. There is an adjustment screw on the bottom of the motor where the oil supply can be regulated and also a petcock up above showing how fast oil is pumping, but before adjusting I would like to know just how it should show.

Brooklyn, N. Y. P. K.

—The lost motion in the rear axle appears to be due to worn thrust bearings. If the car will be examined by a competent mechanic it is quite sure to be noted that the differential thrust bearings are badly worn and need replacing.

This same reason may possibly be assigned to the noise about which you speak, although this may also be attributed to the condition of the ring gears and pinion. These should be examined at the same time that the thrust bearings are replaced and the differential overhauled.

After a motor is loosened from running the amount of oil required is considerably less than when the motor is new. For ordinary driving the Apperson company recommends that the adjusting screw at the bottom of the pump be closed entirely and then opened three-quarters or seven-eighths of a turn. Of course, if you undertake long trips or run the car under unusual conditions such as through heavy mud and sand more oil will be required and the adjusting screw should be opened accordingly.

Excess Oil Due to Piston Leaks

Editor THE AUTOMOBILE:—Have a model C-25, 1915 Buick touring car which causes me a great deal of trouble by excess oil getting by piston rings into the combustion chamber, fouling plugs and causing carbon deposit.

Have had a new set of rings put in the car but still have the same trouble, although I keep the oil level low in the crankcase.

Would it be advisable to take out the pistons and have an oil groove cut in them, with small holes to let out surplus oil?

If so, would you kindly advise where to place the groove, also the depth of groove and number and size of holes to each groove? Is there any other remedy you could suggest?

2—Would the wiring diagram for an ammeter for the 1914 B-25 Buick be suitable for the C-25, 1915 model? This is shown in THE AUTOMOBILE for Oct. 21.

Pittston, Pa. W. E. S.

—Excess oil in the model C-25 Buick can generally be traced to badly fitting piston rings, scored pistons and scored cylinders. It sometimes happens also that a car user carries too much oil in the reservoir. All these should be examined and the obvious remedy applied.

2—The ammeter for the C-25 can be wired in the same manner as that for B-25 with the exception that on the C-25 it will not be necessary to take the generator apart to cut the strap.

Improper Spark Timing Causes Heating

Editor THE AUTOMOBILE:—Can a honeycomb radiator be cleaned of scale or other matter without taking it apart, and if so, how?

2—What effect would a solution of lye have on the different metals and rubber if it were put in the radiator and the engine run for an hour or so? How would sal soda affect these parts?

3—On my 1914 Velie the spark is set on upper dead center when full advanced. This I know is too late but it should not heat the motor to the degree of boiling while running in fourth speed on level paved roads. The pump is working well and the water seems to be fairly clear. This leads me to believe the trouble is in the radiator as some of the cells in a straight line from top to bottom seem to be much cooler than others. What would you advise me to do with it? The cylinders are free of carbon.

Euclid, Ohio. L. H. V.

—A honeycomb radiator can be cleaned by a solution of common washing soda and water. The proportion is roughly a double handful of soda to a pail of boiling water. The radiator is flushed with this which will remove the scale.

2—Strong alkaline solutions such as you mention would rapidly corrode the parts by setting up an electrolytic action.

3—If the spark is on dead center when fully advanced, it is the cause of all your troubles, because it should be just the other way and be on dead center when fully retarded.

New Facing Remedy for Slipping Clutch

Editor THE AUTOMOBILE:—I have a 25-hp. Maxwell runabout built this year which I bought in June. The clutch is faced with some fabric and for the past month I have been bothered by the clutch slipping. Have had the garage men put Fuller's earth on the face but of no avail; evidently the face is so smooth that the earth will not stick.

Will you kindly suggest a remedy, as the results are very annoying? The car will stand in the middle of the street on high gear and not affect the running of the engine, that is, the clutch in high will not retard the engine to any appreciative degree, although it will hold on low and second but better in the former.

Bradford, Pa. E. C. C.

—There must be something radically wrong with the particular facing on that car and would suggest your having a new clutch facing applied. If this does not remedy the trouble there must be some interference with the clutch entering the flywheel as far as it should. Perhaps the clutch pedal is striking the floorboard preventing it from engaging. As this trouble has not been noticed in any large number of Maxwell cars it is no doubt due to some local derangement.

Fuller's earth has little or no effect on the clutch lining used in these cars. It is very possible that heavy grease has leaked into the clutch housing and that the lining is more in need of thorough cleaning than anything else. If you will follow the directions given in your instruction book and lubricate with a very light oil, one of the possible causes of trouble will be removed.

Layout of 40 by 90 Ft. Garage

Editor THE AUTOMOBILE:—I am going to build a brick garage 40 by 90 ft., and would like to have you show me the ideal layout for its equipment. I want to use a vulcanizing plant, a lathe, a motor generator, charging set for batteries and such other equipment as necessary for an up-to-date repair shop.

Please list the necessary equipment and where I can secure it. What type of lathe would be best to buy and kindly give me a floor plan of an up-to-date garage of this size.

Montgomery, W. Va. W. C. A.

—The layout which would probably fit your desires better than anything else is shown in Fig. 1. As regards the necessary equipment, that which you have mentioned and a sensitive drill, together with a set of bench tools, will be about all that you will need to start. It will not be necessary to buy this equipment new, as it is better to pick it up wherever opportunity is found.

No Accidents in Elgin Race

Editor THE AUTOMOBILE:—What is the piston displacement of an eight-cylinder motor 3⅞ by 6?

2—What makes of cars and what drivers captured the first five places at the Elgin trophy race? Give time in miles per hour and the prizes.

3—Were any of the drivers killed or injured?

4—What is the difference between a storage battery and a dry battery?

5—Could electricity be used to heat the steam generator on the Stanley car instead of gasoline? If not, why?

6—Is the Stewart starter on the Ford noiseless in operation? Could it be made to operate in either direction?

7—Has the Mercer company retired from racing? If not, why didn't it race this year?

8—Do the valves of the Knight engine require grinding? Or do they need the attention that the valves of a poppet engine require?

9—Is there an electric motor built which can be run in either direction? How is an electric car reversed?

10—Could electricity be used to heat water in any way? If so, how? Give full details.

11—Could compressed air be used in a steam or water turbine in place of steam or water? Would 100 lb. continuous pressure operate a 20-hp. turbine satisfactorily?

12—Where is the Ahems Fox car made? By whom?

Cooper, N. C. S. T.

—The displacement is 566 cu. in.

2—At the Elgin trophy race this year only four cars finished. These were Anderson's Stutz, Cooper's Stutz, O'Donnell's Duesenberg and DePalma's Mercedes in the order named. The speeds in m.p.h. were 77.256, 76.258, 75.769 and 75.690. The prizes for the Elgin trophy were $2,000 for first place, $650 for second place, and $350 for third. In addition to this the drivers all received $100 for each 100 miles completed.

3—There were no accidents.

4—A storage battery is one in which the chemical condition which creates an electromotive force can be restored by causing a current to flow into the battery. A dry battery is one in which the current is produced by chemicals contained within a waterproof case and which is of such a nature that once it is exhausted the battery cannot be again used.

5—There would have to be present some great source of electric current which would be capable of producing enough heat to provide the high temperature required. This, of course, would be impossible.

6—There is no mechanical mechanism of this nature which is absolutely noiseless and it is a matter only of degree of noise. It is quiet in operation. The Stewart starter is designed to operate in one direction but probably could be altered if necessary.

7—The Mercer Co. has not announced that it has retired definitely from racing, although the company did not concentrate any great attention on the matter this year.

8—No.

9—Electric motors can be run in either direction by reversing the flow of the current.

10—Yes. The flow of electric current through any resisting medium provides heat.

11—This would depend on the details of design.

12—THE AUTOMOBILE has no record of this car.

Gear Ratios of 1909 Packard

Editor THE AUTOMOBILE:—I have a Packard 30 runabout, 1909 model, and would like to know the actual horsepower.

2—What are the gear ratios? How many revolutions per minute does the motor turn at full speed? What is the bore and stroke? What speed can the car attain if in good condition? I have never driven it to the limit, but have passed cars which claim 60 m.p.h. and over.

3—Will a 36 by 4½ Kelly-Springfield Kant Slip tire give proper service on the rear wheels? I now have 37 by 5, but would like to put on the smaller size.

4—How many miles per gallon of gasoline and oil should I obtain on good roads at an average speed of 18 m.p.h.?

Mattapan, Mass. H. F. M.

—The motor in the 1909 Packard 30 runabout will develop about 50 hp.

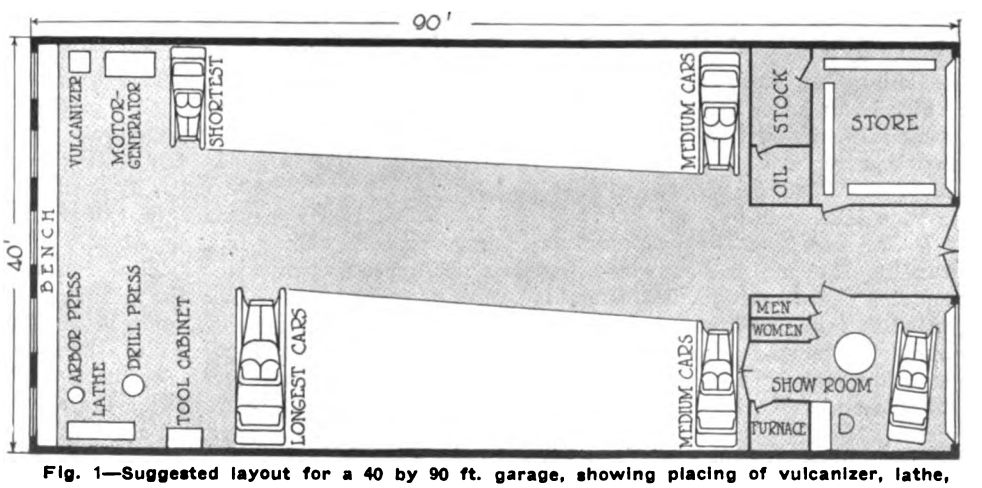

Fig. 1—Suggested layout for a 40 by 90 ft. garage, showing placing of vulcanizer, lathe, generator, charging set for batteries, etc.

2—This model was supplied with two gear ratios, one of which was 3.21 to 1 in which the pinion and ring gear had fourteen and forty-five teeth, respectively, and one of 2.64 to 1 in which the number of teeth were seventeen and forty-five, respectively. The motor develops its maximum horsepower at about 1200 r.p.m. While the speed at which the car will travel depends upon the gear ratio employed, when in this condition it should be able to travel 60 m.p.h.

3—The 36 by 4½ tire size should be adequate for this model when equipped with a runabout body unless unusual loads are carried.

4—The gasoline and oil mileage on a car of this age are difficult to estimate. It should be possible, however, to obtain better than 12 miles to the gallon of gasoline and 150 miles to each gallon of cylinder oil.

Relay Points Not Easily Adjusted

Editor THE AUTOMOBILE:—I have a 1915 model 31 Empire, with a Remy electric system. I just installed a new relay and the fuse burns out almost as quickly as I put them in. The points are not pitted. The generator is all right and there are no grounds or shorts anywhere. I think the trouble is improper adjustment of the relay points. Can you please tell me how to adjust a Remy relay?

Canonsburg, Pa. F. G. S.

—While it is possible to adjust the Remy relay satisfactorily, such adjustment should not be made by anyone who is inexperienced in this work, and if the relay has not been tampered with and thrown completely out of adjustment if you will see that the large regulator points have a maximum opening of approximately 0.02 in.; that they are clean and not pitted and also that all connections are properly made securely with the wiring in good condition, the troubles should be obviated.

Ratio in New Sheldon Axle

Editor THE AUTOMOBILE:—What is the ratio of the worm to the master gear in the Sheldon axle for 1500 lb. capacity cars as described in a recent issue of THE AUTOMOBILE?

2—What was the ratio of the gears in the axle on the car driven by Resta at Chicago?

3—Are aluminum cylinder castings usually lined with cast iron?

4—Was it for lack of speed that the Porter sleeve valve cars were unable to qualify at Indianapolis?

Kansas City, Mo. W. E. B.

—The standard ratio in this axle is 6.5 to 1.

2—The ratio of these gears was approximately 3 to 1.

3—Many recommend the practice of lining aluminum cylinder castings with a cast-iron sleeve.

4—No.

Truck Knocks at Low Speed

Editor THE AUTOMOBILE:—I have an Alco 3½-ton truck which has a knock in the motor. It appears only when running idle and at slow speed. It also disappears when the spark is retarded. Could this be a loose wristpin or a piston slap?

Blue Island, Ill. W. H. S.

—The fact that the knock or pound appears only when running idle and at slow speed, but does not appear when running slow in gear, indicates nothing, as of course, at slow speed in gear, the motor has a wider throttle opening than at the same speed idle; also the inertia of the truck acts as an additional flywheel, so that it may be assumed that the trouble appears only when the minimum throttle opening is used.

That the retardation of the ignition results in the disappearance of the knock indicates that it is in all likelihood a spark knock. An engine in proper shape should not knock when idle, but nevertheless in heavy engines it often happens that with the throttle nearly closed and the spark fully advanced the motor will knock. The sound is a sharp click, somewhat like the sound of one bottle being hit against another.

A piston slap, a loose wristpin or any other mechanical cause would be unaffected by changing the spark adjustment.

Motor R.P.M. at 50 M.P.H.

Editor THE AUTOMOBILE:—On a car with 34-in. road wheels and the engine geared 4 to 1, how many revolutions per minute does the engine make at a speed of 50 m.p.h.?

2—In descending a long grade is it harmful to hold the car in with the brake, while the machine is in gear, the clutch in and the engine idling?

Reedsville, Pa. F. E. K.

—On a car with 34-in. wheels and 4 to 1 ratio at 50 m.p.h. the road wheels make 494.4 r.p.m. and the motor with a gear ratio of 4 to 1 makes four times this amount or 1977.6 r.p.m.

2—As long as the car is tending to push the motor, it does no harm to keep the clutch in while the brake is applied.

Correct Timing for 1912 Regal

Editor THE AUTOMOBILE:—Will you kindly give me the timing of a 1912 Regal 30-hp. touring car? I have had the motor down and think that the valve and magneto timing is wrong because it backfires. I have tried different carbureter adjustments but with no success.

Roselle, N. J. C. P.

—The magneto in the 30-hp. car should be set so that the spark will occur at the instant the piston reaches the uppermost point of the compression stroke. In other words, on upper dead center with the lever in full retard position. The timing of the magneto can be altered by changing the position of the small timing gear on the end of the magneto shaft, but to make this adjustment it is necessary to remove the radiator and the timing gear housing.

If the magneto is timed a little too early this can usually be corrected by merely changing the position of the timing gear on the end of the magneto shaft one tooth to the left facing the engine from the front. If the magneto is timed late, or, in other words, if the spark occurs after the piston has traveled down a part of the distance, the timing gear at the end of the magneto shaft should be set one tooth to the right, or perhaps two if necessary. Changing the gear one tooth means approximately 1 in. on the face of the flywheel.

The timing of the valve is indicated on the flywheel by the figures 16, 34, 40, 10, ¼ and 2/3. These lines and figures represent distances and measurements in degrees from the two lines diametrically opposite to one another, one marked 1-4 and the other 2-3. These two marks coincide respectively with the upper dead centers of 1 and 4 pistons and 2 and 3 pistons.

To determine whether or not the valves are timed properly, first open the relief cock on top of the cylinders, then turn the flywheel to the left until the line marked 1-4 is opposite, or rather directly under the center line of the cylinders. At this point the exhaust valve in either No. 1 or No. 4 cylinder should just commence to close. If you find that the exhaust valve in No. 4 cylinder is beginning to close, and you wish to check up the valve timing of No. 1 cylinder, turn the flywheel around to the left, one complete revolution, until the line 1-4 is again brought under the center line of the cylinders; then continue slowly turning the flywheel about an inch or so to the left until the line marked 10 coincides with the center line of the cylinders. This is the point at which the exhaust valve in the No. 1 cylinder

should just seat itself or close. To determine whether or not the valve is seated, see if the tappet or push rod underneath the valve can be turned with the fingers. If the tappet turns freely the valve is seated, and if the tappet is hard to turn, that will show that the valve is still being held slightly open. If this is the case, loosen the lock nut on the tappet screw and turn the screw down until the valve just seats; then turn the lock nut down tight against the tappet.

To check up the timing of the inlet valve in the same cylinder, turn the flywheel ¾ in. or so toward the left, until the line marked 16 comes under the center line of the cylinders. At this point the inlet valve in the No. 1 cylinder should just begin to open. Turn the flywheel a little better than one-half a turn to the left, stopping when the line marked 34, three lines to the right of the 2-3 center line comes in line with the center of the cylinders. At this point the inlet valve in the No. 1 cylinder should just close.

To see if the exhaust valve in the No. 1 cylinder opens at the proper time, revolve the flywheel three-fourths of a turn to the left, and stop when the line 40, the first line to the left of the 2-3 center line comes in line with the center of the cylinders. This is the point where the exhaust valve in No. 1 cylinder should just begin to open. The above completes the timing of cylinder No. 1.

To time cylinder No. 2, turn the flywheel until the line marked 2-3 is in line with the center line of the cylinders. If the exhaust valve in the No. 2 cylinder is closed, turn the flywheel through one complete revolution, until the line 2-3 is up again; the exhaust valve in No. 2 cylinder should then just be starting to close. Proceed now as in timing the No. 1 cylinder.

The No. 4 cylinder is timed from the center line 1-4 and the No. 3 cylinder from the center line 2-3. When the valves are closed there should be clearance between the valve stems and the tappet screws of from 0.003 to 0.004 in. This amount of clearance is necessary to allow the valves to seat tightly.

Racing Record of Meneghetti

Editor THE AUTOMOBILE:—Kindly give me the racing record of Meneghetti, an Italian, who drove a 120-hp. Fiat. He was killed, I believe, at Savannah when his machine turned turtle.

Charlottesville, Va. C. E. S.

—Louis Meneghetti came to this country some time during 1910 or 1911 and for about two seasons campaigned with the Moross racing team.

In September, 1912, he severed his connection with this team and joined another team then known as the Powell racing organization and competed in several dirt track meetings during that season. In 1913 he competed in some small dirt track events independently and at Norfolk, Neb., on Nov. 17, 1913, his Fiat turned over as he was rounding the turn and Meneghetti was killed.

How Oil Is Consumed

Editor THE AUTOMOBILE:—What is considered a reasonable consumption, by a four-cylinder motor 3⅞ by 4½, of light, medium and heavy oils? Kindly explain how the oil is consumed; also the different ways it can be wasted or lost?

2—What is the function of the small holes through the cylinder walls?

San Francisco, Cal. J. G. H.

—Three hundred miles per gallon would be reasonable; 600 would be good.

Oil is consumed merely through burning in the combustion space. Every time the piston goes down, it leaves the cylinder walls wet with oil and this oil is burned off. This action occurs even when no smoke is emitted. Oil usually wears out by continual passage through bearings, and becomes dirty. It can be restored by boiling, screening, etc., but the trouble is more than the oil is worth.

2—There are no automobile motors with holes through the cylinder walls. Probably you mean the piston. Small holes through the piston are a factor in preventing too great an accumulation of oil on the cylinder walls, as well as in reducing the weight of the piston without impairing the strength.

Ford Magneto Develops 7.5 Amp.

Editor THE AUTOMOBILE:—Can you tell me what amperage is developed by the magneto of the Ford 1915, model T, at different speeds, taking as a minimum 15 m.p.h., also at 20 m.p.h., and at 30 m.p.h.?

Kindly name the defects of this system of lighting, and tell me how I can secure more even lighting at the different speeds.

Hamburg, Pa. C. E. K.

—The Ford magneto at 15 m.p.h. develops its maximum amperage which is quite close to 7½ amp.

As the current generated by the magneto varies according to the speed of the motor, it naturally follows that at very low engine speeds the lights will not be as bright as when the motor is turning over faster. However, for all ordinary purposes, sufficient light is given by the headlamps. The present 9-volt bulbs were determined upon because they provided the best light at the widest range of engine speed. If an owner desires to drive slowly with the lights on at night, he can secure brighter lights by using 7- or 8-volt bulbs, but the probabilities are that the life of the lamp will not be as long.

2000 Maximum R.P.M. of 1910 Thomas

Editor THE AUTOMOBILE:—I have a Thomas six-cylinder 1910 model K and would like to know the following:

1—What speed could this car make originally with standard equipment?

2—What is the maximum number of revolutions of this motor?

3—Where can I get repair parts?

Sea Bright, N. J. F. E. G.

—This car can make about 60 m.p.h. when in good condition.

2—The revolutions per minute of the motor at maximum horsepower are about 2000.

3—Repair parts for the Thomas car can be secured from the following: E. R. Thomas Motor Car Co., Buffalo, N. Y.; J. Rosenfield, 521 Sixth St., So. Boston, Mass., and the Automobile Construction Co., 2637 Cottage Grove Ave., Chicago, Ill.

Crankshaft Speed a Variable Quantity

Editor THE AUTOMOBILE:—Do the cylinder type of shock absorbers cause a car to skid when driving over bumpy roads?

2—Do automobile trade directories give addresses of all shock absorber manufacturers?

3—What is the gear ratio of the Overland on reverse and on low?

4—At what crankshaft speed does it deliver its maximum horsepower?

5—What speed should the model 80 Overland make when in good working order?

Bouton, Iowa. C. M.

—They should not do so and as far as is known, do not.

2—They endeavor to do so.

3—14.5 to 1.

4—The exact crankshaft speed will vary in different motors, but it is approximately 1800 r.p.m. for maximum horsepower.

5—44 to 50 m.p.h.

Use of Optical Indicators for Checking Defects in Functioning of Motors

DURING this period when many motors for automobiles, motor trucks and motor boats are being re-designed or replaced by new ones, with a view to incorporating as much of recent progress in efficiency and economy as the manufacturer considers it safe to strive for in practice, or for any other similar purpose, the use of indicator diagrams, for comparing results from the old and from the new designs and for examining motors submitted for examination, is spreading to factories where they have been used very sparingly or not at all before, and ability to do the work of taking and interpreting the diagrams is coming to be one of the requirements not only of engineers but of foremen and other mechanics as well. Amateurs and dealers may soon take up this method, also, as one of the readiest means for examining the condition of a motor that has seen service.

The data of the most recent American development in this respect are not yet at hand, but meanwhile an account of the subject from the German viewpoint—as presented in a number of recent issues of *Auto-Technik*, will be found of practical interest to a large number of persons.

As American, British and French indicators are generally known in the automobile industry, illustration and description of them may here be omitted, and the optical indicator of Otto Schulze's design which is widely used in Germany may be taken as an example to illustrate the general mode of operation with instruments of this order. It differs from the other designs mainly by the peculiar arrangement and bearings of the carrier for the mirror. Fig. 1 shows the arrangement in elevation and plan, diagrammatically. The water-cooled diaphragm 1 is as usual connected with the motor cylinder by a tube and carries the spindle 2 for transmitting the movement from the diaphragm through the springy lever 3 to the mirror holder. This holder is secured by the thin leaf spring *F* to the slide 5 which can turn around the pin 4 projecting from the bedplate. In the slide there is shown a circular hole making room for a turnable eccentric disk 7, but in practice a crank mechanism takes the place of this device. The manner of operating is as follows:

When the rising or decreasing pressure in the motor cylinder raises or releases the diaphragm, the movement taken through pin 2, lever 3 and holder 6 changes the angularity of the mirror toward the light source *L* and the bedplate. This change in angularity is recorded on the ground glass screen as a change of pressure. The horizontal change of the mirror's position with relation to the light source is effected by the turning of slide 5 around pin 4, the eccentric 7 being connected by a gear with the camshaft of the motor. To obtain a correct diagram, the phases of the movements must correspond; that is, the turning-ratio of the mirror must be brought into a certain relation to that of the motor shaft, and for this purpose there is provided an adjustment for the crank of the indicator between limits of 1 to 4 and 1 to 6, which is usually sufficient. Fig. 2 shows a Schulze indicator for a four-cylinder motor, arranged for producing four similar diagrams for the four cylinders and having them visible in a row for easy comparison.

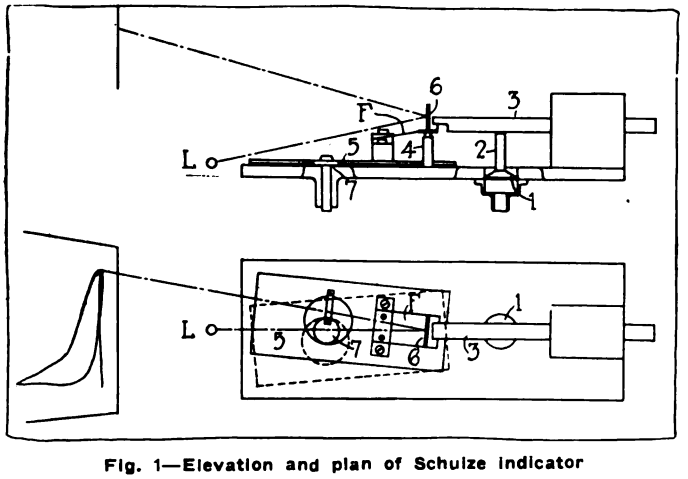

Fig. 1—Elevation and plan of Schulze indicator

A, *B*, *C* and *D* are the ground glass screens on which the diagrams are projected under the influence of the shrouded electric bulbs *E*, *F*, *G* and *H*. The apparatus is secured to the motor by means of bracket *L* and is actuated from the motor by shaft *K* which can be correctly adjusted at *M*. Fig. 3 shows the manner of mounting this indicator on a four-cylinder motor. *M* is here the indicator and 1 is the gear transmission from the motor. The four gas tubes taking pressure from the motor cylinders to the diaphragms are provided with stopcocks 2. Vibrations of the motor have with this mounting no influence on the accuracy of the indicator's work.

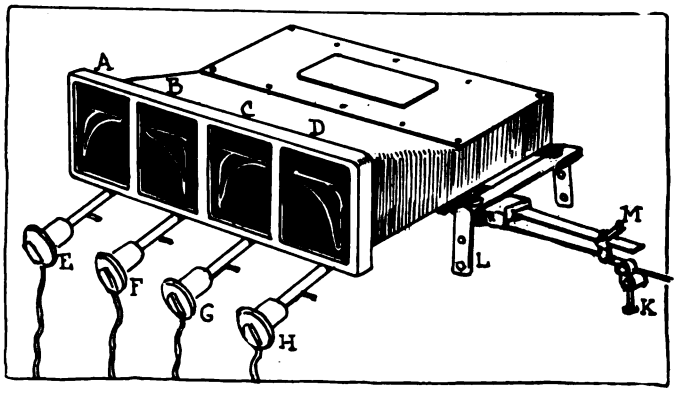

Fig. 2—Arrangement of screens and lights

These indicators are usually furnished with two sets of diaphragms, one for high pressures to indicate normal operation under power and one for low pressure, with which the functioning of the valves can be studied with the ignition and gas admission cut out. The high-pressure diaphragm for the Schulze indicators produces a scale in the diagrams of 3 millimeters per atmospheric pressure, while the more flexible membrane for diagrams of the compression gives a scale of 10 millimeters per atmosphere.

When a multiple indicator is used, the diagrams simultaneosuly traced for the different cylinders should be alike, and any difference in them points in itself to some error. If the diaphragms are not exactly of equal tension, the differences which will appear in the diagrams easily lead to wrong conclusions. It is therefore recommendable to test them by comparing with diagrams obtained by using the same diaphragm successively for the four cylinders.

The ground-glass screen of an indicator is usually so arranged that it can be conveniently replaced by a photographic plate. In some instances photographic films have also been used instead of plates. The curve of the diagram appears as a continuous luminous line on the dark background of the screen, the effect being that indicated in Fig. 4. A Schulze

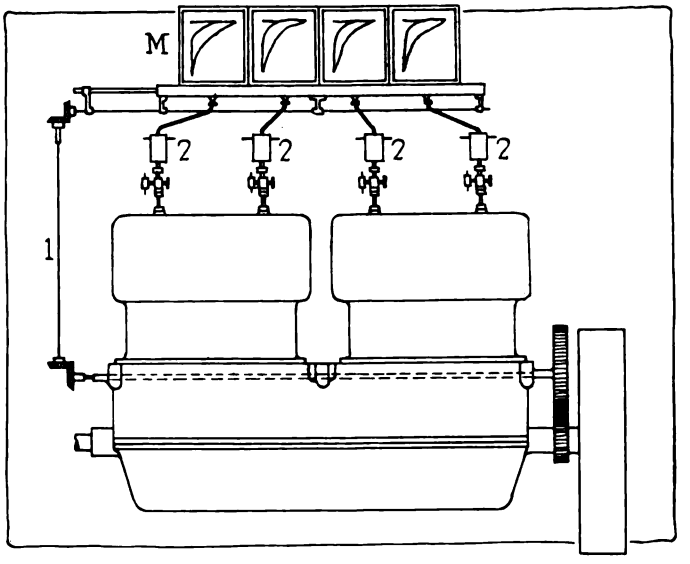

Fig. 3—Mounting of indicator for 4-cylinder motor

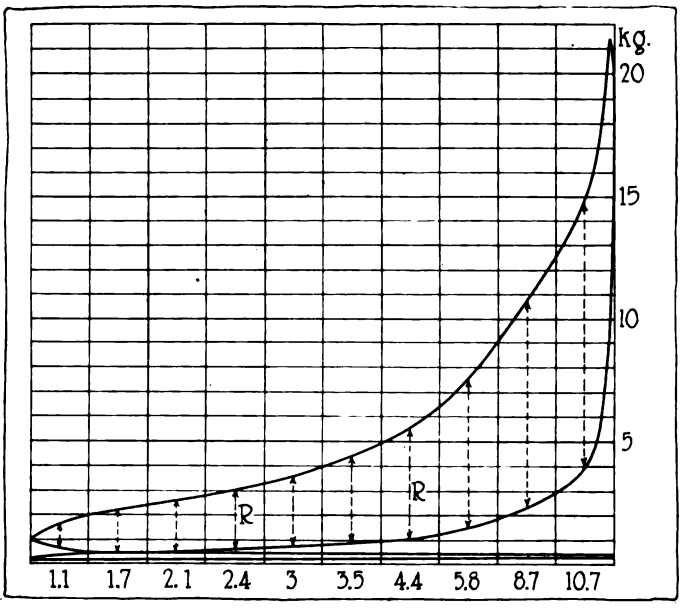

Fig. 5—Method for finding mean effective pressure

diagram, for example, is 70 millimeters long, but, if it is desired to follow the work of the motor more closely than is possible on this scale, a projector lens is employed to throw the diagram on a more distant and larger screen, where its length may be perhaps 500 millimeters. It is especially interesting to observe the lightning changes in the diagrams occurring at the different stages of the motor work so clearly as they appear with this large magnification. With the use of improved light sources the observations can be conveniently made even by broad daylight.

When the diagram is to be permanent a photographic camera is inserted instead of the glass screen, and the plate is taken out and developed in the usual manner. If bromide or other negative paper is used in the camera instead of the plate, the diagram is obtained in black on white by the developing. When no photographic apparatus is used, however, and the motor is operated by its own power the whole curve of the diagram is always visible to the observer, as the retina of the observer's eye easily retains the whole image during the very short period in which it is produced, and all defects in the working cycle of the motor can therefore be at once recognized, whether due to insufficient filling of the cylinders with gas, poor compression, leaks, incorrect functioning of the valves or wrong timing of the ignition, and the proper remedy can thus be devised without long groping or guessing.

[An exception is noted for the case that the motor is cranked slowly by hand to test compression, under which condition the generation of the curve can be followed from point to point but is not seen at any moment in its entirety, on account of the slowness of the movement, and for a test of this kind the photographic method is preferable, even if it is not otherwise necessary to preserve a record of the test.]

Aside from its utility for demonstrating errors in the functioning of a motor, the indicator can be employed to determine its mechanical efficiency. It gives the means for calculating the indicated horsepower, and by deducting from this the power shown by brake test the difference stands for the mechanical losses due to friction. To obtain the indicated power, the diagram is divided by vertical lines in ten equal parts (Fig. 5) and the ordinates R of the diagram are measured in the middle of each part, in millimeters. These figures are converted into pressures in kilograms per square centimeter according to a schedule which accompanies each indicator from its maker. Usually 2 or 3 millimeters represent 1 kilogram per square centimeter. These values are entered and added up at the foot of the diagram, and the sum divided by 10 represents the mean effective pressure. In Fig. 5 this mean is found to be 4.27 kilograms. If the cylinder has, for example, a bore of 120 millimeters and a stroke of 145 millimeters and the motor speed is 950 r.p.m., the indicated horsepower is found from the formula:

$$N_i = \frac{O \times P_i \times n \times l}{60 \times 75}$$

in which O is the piston area (here 113 square centimeters), P_i the mean effective pressure, n the number of explosions per minute (here 950 divided by 2, or 425) and l the stroke in meters (here .145 meter). By inserting these values one has:

$$N_i = \frac{113 \times 4.27 \times 425 \times 0.145}{60 \times 75} = 6.61 \text{ indicated horsepowers.}$$

Frequently, parts of the exhaust, the compression and the suction curves form a loop and in that case include a certain area, but this is usually (as in Fig. 5) so small that it can be neglected. It represents, however, negative work, and, if it is large enough to be considered, it can be figured out from its ordinates in the same manner as the main area, and the mean negative pressure can be deducted from the working pressure to find the value to be used in the formula for indicated horsepower.

After the indicator has been mounted upon the motor the cycle of the indicator movements must first be adjusted to correspond to that of the motor. To this end the motor is turned by hand. During the compression stroke the pressure in the cylinder then rises to nearly that of normal compression, and during the following stroke the pressure

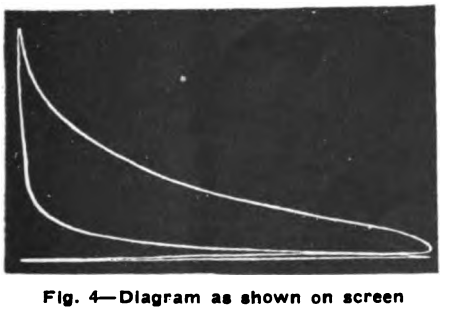

Fig. 4—Diagram as shown on screen

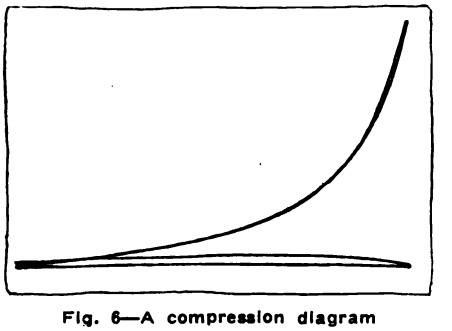

Fig. 6—A compression diagram

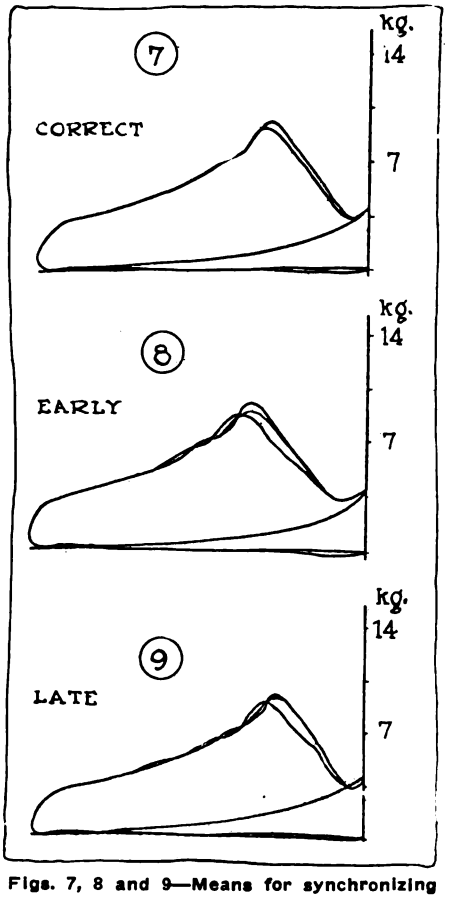
is shown to diminish according to the same curve, provided the cycles correspond properly. The total curve is then like that shown in Fig. 6, the compression and expansion curves almost coinciding. The first portion of the expansion curve falls a little below the compression curve, because at that moment heat generated by the compression is taken up in the cylinder walls. If a more marked lack of coincidence in the two lines is shown, the adjustment of the indicator is operated until correspondence is produced.



Figs. 7, 8 and 9—Means for synchronizing indicator and motor

The working diagram can also be used for adjusting the cycle. While the motor is at rest such an adjustment is first made of the indicator's gear or lights that the luminous point is at the end of its course when the piston has reached the end of its stroke. The motor is then started with the spark so late that the charge is not ignited till the dead center is passed. The adjustment for securing synchronic movements is now manipulated until that portion of the diagram which represents the end of the compression stroke and the beginning of the working stroke assumes the shape it has in Fig. 7. If the cycle of the indicator is ahead of that of the motor a diagram like Fig. 8 is obtained, while one like Fig. 9 shows that the indicator cycle is behind. The correct adjustment is of great importance. With a certain motor it was shown, for example, that a fault of 6 deg. in the indicator adjustment gave a mean effective pressure of 7.03 kilograms per square centimeter, while a correct adjustment gave 6.25 kilograms.

When the motor works to best advantage, its indicator diagram should correspond approximately to the ideal diagram which may be construed from the data of the motor. This theoretical diagram is constantly kept in mind when one interprets the meaning of variations in shape of actual diagrams, and it is therefore the basis for making practical use of indicators. It is shown in Fig. 10.

The Ideal Diagram

On the zero line the piston stroke *ac* of the motor is marked as abscissa, and on the vertical axis are measured, as ordinates, the pressures existing in the combustion chamber. The distance from O to *a* represents the compression chamber or dead space in the cylinder. When the piston moves from *a* to *c* in the suction stroke, the pressure above the piston remains in theory atmospheric (under the assumption that the charge follows the piston readily) and the pressure curve becomes the straight line AC which is parallel with the zero or vacuum line. During the compression stroke the piston moves back from *c* to *a*, and the pressure increases at the rate of the adiabatic curve CE (adiabatic = calculated on basis of pressures and volumes only) on the supposition that no heat is transmitted from the cylinder wall to the gas. At point E the compressed charge is now ignited and the pressure rises instantaneously from E to F. At F begins the expansion or work stroke and the piston moves again from *a* to *c*. Again assuming no heat transmission to take place, the expansion curve becomes adiabatic and runs from F to H. The exhaust valve is opened at the end of the work stroke, and the pressure drops suddenly from H to C. By the subsequent exhaust stroke of the piston from *c* to *a* the pressure remains atmospheric and is represented in the straight line CA.

Meaning of Areas

The diagram area ECHF represents the work done by the cylinder. Consequently every motor builder aims to obtain the largest possible diagram area, and Fig. 10 represents the theoretical maximum, which cannot be reached in practice, as the actual conditions in a four-cycle motor deviate considerably from the assumptions under which the ideal diagram is constructed. First, the suction stroke produces more or less depression in the cylinder, so that its curve 1, in Fig. 11, falls below the straight line indicating 1 atmospheric pressure. During the compression the cylinder walls part with a certain amount of heat to the gas mixture, the tension of which is thereby increased, and the compression curve 2 lies for this reason higher than the theoretical curve CE in the later portion of its course. On the other hand, the inflammation of the gas is not instantaneous but requires a little time, and it is therefore necessary to start the ignition before the upper center is reached, for example at *m*, Fig. 11. The straight line EF in Fig. 10 is thus replaced by the curve *m*2 in Fig. 11. During the explosion stroke the gases impart heat to the cylinder wall and their pressure is reduced accordingly, so that the real expansion curve 3 drops considerably below the theoretical

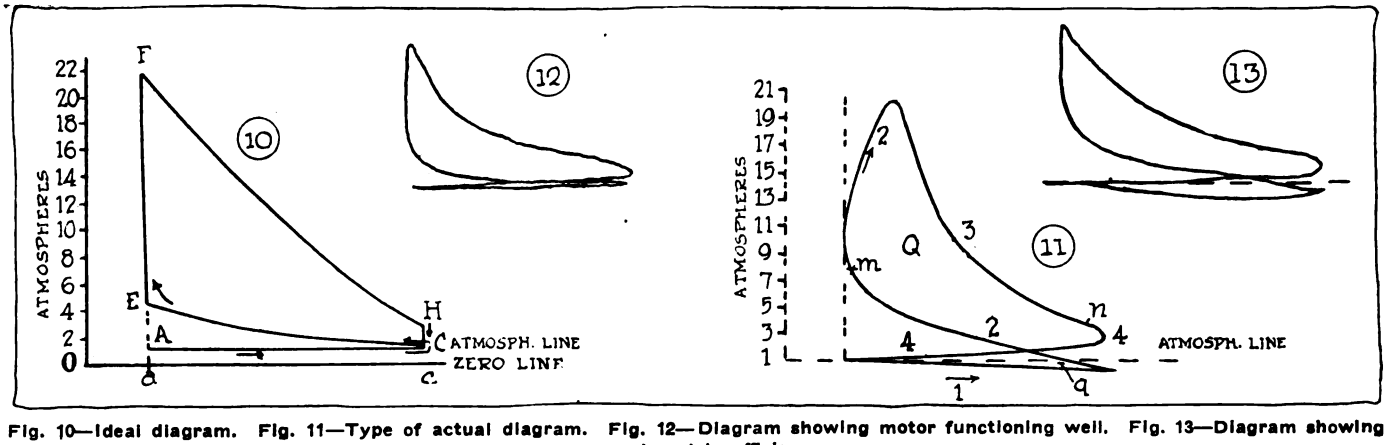


Fig. 10—Ideal diagram. Fig. 11—Type of actual diagram. Fig. 12—Diagram showing motor functioning well. Fig. 13—Diagram showing poor volumetric efficiency

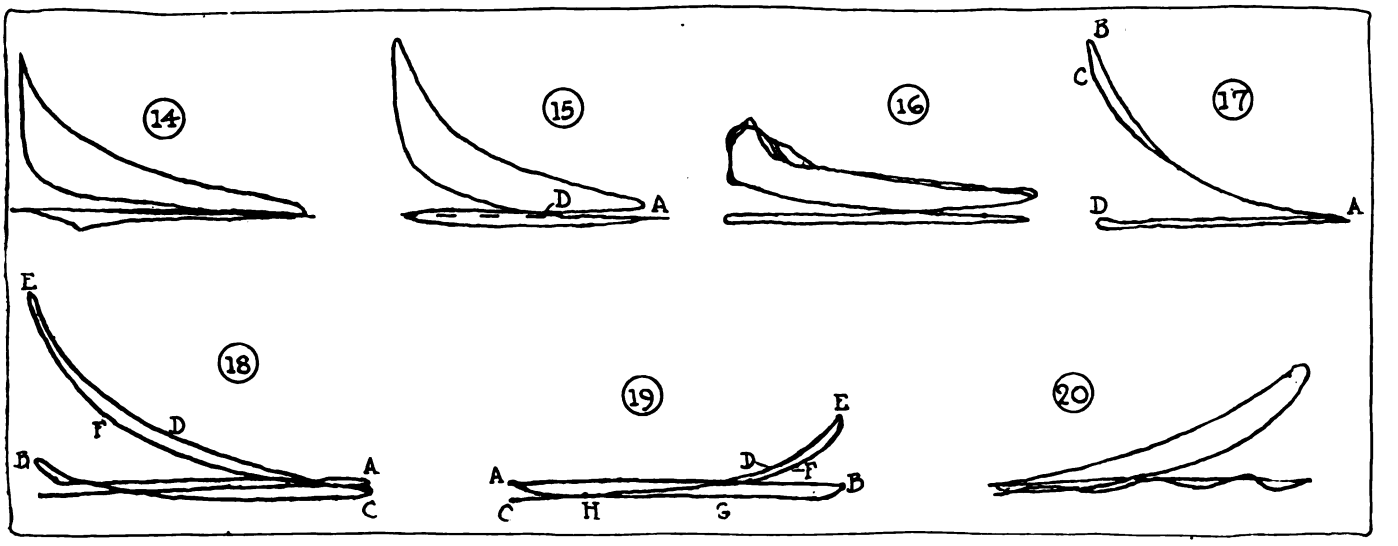


Figs. 14 to 20—Diagrams indicating defects in the intake or in the compression, as explained in text

curve FH. The exhaust valve is also opened before the piston reaches lower center, as at *n*, to avoid back-pressure, and the curve from *n* downward to the right indicates the diminishing pressure. Finally, the pressure of the exhaust gas will be higher than atmospheric during all or nearly all of the exhaust stroke, and the exhaust curve 4 therefore lies higher than the horizontal line of atmospheric pressure.

All these disadvantages are shown with exaggeration in Fig. 11, which however makes it plain that the diagram area Q, from which the lower diagram area *q*, being negative, must be deducted, is considerably smaller than the theoretical diagram area of Fig. 10.

A very good actual diagram is reproduced in Fig. 12. The compression is faultless, ignition and carburetion are good, the valves work properly and back-pressure against the exhaust is reduced to a minimum.

Every disturbance in the functioning of the motor acts at once on the shape of the diagram, and usually a certain deviation from the normal in the curves of a diagram may be correctly ascribed to a certain corresponding defect in the functioning of the motor as its cause.

In the following, causes and effects of this order are explained and illustrated.

Diagrams of Faulty Induction

When the suction curve for its entire length runs considerably below the atmospheric level without showing a definite curvature or break, as in Fig. 13, the intake valve may be of too small diameter or its lift may be insufficient, but it is also possible that the intake channel is too narrow or has been clogged, so as to throttle the whole gas mixture strongly.

If the beginning of the suction stroke shows a rather sharp downward point, as in Fig. 14, the intake valve opens either too late or too slowly, causing a considerable depression in the cylinder before the gas finds the passage open. But when the intake valve closes too slowly or too late, the beginning of the compression curve will coincide with the line of atmospheric pressure, as AD in Fig. 15, and the compression will not really begin till the piston has reached D. It happens frequently at trials of new motors that all of these sharply marked irregularities occur in the same diagram. With the gases so strongly throttled that the cylinder does not receive a full charge, the diagram can take the shape of Fig. 16, where the great reduction of the explosion pressure is conspicuously shown.

To examine the tightness of piston rings and valves it is better to take a compression diagram than a working diagram. It can be obtained either by cutting out the spark and letting the motor run a few turns thereafter or by turning the motor by hand a few turns while it is still warm.

Diagrams of Faulty Compression

Fig. 17 shows a compression diagram of a motor with poor compression. The motor in this case had unmuffled exhaust and was still warm. If all organs had been air-tight, the compression curve AB should have coincided with the expansion curve CA. But as in reality gas escaped at rings or valves or both, the expansion curve CA came notably lower than AB. It is also seen in this diagram that the exhaust curve at D is arched slightly upward, and this was due to too early closing of the exhaust valve, causing some compression at the end of the exhaust stroke. The intake valve, it is also shown here, opens too late, which should be corrected in the valve control.

Fig. 18 shows a very bad compression diagram. The exhaust curve AB has strong back-pressure, and the exhaust valve closes too early, as indicated by the raise at B. The suction curve BC runs far below the atmospheric line, pointing to an undersized intake valve. Finally, the compression is also shown very poor, since the expansion curve EFA falls below the expansion curve CDE.

If the gas mixture is strongly throttled, the compression diagram takes the shape of Fig. 19. BGC is the suction curve, which plainly shows the throttling. CDE is the compression curve and EFH the expansion curve. As the exhaust valve opens as early as at H, the interior pressure in the cylinder is reduced to atmospheric from H to A, and this is maintained during the exhaust stroke AB.

A motor with automatic intake valves gives a diagram in which the suction curve shows a wavy course, as in the compression diagram, Fig. 20. The waves, compared with the steady course of the suction curve for a mechanical inlet valve, indicate plainly the superiority of the latter. Fig. 20 also shows a very inferior compression, the compression and expansion curves being separated.

Diagrams of Faulty Ignition

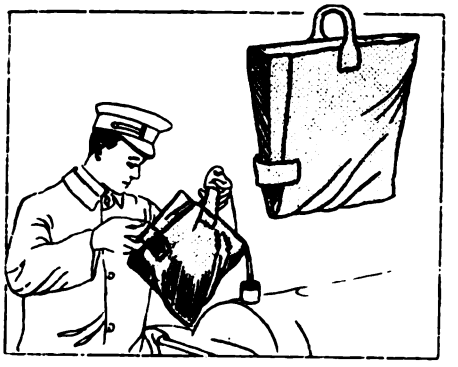
Errors in the timing of the ignition are marked very plainly in indicator diagrams. Fig. 21, *a* to *f*, shows diagrams obtained by different timing. The effect of premature ignition taking place when the piston has finished only three-fourths of the compression stroke is shown in diagram *a*, and *b* shows the effect when there is 20 per cent left of the compression stroke. Both diagrams have the loop which is characteristic of an over-advanced spark.

(To be continued)

ACCESSORIES

Rayntite Folding Water Bucket

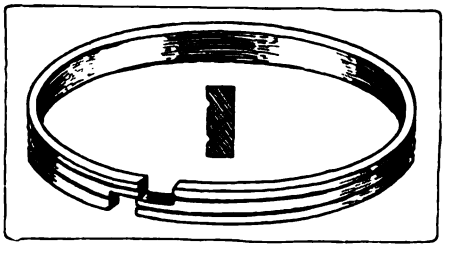
REALIZING the possibilities for a folding water bucket, the Fabrikoid company has brought out a design of waterproof Rayntite which is very compact. Rayntite is the material used by the company in its automobile tops and in the bucket all seams are stitched and cemented with a special adhesive to prevent leaking. It holds 1½ gal. of water and pours easily into the radiator cap. Rayntite does not harden or crack so that the bucket may be folded and put under the rear seat cushion. Price, 75 cents.—Du Pont Fabrikoid Co., Wilmington, Del.



Rayntite folding water bucket and its use

Rittenhouse Piston Ring

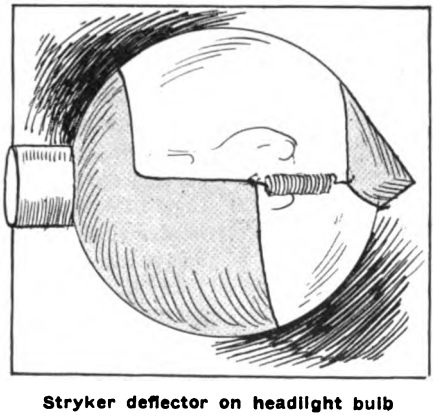
A piston ring designed to eliminate gas leakage has been developed by George R. Rittenhouse and has the feature of having oil rings around the periphery. This provides a film of oil at all times which acts to maintain proper lubrication and to hold the compression tightly. In addition to the V-shaped groove is the step lap joint which eliminates leakage. The illustration shows that this ring differs widely from the ordinary diagonal split type.—Rittenhouse, Fleury Co., Baltimore, Md.



Rittenhouse piston ring with cross section

Stryker Headlight Deflector

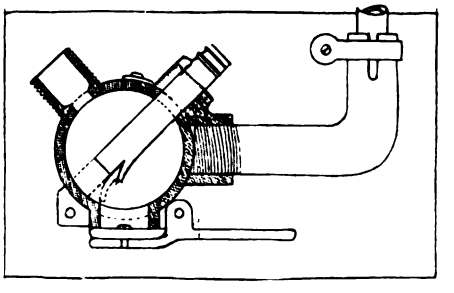
For deflecting the rays of headlights, so as to permit the rays to be thrown on the ground but not to bother pedestrians or approaching cars, the Stryker headlight deflector makes use of a bulb in which the rays of light are brought under control. As shown by the illustration, the bulb is darkened so that the reflector cannot throw the light to a height above the ground sufficient to reach the eyes of the pedestrian. The deflector can be placed on any globe and if one is broken or burned out it can be moved to another, since it is indestructible. The deflector does not dim the rays, it simply deflects them to the place where they are most needed. The price is $1 a pair.—C. L. Stryker, Buffalo, N. Y.



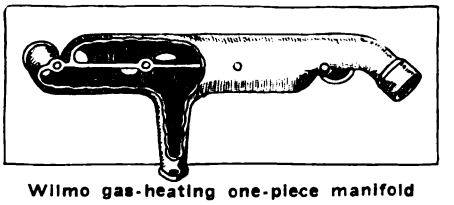
Stryker deflector on headlight bulb

Dietz Carbon Eater

The Dietz system takes water vapor or steam leaving the radiator through the overflow pipe and leads it to the carbureter, where it mixes with the gasoline and air and is carried into the cylinders. An automatic gate in the pipe line between the overflow and the carbureter prevents the passage of liquid which is drained off by a balance trap at the bottom. The makers claim that the device is a preventive of carbon, a softener of old carbon and that it makes the motor run more smoothly on less fuel. It sells for $5, installed.—Dietz Carbon Eater Co., Gray & Thomas, agents, Denver, Col.



Dietz carbon-eater separating valve



Wilmo gas-heating one-piece manifold

Wilmo Manifold

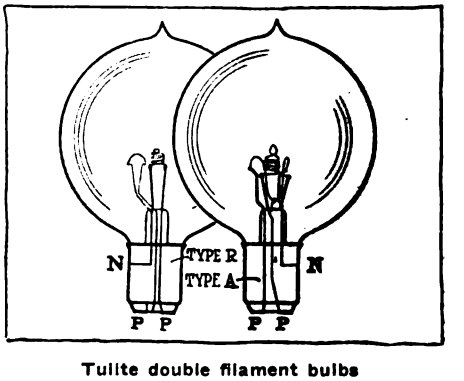
The Wilmo manifold takes both intake and exhaust gases, the two being separated only by partitions. The object is to thoroughly warm the incoming gases and so insure their proper vaporization. Special manifolds are made to fit most of the standard cars on the market and in no case is any machine or other fitting work required, the manifold fitting exactly in the place of the original. Better running and greater fuel economy are claimed for the device. Price, standard model, $10; Ford model, $7.50.—Wilmo Co., Chicago, Ill.

Tulite Headlight Bulb

The object of this bulb is to provide two degrees of illumination within the lamp itself, which is accomplished by using two filaments, either of which can be switched on. The larger filament provides full illumination and the smaller gives sufficient light to see from 40 to 75 ft. ahead of the car. The bulb is made in two types; type R is inserted with the small filament above the larger, projecting the light on the roadway at short range, while type A has the small filament mostly surrounded by the larger so that the diffused light covers a large area. In the standard bulb the candlepowers of the filaments are 4 and 20, but other intensities and combinations can be supplied.—Tulite Auto Bulb Co., Detroit, Mich.

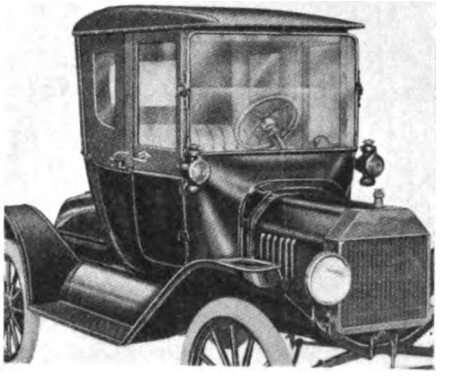
White Coupé Top for Fords

This mohair top makes use of the windshield that comes on the car, but an inner shield is built into the top at the rear of the regular shield. Two bolts secure the door of the demountable top to the car door and a hinge holds it in place at the top. Handles connect with the door lock on both inside and out. The inner shield mentioned and the windows are of heavy celluloid made expressly for the purpose and are fastened to the



Tulite double filament bulbs

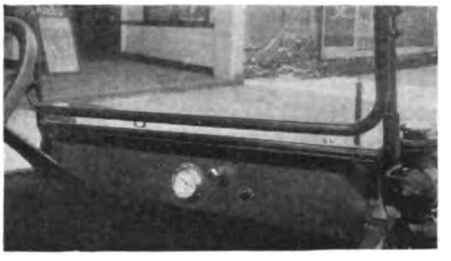
frame of the top with turn fasteners. For summer driving the side curtains and inner shield are removed and the back curtain rolled up, if desired. The door may be dismounted or left on as it is light and correctly hinged. If desired, the coupé top may be removed entirely and used only for colder weather. A fabric cowl is furnished for 1913 and 1914 models. The makers state that the top can be put on in a few hours, full directions being supplied. For 1915 or 1916 models the tops sell for $45 while for 1913 or 1914 models the price is $46. —Geo. White Buggy Co., Rock Island, Ill.



White coupé top for Ford cars

Whetstone Instrument Board

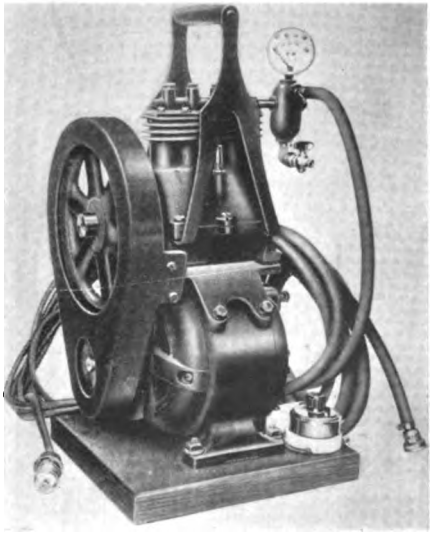
This instrument board is designed for Ford cars and is made of heavy sheet steel, reinforced. It is secured by two bolts, and the makers state that it can be attached in 10 min., the bolts used being already on the car so that no drilling is required. The clock, lamp and switch, furnished with the complete equipment, are finished in nickel. The board is enameled black, and alone sells for $1, while with clock, lamp and switch the price is $4.05.—J. H. Whetstone & Co., Lapeer, Mich.



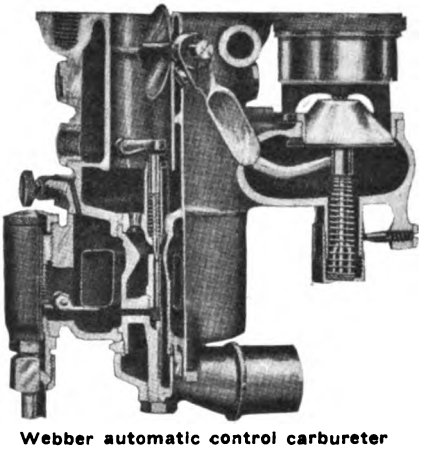
Whetstone's instrument board for Fords

Guco Garage Tire Pump

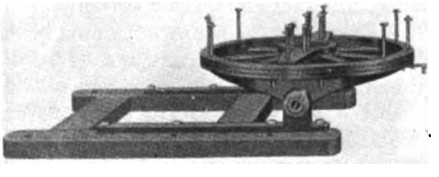
This new garage pump is a self-contained unit, mounted as shown in the illustration. A handle is supplied, allowing it to be easily carried, or it may be mounted on a small carriage, if desired. The air pump, mounted on the motor, has four cylinders, insuring a steady flow of air, the corrugations on the cylinders assisting in dissipating the heat generated and keeping the operating temperature low. Metal pistons, each with two compression rings, are used, the connecting-rods and main bearings being of bronze. The motor is the ¼-hp. standard Westinghouse type CA or CD, depending upon the nature of the circuit. All electrical contacts are shielded and all working parts inclosed, making it dust-proof.



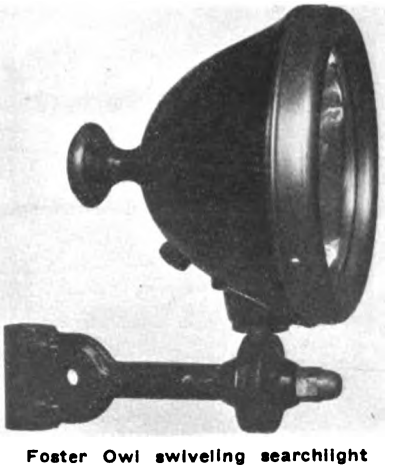
Guco power tire pump for garages



Webber automatic control carbureter



Martin's fifth wheel for trailer



Foster Owl swiveling searchlight

All parts of the pump are lubricated by splash. The complete equipment consists of a motor-driven pump, a pressure gage, an air hose, an acorn connection and a snap switch for starting and stopping the motor.—General Utility Co., Philadelphia, Pa.

Webber Carbureter

Automatic fuel control is vested in the air valve of the Webber carbureter, which is connected to the needle valve in the centrally located spray nozzle through an arm and opens the valve in proportion to the air opening. A dashpot above the air valve prevents fluttering. There are two adjustments in addition to the air-valve spring tension adjustment; one is for low speed and the other for high speed, and these are non-interfering. The richness of the mixture can be regulated by a lever on the steering column without upsetting the proportions at high and low speeds. The carbureter is intended to be used with a hot air supply, and fittings for this purpose are supplied at an extra charge. The instrument sells for 1¼ in., $30; 1½-in., $35; 1¾-in., $40; 2-in., $45.—Webber Mfg. Co., Boston, Mass.

Martin's Fifth Wheel

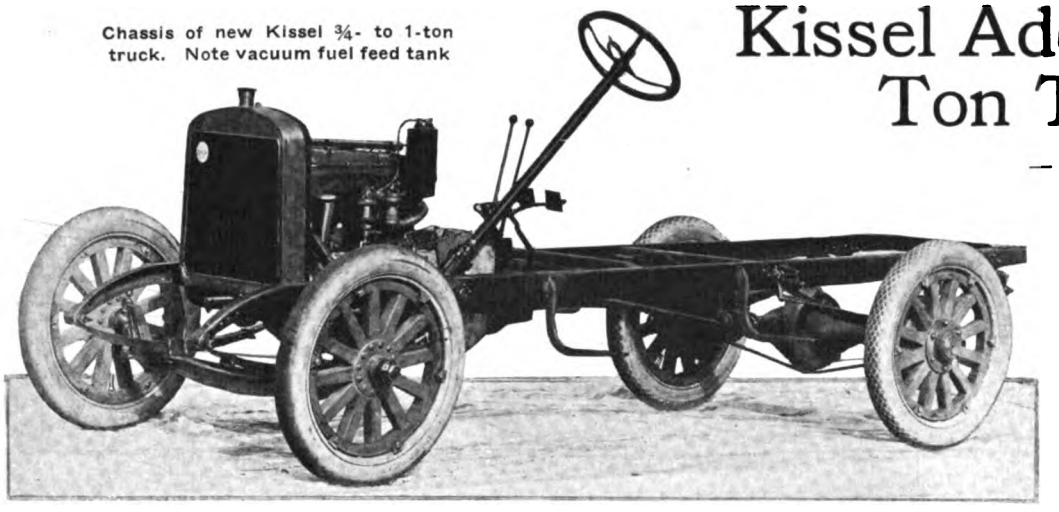
One-half of this fifth wheel is designed to be mounted under the front end of a two-wheeled trailer and the other half on the rear of the frame of the towing vehicle. The lower circle of the fifth wheel is carried on transverse trunnions so that strains due to rough roads are avoided. The springs take care of twisting tendencies. The makers state that a Ford car can handle a 1500-lb. load on a semi-trailer, the trailer wheels being so placed that the weight on the rear wheels of the car is normal and the trailer wheels carry the rest. Price, 18-in., for Fords and other light cars, $25; 32-in. for 1 to 3-ton trucks, $80, and 36-in. for 4 to 5-ton trucks, $90.—C. H. Martin, Springfield, Mass.

Foster Owl Searchlight

The Owl searchlight is provided with a swivel which permits it to turn in any direction, and which is of such size and design that it is unaffected by jolting and vibration, although easily moved by the hand. The bracket may be easily attached to any windshield without other fittings. The lamp is furnished with tungsten bulb, bracket, 3 ft. of cord and two sockets for $7.50.—C. H. Foster Accessories Co., Chicago, Ill.

Shelby Garage Door Holder

This device catches the garage door when it has swung open and holds it until released by a pull on the ring at the end of the chain. It is of wrought steel and no springs are used. Finish is black japan. Price, $1.50.—Shelby Spring Hinge Co., Shelby, Ohio.



Chassis of new Kissel ¾- to 1-ton truck. Note vacuum fuel feed tank

Kissel Adds ¾- to 1-Ton Truck

New Worm-Drive Model To Sell for $1,250—Rear Axle a Feature

A NEW departure for the Kissel Motor Car Co., Hartford, Wis., is in the shape of a new ¾- to 1-ton worm-drive truck which is to sell for $1,250. The details of the new design have just been announced and the factory has already started on quantity production and is ready for immediate delivery.

The feature of the new design is the David-Brown rear axle which has a 56-in. track and 39-in. spring centers. The worm wheel and differential are mounted as a single unit in a cast-steel carrier placed in the center housing of the axle. With this construction the weight of the truck is carried on heavy steel tubes and in the lower part of the axle housing is a spacious oil reservoir. An automatic oil level and filler plug is fitted to secure constant lubrication. One of the meritorious features of the axle is that it can be taken apart and reassembled without removing it from beneath the truck.

32-Hp. Power Plant

A Kissel power plant which is rated at 32 hp. and is built in the form of a four-cylinder motor of 3⅞ by 5½ dimensions is employed. This motor is featured by large bearing spaces to take care of heavy duty jobs and the crankshaft bearings are of white metal, steel-backed and babbitt-lined. Special gage steel is used for the valves and the entire valve action is inclosed by quickly removable covers.

An integral forging is used for the camshaft. The bearing spaces on this also are generous and the construction is so arranged that the entire shaft can be removed without disturbing the bushings. A further move towards accessibility has been made by building the crankcase in halves. The lower section can be removed without disturbing any other part. The crankshaft is supported in the upper half of the crankcase and is an extra heavy drop forging.

Lubrication is by a constant level splash system with a positively driven pump forcing the oil through tubes to the splash troughs. The oil is strained before entering the pump.

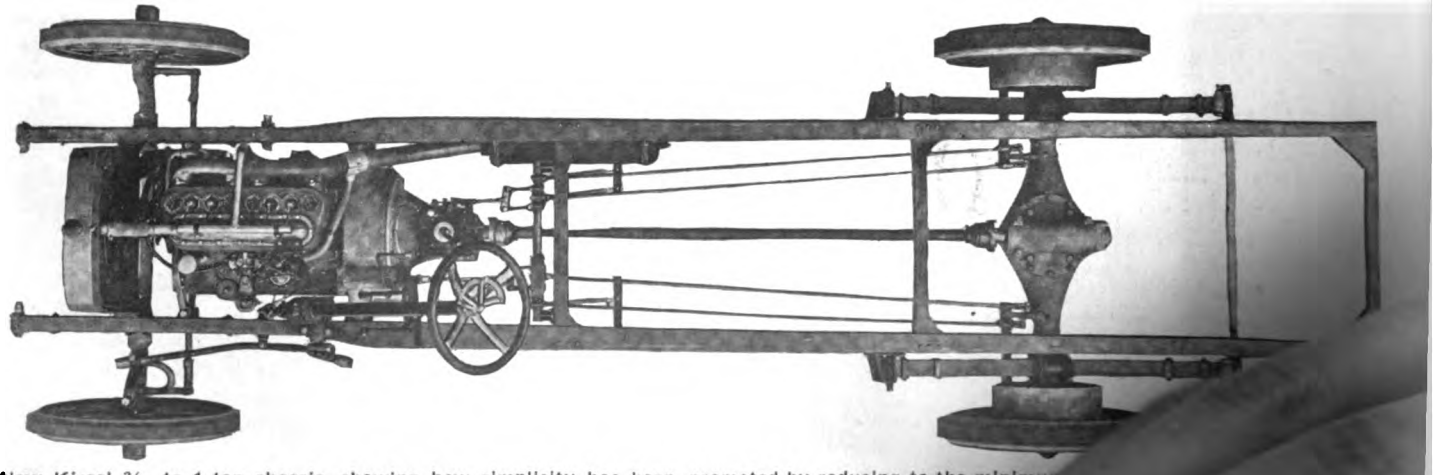
Carburetion is by a specially made Stromberg instrument of Kissel design. Owing to the use of vacuum feed accessibility is secured by mounting the carbureter quite high.

A cone clutch with leather facing and adjustable spring inserts transmits the drive. Accessibility here is secured by rendering the parts all open for inspection through the floor of the truck. The clutch and gearset are in unit with the motor and the whole plant is suspended at three points.

Simplicity in the layout of the chassis is secured by reducing to the minimum the number of operating levers. Both the foot and emergency brakes are internal expanding and both are equalized. The gearset is connected with the rear axle through a grease-packed Spicer Universal joint and driveshaft. The differential is a bevel gear design.

A feature of the truck is that the speeds are automatically governed. Twenty m.p.h. can be obtained on third or direct, 10 on second and 5 on first. The truck has a turning radius of 25 ft. which is short for its wheelbase of 125 in. The tires are optional, being either 35 by 4½ pneumatic or 34 by 3 front and 34 by 4 rear, solid. The wheels are second growth hickory and made to conform with S. A. E. specifications.

The standard express body is furnished for $150 additional. The company will also supply blueprints if a purchaser desires having the body built by local body builders.



New Kissel ¾- to 1-ton chassis, showing how simplicity has been promoted by reducing to the minimu

Tire Standardization

THE automobile tire industry is already profiting from the efforts of standardization but, while a little has been accomplished, very much yet remains to be done. Standardization has in mind at all times the elimination of waste and with some tire makers producing considerably more than 100 different models or sizes of tires, the amount of waste is considerable. This waste is the more useless when it may be possible to standardize on nine different sizes, with their oversizes. But unfortunately the entire field is divided into two grand divisions on the type of tire manufactured, whether clincher or straight-side, and were it possible to standardize on either one it would cut the number of sizes carried approximately in half. The economy in manufacture alone would be large, but there would also be the great economy of simplifying the amount of stock carried in the hundreds of cities and towns throughout the country. Instead of fighting each other on this question of clincher or straight-side, it would be better for tire maker, for tire seller, for car maker and car owner, if the tire industry would get together and definitely settle on one form of construction or the other, a condition which will eventually arrive.

There are many other problems to be settled sooner or later in the tire industry. In the solid tire field is the problem of the height of section which is at present being pushed by a few companies. Then, too, is the relative question of the pressed-on and the demountable solids. Many factors enter into both of these questions which could be simplified by the tire makers getting together with the spirit of determination to settle questions in conference rather than endeavoring to settle them by arguments disseminated by salesmen. Much has already been done to simplify the solid tire field. It was not long ago when if you changed from one make of solid tire to another you changed the wheels on your vehicle. Those days are already happily forgotten, and many of the bothersome questions of to-day can be solved with amazing speed by a business get-together; not a get-together having in mind obtaining some inside information on the other fellow, but a business get-together. This has been proved many times in other fields and there is no reason why there should be any difference in this case.

Car Comforts

THE comfort of equipment has certainly a great deal to do with the sale of an automobile, and it is sure that in the coming shows the accessory stands will display yet another crop of fittings designed to provide the greatest luxury for the occupants of the car. It has been a rule of the past that the accessory inventor should develop his ideas, that the accessory manufacturer should put them on the market, and that the automobile manufacturer should, finally, after a few years, apply them to his standard car.

We have seen this happen with the speedometer, the self-starter and electric lighting. It is in the transition stage with the demountable top that will make a true closed car from an open one and there are sundry other attachments which may come to be standard also. One such is some apparatus for warming the interior of a car, whether of the closed or open variety. We have several methods for applying the waste heat of the exhaust gas to the tonneau or the driver's compartment and with a very little more development as independent accessories there should be a place for them in standard equipment.

Another detail which is likely to be slower in coming, but may none the less be expected eventually, is the tonneau windshield, for as an aid to comfort it only needs to be tried once to be ever afterward desired. As an attachment it is possible to make it fold away with fair neatness, but as standard equipment it could be as inconspicuous as folding seats have now become.

That equipment plays a conspicuous part in selling a car is accepted as a fact, and this has stimulated the invention of thoroughly good fittings which will really be appreciated by the motorist. Probably the shows just coming will excell all others for the display of intelligent accessories of this class, and show visitors should make sure they pay proper attention to the accessory section.

Buick to Double Plant

150,000 Cars for 1917—To Enlarge All Parts and Accessory Plants

DETROIT, MICH., Nov. 23—*Special Telegram*—The plant of the Buick Motor Co., Flint, Mich., is to be doubled and for 1917 a production of 150,000 Buick cars is contemplated, or double the production scheduled for 1916. A new motor castings foundry two stories, 470 by 247 ft., with basement, will be put up at once. Additions to the drop forge plant 40 by 200 ft. are under way and further additions will be put up. Half a million dollars will be spent for this purpose and the working force will be gradually increased but this will not be done as rapidly as desired because several thousand new houses will have to be erected in Flint to house the men.

All other plants making parts and accessories for the Buick and General Motors companies will also be enlarged to increase their output facilities. When the new motor castings foundry is completed the old Michigan Motor Castings plant will become a part of the plant of the Weston-Mott Co. Three hundred Buick cars are now being built daily.

—

Crane with Lockhart in Europe

NEW YORK CITY, Nov. 23—H. M. Crane, chief engineer and vice-president of the Simplex Automobile Co., New Brunswick, N. J., has accompanied Henry Lockhart, president of the Simplex company and the Wright Aeroplane Co., on his trip abroad to study the recent developments made in aeroplane motors in England and France. Both Mr. Crane and R. B. Wasson, factory manager of the Simplex company, have joined the Wright company.

—

Work Off for Europe

NEW YORK CITY, Nov. 23—B. G. Work, president of the B. F. Goodrich Co., sailed yesterday for Europe on the Philadelphia. The trip is made in the interests of the French subsidiary of the Goodrich company.

—

Bell Delivery Car $750

YORK, PA., Nov. 19—Shipments of Bell commercial cars are being made from the plant of the Bell Motor Car Co., this city. The car is of the light delivery type capable of carrying 1200 lb. and is made with open and closed body, being mounted on the same chassis as the touring car. It is equipped with a Bosch magneto instead of the battery coil system, as used on the touring car. It has electric lights and starter, Lycoming 3½ by 5-in. motor; 112-in. wheelbase and uses Hotchkiss drive. Orders for quite a number of the cars have already been booked by the Bell company. Its price is the same as that of the touring car and roadster manufactured by the company, $750.

The work on the erection of the two large additions at the plant is about being completed. Operations in the several departments are being gradually increased and the output now averages two cars daily.

—

1916 Pullman on One Chassis

YORK, PA., Nov. 22—The Pullman Motor Car Co. will produce but one chassis for 1916 with 114 in. wheelbase, cantilever rear springs and equipped with 31 by 4-in. tires, non-skid all around on demountable rims. The motor is 3¾ by 4¼, block cast, and a unit with a multiple disk clutch and three-speed gearset. Four bodies are mounted on this chassis, these being five-passenger touring, two- and three-passenger roadsters and a coupé which is equipped with the C-H magnetic gearshift. The price of this model is $990; the others list at $740. Among the changes that have been made are the adoption of independent ignition by Dixie magneto and cantilever springs.

—

U. S. Rubber Co. to Open Lycoming Plant

WILLIAMSPORT, PA., Nov. 19—The United States Rubber Co. will shortly reopen the plant of the Lycoming Rubber Co., this city. Minor repairs are being made to the plant which will be ready for operation before Jan. 1. It is understood that the company intends to use the Williamsport plant as an "overflow" factory, that is to manufacture on a small scale certain lines which the plants of the company already in operation are not equipped to make or too busy to turn out.

—

Kenney With Hyatt Bearing

NEWARK, N. J., Nov. 19—W. C. Kenney has joined the Hyatt Roller Bearing Co. as chief mechanical inspector. Mr. Kenney comes to the Hyatt company from the Northway Motor & Mfg. Co., Detroit, Mich., where he was division superintendent. Previous to his engagement with that company he was factory superintendent of the King Motor Car Co.

—

Hood Resigns from Detroiter

DETROIT, MICH., Nov. 20—Wallace C. Hood, who has been general sales manager of the Detroiter Motor Car Co., has resigned. He was formerly sales manager of the old Briggs-Detroiter Co. Mr. Hood intends to enter another line of business.

Saxon Motor Car Corp. Now

Succeeds Co.; Capital $6,000,000 —To Increase Production —Dealers Buy Stock

DETROIT, MICH., Nov. 20—Another big event in the automobile industry of this city took place to-day. It was the announcement by President Harry W. Ford of the Saxon Motor Co., that the latter concern has been succeeded by the Saxon Motor Car Corp., which has just been incorporated under the laws of New York, and whose capital stock is $6,000,000.

The Saxon Motor Co., which started in business in November, 1913, was capitalized at $350,000 of which $250,000 was common stock and $100,000 was 7 per cent preferred stock. The entire new capital stock is common, and half of this, or $3,000,000 will be offered to the public at $75 per share, a first payment of $5 per share being required with all subscriptions. The subscription books open Monday, Nov. 22, and close Nov. 24.

Dealers Buy Stock

These $3,000,000 worth of stock were bought by a banking syndicate consisting of Merrill, Lynch & Co., of New York and Detroit. They report that Saxon dealers all over the country are buying the new issue.

"Our business has been expanding so rapidly," said president Harry W. Ford, "that we had to make it possible to greatly increase our production and prepare for the future big business, which we anticipate. We have built and shipped 17,000 cars in round figures thus far this year. Our production schedule from the end of August, 1915, to July, 1916, calls for 27,600 Saxon cars. With the increased capital we contemplate greatly increasing our production facilities and the output.

"In October we made and shipped in round figures 2500 Saxons. The November schedule calls for 2800 and in December we expect to turn out and sell 3000. The demand all over the country for our product is growing and I have no fear that the demand for automobiles in general, the lower priced cars in particular, will continue to increase. More and more is the automobile bought as a necessity rather than a matter of pleasure. That is why I believe the automobile business will continue to grow."

The officers of the Saxon Motor Car Corp. and the directors are: Harry W. Ford, president and general manager; Percy Owen, vice-president; Lincoln Scafe, secretary-treasurer. Lee Counselman and George W. Dunham, together with the officers, make up the board of directors.

Springfield Body Co. Formed

$1,000,000 Company to Operate Plant in Detroit as Well as in Springfield

SPRINGFIELD, MASS., Nov. 20—The Springfield Body Co. has been incorporated for $1,000,000 in this city to take over the business of the Springfield Metal Body Co. This reincorporation has been made necessary on account of increased business which has shown a gain of 3000 per cent in the last 120 days.

Plans are now under way for a plant in Detroit which will be used for large orders, while the Springfield plant will be used for small orders.

Hinsdale Smith of Holyoke and A. P. Smith of Granby, the owners of the old company, are included in the list of incorporators with W. L. Fry of New York, E. W. McGookin of Detroit and F. W. Fuller of Springfield.

W. L. Fry has been elected president of the company; Hinsdale Smith, vice-president and chief engineer; E. W. McGookin, vice-president and director of sales; and A. P. Smith, treasurer. Mr. Fry became interested in the company about a year ago and was instrumental in the organization of the new company.

Both Hinsdale and A. P. Smith have been in the automobile business for some years. The Springfield Metal Body Co. was incorporated with a capital of $20,000 in 1905, occupying the old Boston & Albany shops until it moved to Brightwood, where the company owns and occupies three large buildings.

The new stock is divided into $250,000 preferred and $750,000 common. This will probably not be placed before the public, but taken by the trade.

—

A New Motor Company

CANTON, OHIO, Nov. 19—The Ohio Motor Co., a new concern backed by Canton, Springfield and Toledo capitalists, has decided to locate a factory for the manufacture of motor devices and accessories in this city. A site will be secured and a factory 60 by 600 ft. will be erected. One of the specialties to be manufactured is motors for motor trucks, tractors, and aeroplanes.

Steps have been taken to incorporate the concern with an authorized capital of $500,000 of which $200,000 will be paid in.

—

Landis Buys Flinchbaugh Mfg. Co.

WAYNESBORO, PA., Nov. 19—The Landis Tool Co., Waynesboro, Pa., this week purchased at private sale the plant of the Flinchbaugh Mfg. Co. of Greencastle. The price paid was $42,500. The Flinchbaugh company, which was engaged in the manufacture of gasoline engines and tractors, moved from York to Greencastle two years ago and was financed by citizens of Greencastle and vicinity.

The Landis Tool Co., employing 800 persons, manufactures the Landis shock diffuser and other automobile accessories. The company has been rushed with work for the past two years. Last Saturday the employees were given an increase of 1 cent an hour.

—

Hupp Buys American Gear Plant for Axle Plant

DETROIT, MICH., Nov. 22—A deal involving $1,000,000 was completed to-day whereby the Hupp Motor Car Co. acquires the plant and property of the American Gear Co., Jackson, Mich. This is part of the expansion movement started by the Hupp company in conjunction with the recent increase of its working capital.

The Jackson plant has been taken over by the Hupp company and will be known as its axle plant. Dubois Young, who was factory manager of the American Gear Co., will continue with the Hupp organization in the capacity of general works manager. The plant has been employing several hundred men.

Further announcements will be made by the Hupp company concerning further expansion as soon as the details are completed. Plans are being made for a greatly increased production.

—

Reisinger Argo Purchasing Agent

INDIANAPOLIS, IND., Nov. 20—N. B. Reisinger, who has been purchasing agent for the Pathfinder Co., this city, has resigned and accepted a similar position with the Argo Motor Co., Jackson, Mich. Mr. Reisinger was for many years connected with the old Stoddard-Dayton Co., before joining the Pathfinder Co.

—

Brockway Truck Adds to Plant

CORTLAND, N. Y., Nov. 18—The Brockway Motor Truck Co., this city, has purchased nearly an acre of land east of its present plant and has begun work on the foundations of a new building 186 ft. long and 40 ft. wide. The second building will be added in the spring. The buildings are of concrete block.

—

Heads Los Angeles Speedway

LOS ANGELES, CAL., Nov. 20—W. M. Garland has been elected president of the Los Angeles Speedway Association, which is capitalized at $1,000,000. Construction on the 2-mile board track in this city has been started.

Hupp Capital Now $6,500,000

Increased from $1,000,000—$5,000,000 Is Common and $1,500,000 Preferred

DETROIT, MICH., Nov. 19—The Hupp Motor Car Co. has increased its capital stock from $1,000,000 to $6,500,000. Negotiations to that effect had been under way for some time and the re-financing deal was made with the New York bankers Ladenburg, Thalman & Co., and with A. G. Becker & Co., Chicago bankers.

Of the new capital $5,000,000 is common stock and $1,500,000 preferred. Previous to the increased capitalization the entire capital stock of the company was common stock. It is stated, but not confirmed by officials of the Hupp company, that present common stock shareholders will receive a common stock dividend, but no cash dividend. There is also to be a distribution of common stock as bonus to go with preferred stock, but in what proportion this will be, has not been stated.

The Hupp Motor Car Co., was organized in the Spring of 1908, its capital stock being $25,000, and it leased a plant on Bellevue Avenue. Ever since, the business has grown, necessitating the gradual increase of the capital stock while a larger plant was put up first on Jefferson and Concord Avenues and later at Mt. Elliott and Milwaukee Avenues, the present location.

Additions were started some time ago to further enlarge the plant as the production facilities are still inadequate. For the season 1916, the company had planned an output of 15,000 cars, but, according to President J. Walter Drake, this is to be increased.

—

Crow Gets Big Export Order

ELKHART, IND., Nov. 20—The Crow Motor Car Co., this city, is preparing to turn out a new roadster called the Crow-Elkhart Clover Leaf Roadster. Five hundred of the cars have been ordered by a distributing agency in London. The car is built on a low model with three seats in the shape of a clover leaf. It sells for $785.

—

Chevrolet Assembly Plant for Dallas

DALLAS, TEX., Nov. 19—It was learned authentically in Dallas to-day that the Chevrolet Motor Co. will build in Dallas an assembling plant similar to the Ford assembling plant. It is said $250,000 will be spent on the Dallas plant and that several hundred men will be employed. A site in East Dallas has been secured.

Autocar Doubles Capital

Now $2,000,000—Sales Increase 70 Per Cent in Last Ten Months

PHILADELPHIA, PA., Nov. 20—The Autocar Co., Ardmore, Pa., has increased its capital stock from $1,000,000 to $2,000,000 to provide for doubling its manufacturing facilities and output of trucks and to provide for its rapidly expanding business. According to a statement issued by the company, sales have increased 70 per cent during the past ten months over the corresponding period a year ago, this being entirely due to the growing domestic demand, the company having no war orders. The new stock, which, like the original capital, is all common, is being closely held by the original founders and their associates. There are over 3000 owners of Autocar trucks at the present time.

—

Four Gary Trucks ¾ to 2 Tons

GARY, IND., Nov. 20—Gary motor trucks, made by the Gary Motor Truck Co., this city, are produced in four models of ¾, 1, 1½ and 2 tons capacity, all of practically identical build excepting in size of main parts. They are of standard form throughout, employing Buda unit power plants and worm drive, with European motor location and left steer and control. Their general construction is:

Capacity	¾-ton	1-ton	1½-ton	2-ton
Price				
Wheelbase	118	128	135	144*
Tires, front	36x3	36x3½	36x3½	36x4
Tires, rear	36x3½	36x4	36x5	36x6
Drive	worm	worm	worm	worm
Bore	3½	3¾	3¾	4½
Stroke	5⅛	5⅛	5½	5½
S.A.E. hp	19.61	22.5	22.5	29
Speed, m.p.h.	15	15	15	15

*135 optional.

Eisemann high-tension single ignition, with fixed spark is employed and a Stromberg carbureter. All motors are furnished with governors.

Sheldon Worm Axles

Dry disk clutches, faced with Raybestos take the drive from the motor to the three-speed selective gearset amidships, on each model, from which the drive is taken by single shafts with two universals each to the Sheldon worm-driven rear axles.

Goodyear S. V. solid tires are standard, although pneumatics will be fitted if ordered.

—

10,886 on Packard Payroll

DETROIT, MICH., Nov. 19—A few days ago the payroll of the Packard Motor Car Co., showed that 10,886 men were working at the plant. Less than three months ago the number was 8200, while on Aug. 21, 1914, when representatives of the Department of Labor of Michigan, visited the factory, there were 4387 men and women in the employ of the company. This is mentioned to show how the Packard business has been growing and has made it necessary to increase its working force more than 50 per cent within one year. This increase in the number of men employed is expected to continue as the payroll for November is scheduled to be more than $800,000 while in October it totaled $773,879.

During October 477 carloads of material and 3,273,560 lb. in less than carload lots were received at the plant.

—

Employers in New National Body

NEW YORK CITY, Nov. 18—The nineteenth annual convention of the National Founders' Association, opened to-day in this city at the Hotel Astor. While the session was executive, the speakers unanimously agreed that the time had come when the industrial interests of the United States should join in a common movement to insure a successful foundation by acquainting legislators and the people at large, through one organization, as to their legitimate needs. The plan upon which it is proposed to organize the employing and manufacturing forces of the country into one central organization has not been disclosed in detail, but is said that it contemplates the combination of the employers of labor in the industrial plants throughout the United States with special committees selected from all to take up and deal with one particular object such as foreign trade, the tariff, wages, etc.

—

Pontiac Car Builders Prosper

PONTIAC, MICH., Nov. 18—According to reports from four local banks, their total commercial deposits on Nov. 10, showed a gain of $313,681.45 over the total on Oct. 31, 1914. The total saving accounts showed a gain of $285,460.46 for the same period. The total deposits in these four banks were $5,743,922.64 Nov. 10, as compared with $5,144,780.83 at the end of October, 1914. According to officials of the banks, this increase in bank business is due principally to the bigger business of the local automobile and parts manufacturing concerns.

—

Detroit Cos. Increase Capital

DETROIT, MICH., Nov. 19—The capital stock of the Columbia Castings Co. has been increased from $30,000 to $100,000; that of the Christie-Kline Forge Co., from $3,000 to $10,000 and the capital stock of the O. K. Motor Truck Co., from $10,000 to $25,000. The latter company's name has been changed to that of Lincoln Motor Truck Co.

Materials Still Scarce

Tungsten, at Present Unobtainable, Raises Cost of High-Speed Steel

DETROIT, MICH., Nov. 20—The scarcity of materials, either raw or finished, needed by automobile and motor car parts manufacturers, does not seem to be improving, although in some quarters it is claimed that the situation is now better than what it was a month or two ago. As a matter of fact, it does not seem possible and likely that this condition will improve as long as so much war material is being made in the country for the nations at war. As one local purchasing agent said, there would hardly be any scarcity of any material if no motor trucks would be exported and as the exports of trucks alone is nearly ten times in number what the exports were a year ago, there may be some truth in the remark.

A man who is familiar with the situation and who, on account of the big business his firm does, might be called on to speak with authority, is W. H. H. Hutton, Jr., director of purchases at the Timken-Detroit Axle Co. Speaking on the subject generally and of high-speed steels in particular, Mr. Hutton said:

Every piece of high-speed steel used in the making of drills and other tools to cut iron and steel contains about 20 per cent tungsten, and as tungsten is a German and an Austrian product, and therefore unobtainable at the present time, high-speed steel is becoming more costly every day. This scarcity of this metal is really alarming when judged from the motor car manufacturing viewpoint.

"For instance, at the present time if we went on the open market we would have to pay over five times more per liter for high grade steel than we did at the beginning of the war. And the grade of steel would be far inferior to any we ever bought before, in fact it would hardly compare to the very poorest grades offered for sale in this country under normal conditions. Not only are we now paying much more for what we are getting, but we are having a very hard time to get any at all.

"Take drills made of this steel, for instance. To-day we are paying about four times the normal price for ½-in. drills and about five times the normal price for inch drills. Not only are the supply houses quoting these steels at the list price, minus discounts formerly offered, but they ask a high premium over and above the present list.

"This condition does not apply to high grade steels solely, though. Other elements that are extensively used in the

manufacture of motor cars and motor car parts are equally if not more scarce. Antimony has jumped six times its normal value. Aluminum has raised 300 per cent while there is a decidedly rising market on copper, tin and spelter, commonly known as zinc.

"The tin market, however, will soon be in much better shape than it is at the present time. Big ore men in this country have recently opened large furnaces in the east to smelt Ecuadorian tin and this will relieve the tense situation on that product if it does not bring it back to normal.

"There is a little antimony being mined now in Death Valley, Southern California, but the price of labor and bringing it out of the railroads is so high that it has not had much effect on the price of the refined article as yet.

"Should the war continue much longer, American manufacturers must find some way of procuring these essential elements, or manufacturing efficiency will be greatly handicapped. We must have these elements. Now is a good time to start producing them commercially in this country."

—

Sun Moves to Elkhart

SOUTH BEND, IND., Nov. 22—The deal has just been consummated by which the Sun Motor Car Co., Buffalo, N. Y., purchased the two factory buildings formerly occupied by the Sterling Motor Car Co., Elkhart, Ind. The consideration was $30,000. The Sun company will begin the installation of machinery at once. The new company which was incorporated at Buffalo last July, will manufacture the Sun light six to sell under $1,000. The officers of the company are: R. Crawford, president and general manager; J. P. Black, secretary and treasurer; M. H. Pittman, director; Roscoe C. Hoffman, chief engineer; S. A. Merinbaum, sales manager; H. A. Minturn, advertising manager; John L. Larkin, assistant to general manager. All of these men are residents of Buffalo, with the exception of Mr. Black and Mr. Pittman, who are residents of Chicago and Mr. Hoffman, who is a resident of Argos, Ind. It is the intention of most of the officers and heads of departments to move to Elkhart. The first machinery has been ordered for delivery Dec. 15, and it is expected to have the machinery installed soon after that time to begin operations. Two to four hundred men will be employed.

—

Nash as Guest of Honor

FLINT, MICH., Nov. 20—Charles W. Nash, president of the Buick Motor Co. and of the General Motors Co., has been invited as the guest of honor of the semi-monthly dinner of the Board of Commerce of Flint, to be given Nov. 23.

Weight Is Subject of N. Y. S. A. E.

—

Gasoline Electric Committee Reports Progress—Analysis of Types—50 at Session

NEW YORK CITY, Nov. 19—At the meeting of the Metropolitan Section of the Society of Automobile Engineers held at the Automobile Club of America last night a report of the gasoline-electric research committee and a paper on Car Weight in Relation to Acceleration were read. The report of the committee was given by each of the members individually covering different sections of the work. David Beecroft, chairman, gave a summary of the activities of the committee, L. G. Nilson, president Nilson-Miller Co., gave an analysis of the different types examined and a description of the Thomas system and W. P. Kennedy described the wiring and circuits under different conditions in the Owen Magnetic car. The paper on acceleration consisted of miscellaneous notes made by A. Ludlow Clayden based on observations on the acceleration of three typical cars.

The Thomas System

The description of the Thomas system which is in extensive use in England was secured on the occasion of the recent visit of Hedley T. Thomson, one of the managing directors of the company, to this city. This drive, which employs two electrical machines with a planetary gearset interconnecting them, is being successfully used in Europe for heavy units. On railway cars having to climb grades of 2½ per cent with maximum load at 10 m.p.h. these systems have proven to be a success.

As the speed of the vehicle increases the speed of the first electrical machine increases while the speed of the second machine decreases until at half speed, the speed of the second machine which has been in a negative direction reaches zero and then after this time increases in positive speed until finally at maximum vehicle speed both electrical machines are running at engine speed. At maximum vehicle speed, since the two electrical machines are running at equal speed with the motor, the whole system can be connected by means of a jaw clutch, giving solid drive throughout.

Another electrical system known as the Autolectric has been discovered by the committee in addition to the previous classifications and a new sub-division will have to be made for it.

Autolectric—A New System

The distinctive feature about this system is that at starting it is purely an electrical transmission while after a certain vehicle speed has been reached it automatically becomes electro-mechanical. The battery is at all times available for starting the engine or running the vehicle without the engine and it can be charged from the dynamo with the vehicle stationary. The motor also automatically becomes a generator and can be used for braking when the vehicle is coasting, the current produced by the motor being supplied to the battery.

With the Thomas transmission the motor speed is theoretically intended to remain constant. The various units of the transmission vary in their speed in accordance with the speed of the vehicle. Owing to the planetary gearing, the second electrical machine runs at the same speed as the engine but in the opposite direction when first starting. At this time the first electrical machine remains still.

Acceleration vs. Weight

At the conclusion of the gasoline-electric committee's report A. Ludlow Clayden read some notes on the observed acceleration of three cars which he said had been tested extensively on the same speedway. He produced tables and diagrams showing the relative power of each car, measured in tractive force between the tire and the road throughout the range of speed of 10 to 50 m.p.h. over which all three cars were tested. He then gave the results of calculating the total amount of work produced by the motor of each car during acceleration from 10 to 50 m.p.h. and compared this with the amounts of power needed to produce the observed acceleration supposing there were no mechanical or air resistance. From these two sets of figures it was made obvious that the lightest of the cars had a large amount of excess power, by reason of its lighter weight. It also appeared that the resistance of the cars through mechanical and air friction varied very greatly, in other words, the air and mechanical resistance which might have been expected to be the same for three cars of closely similar size actually proved to be variable by a large amount.

A Formula Wanted

The author asked for comment on the results which might lead to additional subjects which might be studied, having a bearing on the matter, stating it to be his ambition to discover a formula which would be useful to engineers in laying out a car with a certain acceleration performance as their ideal. To discover what is the inter-relation between the weight, the horsepower curve, the gearing, etc., and the acceleration. It was stated that the author's intention was to complete a paper in proper form in a few months and he asked for suggestions that would help him in his at-

tempt to discover something which engineers would find really useful.

Carburetion a Factor?

Several of the members who entered the discussion were of the opinion that carburetion would have much to do with the final results obtained. Herbert Chase, engineer of the Automobile Club of America, stated that he had noticed in block tests that whereas two motors may have the same horsepower curves the acceleration figures would differ owing to varying carburetion. It was also brought out that accurate drawbar pull figures would help in securing a clue to the performance of the car and would show how much of the lost energy was consumed in the car and how much through the motor.

Parry Co. to Build Commercial Bodies, Tops and Trailers

INDIANAPOLIS, IND., Nov. 20—The Parry Mfg. Co., this city, manufacturer of horse-drawn vehicles, has developed a line of commercial bodies for automobile chassis, as well as two models of trailer and a variety of tops of all styles. The chief activities of the company in its commercial body line have been directed toward designs for the Ford chassis, although bodies for other makes are not to be neglected. The trailers are a two-wheeler and a four-wheeler, the connection provided being an adaptation of the Bradley coupler, permitting a straight pull on both ends of the axle that adapts itself to the motion of the vehicle to which the trailer is attached. These new lines will not interfere in any way with the manufacture of the company's horse-drawn vehicles.

Babcock to Build Commercial Bodies for Fords in Quantity

WATERTOWN, N. Y., Nov. 20—The H. H. Babcock Co., this city, is building commercial bodies for Fords in thousand lots on the unit plan. There are eight different types, to fit every requirement in light delivery service, built up from one standard body-base by adding units. The bodies are delivered painted, complete with all fittings and ready to assemble.

Gobron, French Car Maker, Killed

PARIS, Oct. 28—Jacques Gobron, one of the partners in the Gobron Automobile Co., of Billancourt, near Paris, is reported killed in an aerial fight with a German machine. He held the military rank of lieutenant and joined the French air forces at the outbreak of war. Jacques Gobron was responsible, with his brother Jean, for the Gobron automobile factory, their father, Senator Gobron having died a couple of years ago. The company was very prominent, in the early days of the industry, for its double-piston motors.

Order 21,382 New 6-30 Chalmers

600 Dealers, in Record-Breaking Convention, Find 288 Demonstrators Ready

DETROIT, MICH., Nov. 19—Six hundred dealers representing the Chalmers Motor Co. in all parts of the country took the city by storm, and they are said to have contracted for 21,382 of the new Six-30's before they left. This is more than the factory can produce up to next June, as President Hugh Chalmers promised an output of 18,000 between now and then.

Three very full days of fun and business for the Chalmers representatives ended with a banquet at the Detroit Athletic Club to-night, and it was a fitting climax of a convention which was undoubtedly the largest of its kind ever held here, if not in the industry. An army of the new Chalmers sixes transported the dealers to and from the factory and the hotels, and everything was done for the visitors to make their stay profitable and enjoyable.

Starting on Monday morning, Nov. 15, with an opening address by President Chalmers, the convention was well under way the first day. A dinner in the convention hall of the Pontchartrain Hotel ended the opening day; on the following evening a beefsteak dinner and smoker was held at the Statler Hotel; and Mr. Chalmers' closing address on Opportunity at the banquet at the Athletic Club was the parting word.

Roadster Out April 1

Paul Smith announced that a roadster will be supplied on the same chassis as the touring model Six-30 on April 1.

A feature of the convention was a parade of 288 of the new Six-30 cars and enough other Chalmers cars to bring the total in line to over 300. This long line of machines coursed through the main streets and boulevards of the city in the afternoon of the first day, following the opening session at the factory when the new model was revealed to the dealers. It is said that this is the largest number of cars that a manufacturer has had ready in the history of the industry on the occasion of the coming of the dealers. Following the opening session, the doors were thrown open and the dealers saw before them the long line of nearly 300 cars. Each car was tagged with the name of the dealer to whom it was allotted as a demonstrator, and the men had a merry time finding their own cars. It was like a gigantic dinner party, at which each guest must hunt for his place card.

In addressing the dealers Hugh Chalmers gave them due credit for the part they have played in the development of the Chalmers company. Eight years ago it was started here with a capital of $150,000, and to-day it has a capitalization of $8,000,000, and occupies twenty-four buildings on 26 acres of ground.

"Since we last met at Cedar Point a year ago last July," said Mr. Chalmers, "much has happened in the world. At that time the entire world was at peace. Now about three-fourths of the civilized world is engaged in warfare. Much as we deprecate this war, and would pray God it may end soon, it isn't of our making, and it isn't within our power to stop it. I think we should all pause for a moment and thank God that we are American citizens; and, in the second place, we ought to be thankful that we are engaged in an industry that commands the respect of the entire country, because it has proved in these troublous times that it is not of mushroom growth, but is one of the real, stable industries of the time, and it has done much to steady the hand of business during these disturbed days.

Existence Enforces Progress

"Not only have we seen great world changes in the last sixteen months, but we have seen great changes in our own automobile industry, and while it has been a prophecy for a long time that the automobile business would result in a survival of the fittest, this is no longer a mere prophecy; it is a reality to-day. It is no longer possible for a company to stand still in this business, because to stand still is to retrograde. I believe that the successful companies must continue to grow bigger or else go out of business, because competition is going to be even keener in the future than it has been in the past.

Selling Most Important

"There are four great elements in the manufacturing business. These are selling, making, recording and the management forces. While I do not wish to minimize the difficulties of making or recording, or of the management, yet I can truthfully say that selling is the most important part of any business. The reason for it is quite apparent if you will study the question for a few minutes. If we make one car right, we can from that model make 1,000,000 just like it, if we choose to do so, because the making of these cars is wholly within our control. We buy the materials, put up the buildings, buy the machinery, employ the men, raise the capital, or borrow it, and with these things we can create what is called a manufacturing plant. But this plant would be a mere tombstone in activity if it were not for the selling force which makes it possible for the wheels to run."

Isaac F. Marcosson, a noted writer and lecturer, when speaking before the

Chalmers men on the subject of The War and Salesmanship, said in part:

"Undoubtedly the most impressive feature of the foreign conflict and one that stands out as the single big lesson of the war, is the value of preparedness. The Germans were prepared for the great business of war. When they started the war, they had the map of every country in the world literally under their hats. Before the war cloud ever appeared, they had exhibited similar traits in their business transactions with the rest of the world.

"When they started out to conquer the commerce of the world, they first found out what their customers wanted and gave it to them. They knew their market, and sent out men who spoke the language of the countries in which they marketed their goods. Furthermore these men lived in their adopted countries and became a part of the commercial fabric.

"Contrast the conditions in England at the outbreak of the war with those in Germany at the same period. Here unpreparedness is as great a lesson as Germany's preparedness.

War at Motor Car Speed

"It is hard for us to realize the part the motor car is playing in the war. Without motor cars, the war could never have been carried on in its present scale. Wherever you go in Europe, you find the war geared up to the motor car.

"The war has taught us a great lesson in civilization. I am glad to see that business is neutral—there is no creed in salesmanship. We are at present on the verge of a great era of prosperity, and all conditions point to the fact that the great business of the future will be the defensive of peace, instead of toward the offensive of war."

—

Becker Is Lakey Foundry Manager

MUSKEGON, MICH., Nov. 20—With the appointment of Herman A. Becker, as general manager of the Lakey Foundry Co., this company will enter upon a new era of expanding its business. A new machine shop to take the place of the present one will be started at once. It will be constructed around this old shop in order not to interfere with the business of the company, which is growing with considerable rapidity.

Mr. Becker comes from the Rutenber Motor Co., Marion, Ind. Previous to his connection with this concern he was with the Allis-Chalmers Co., Milwaukee, Wis., for fourteen years.

—

Foundry Buys Havers Plant

PORT HURON, MICH., Nov. 17—The plant of the defunct Havers Motor Car Co., has been purchased by the Romeo Foundry Co.

Henry Ford & Son Is Tractor Firm

Profits To Be Divided Among Plant Workers and Tractor Buyers

DETROIT, MICH., Nov. 20—The Ford tractor will be made by the firm of Henry Ford & Son, Dearborn, Mich. So it was stated by Henry Ford. There will be no stockholders and the profits of the company, at least a large percentage, will be divided among the workers of the plant and among the purchasers of the tractors, it being intended to sell them under a profit-sharing system.

The big new main plant which is to make Dearborn known a little better throughout the country and the whole world and which is to supersede the present old factory buildings, is to be a four-story building, 160 by 800 ft. Several small buildings which will be a part of the whole works have been under construction for some time, as for insctance the power plant and the pattern shops, the latter now being completed.

Several hundred thousand dollars will be expended in making the plant the biggest and best equipped tractor plant in the world. It is stated that Mr. Ford will invest up to $1,000,000 in the plant.

—

Industrial Mfg. Co. Formed

MILWAUKEE, WIS., Nov. 20—The interests owning the Industrial Controller Co., this city, have organized a separate company, known as the Industrial Mfg. Co. to do tool, gage and die work for outside concerns, and make a specialty of such jobs for motor car and truck builders. The regular line of work, electrical and other controlling devices, will not be discontinued, however, as the company has orders to keep it busy for more than twelve months. The works are well equipped and additional machinery will be installed as needed. The owners of both concerns are Charles G. and James B. Welch, formerly of the Welch Bros. Motor Car Co., state agents for the Packard, and Frank W. Magin, engineer and designer. The Industrial Manufacturing Co. is capitalized at $50,000 and headquarters will be in the Controller company's offices and works.

—

Newman to Entertain 1400

MILWAUKEE, WIS., Nov. 20—Harry Newman, Inc., Chicago, Ill., appointed distributor of Chalmers cars in Wisconsin, Upper Michigan and southeastern Minnesota, announces that although Mr. Newman will take personal direction of the new business, Stanley E. Comstock, formerly with the Thos. B. Jeffery Co., will be general sales manager, with Snow E. Williams, Chicago, as assistant sales manager. A. H. Speulda, Chicago, will have charge of the business department of the headquarters and service station, now being established in the former packard garage at Grand Avenue and Seventh Street, Milwaukee.

Mr. Newman has issued invitations to 1400 dealers of the territory, to be his guests at Milwaukee on Friday, Dec. 3, which is designated Newman Day. The object of the assembly will be to discuss ways and means for the betterment of conditions in the trade and to establish friendly relationships among dealers. Mr. Newman will tender a banquet to the visitors on the evening of Dec. 3 at the Hotel Pfister.

—

Berger Is Manager of New York Lozier Branch

NEW YORK CITY, Nov. 22—L. B. Berger, Lozier factory sales manager, has also been appointed manager of the New York branch. Previous to his connection with the Lozier company he was with the Willys-Overland company in charge of Willys-Knight sales. He has installed a service system which allows any new owner of 50 hr. of free service. A book is issued containing 100 ½-hr. coupons and these are good at any time.

—

Simms Additions Under Way

EAST ORANGE, N. J., Nov. 19—Two concrete and brick additions to the plant of the Simms Magneto Co., Bloomfield, N. J., are well under way. One building will be 42 by 70 ft. and will contain the grinding and dipping departments, while the other is 72 by 90 ft. and will house the storage and shipping departments. The additions became necessary to make way for more machinery in the main factory, the entire output of the plant being contracted for well into 1916.

—

Baird Saxon Manager in New York

NEW YORK CITY, Nov. 22—Frank S. Baird has become retail sales manager of the Saxon Motor Co. of New York. He was formerly with the Chevrolet Motor Co. in the sales department. H. C. Turner has also joined the New York branch, coming from the Saxon factory.

—

Carpenter Represents Pierce in Brooklyn

BROOKLYN, N. Y., Nov. 20—H. L. Carpenter has become associated with the Pierce interests and the Harrolds Motor Car Co., representing both the passenger car and trucks of the Pierce-Arrow company in Brooklyn and Long Island.

—

Fafnir Bearing Branch in Chicago

NEW BRITAIN, CONN., Nov. 22—The Fafnir Bearing Co., this city, has recently opened a new branch office at 39 South Clinton Street, Chicago, Ill., with D. D. Davis as manager.

79,759 Cars in Wisconsin

26,600 New Cars Bought in 1915—Expect 80,000 Registrations by Dec. 31

MILWAUKEE, WIS., Nov. 20—Wisconsin automobile registrations by private owners for the calendar year ending Dec. 31 will aggregate approximately 80,000 or 5000 more than anticipated at the beginning of the year. At the close of business on Nov. 18, the Secretary of State's office in Madison reported a total issue of 79,759 licenses to private owners, or only 241 shy of the coveted figure, 80,000. It is considered hardly possible that there will be 241 more licenses issued before the end of the year, when all licenses expire. However, applications have been coming in at the rate of fifteen to twenty-five daily since Nov. 10. On Oct. 25, the total registration was 79,100, showing that between Oct. 25 and Nov. 18, 659 licenses were issued. These figures do not take into account the registration by dealers, of which there are 1581. The motorcycle registration is 8579. Private owners pay $5 as the annual fee, regardless of the period during any calendar year that application is made. Dealers pay $10 per annum, and receive four sets of license plates. Motorcyclists pay $2 per annum.

The total registration of private owners for the year 1914 was 53,161. On the basis of figures issued Nov. 19, the gain for 1915 already is 26,598, or nearly 1600 more than conservative estimates of the probable gain made at the beginning of the year. This goes to prove that Wisconsin absorbed approximately 26,600 new cars during 1915, inasmuch as licenses are annual and licenses are transferable on the sale of the car to hold good on the new car, and the purchaser of the old car is required to take out a $5 license.

—

Boston Dealers Win Fight Against Bad Law

BOSTON, MASS., Nov. 20—Boston automobile dealers have won their fight against the law that was being enforced to class them among the junk-dealers and pawnbrokers. It started a few weeks ago when the police officials went about among them and requested that each one take out a license at $5 to do business in second hand cars, and they were notified not to sell any cars that they took in before thirty days. The dealers refused because it would be a very serious hardship to them.

So acting under orders one of the police officials arrested F. A. Hinchcliffe, manager of the New England branch of the Winton Motor Car Co., charging him with refusing to take out a license, and also with the selling of a car before the thirty-day period expired.

The Boston Automobile Dealers' Association decided to fight the case for Mr. Hinchcliffe, and so their attorney John B. Sullivan, Jr., appeared for him. The attorney showed that the intent of the law was to protect people from disposing of small things that had been stolen, not motor cars. He also showed that by paying a license to the State to do business as motor dealers they could not be expected to pay another license to the city of Boston, as no other class of people have to pay two licenses to do business. After hearing the argument by the police attorney the judge stated that there was no violation of the law and discharged Mr. Hinchcliffe.

—

Commercial Agency Liable for Misleading Credit Reports

NEW YORK CITY, Nov. 20—The Appellate Division decided here this week that the Bradstreet Co. is liable to its subscribers for damages sustained when misleading information is furnished to them by the company. The case is of importance to all concerns depending upon commercial agencies for information concerning the credit of customers.

The case was that of A. J. Munro, a fur dealer, who lost $1,650 on furs delivered to the firm of Jackson & Sulzer, now bankrupt. Depending upon information concerning the firm supplied him by the Bradstreet Co., Munro extended credit to Jackson & Sulzer who shortly after were petitioned into bankruptcy.

The Bradstreet Co.'s defense stated that its contract with Munro absolved it from any responsibility for errors in information furnished concerning the standing of a commercial house. Justice Laughlin, writing the prevailing opinion, concurred in by Justices Dowling and Scott, says in part:

"A reasonable construction of the agency contract, I think, is merely to relieve the defendant from errors and mistakes, but not from knowingly making a false report, or gross mistake, or gross negligence in making a report to the plaintiff."

—

Missouri Registrations Gain 45 Per Cent

JEFFERSON CITY, MO., Nov. 19—In the nine months ending Nov. 1, 20,804 more automobiles were registered in Missouri than in the whole year of 1914. This increase of about 45 per cent is shown in figures given out at the office of Secretary of State here to-day.

Last year a total of 54,489 motor vehicles were licensed in Missouri. In the first nine months of the current registration year, 75,293 licenses were issued. Of these, 15,199 went to St. Louis and 9,168 to Kansas City. One-third of the total are owned by farmers.

Co. To Build Cars and Tractors

Corliss Steel Co., Racine, To Also Make Gas Engines, Tools and Metal Products

RACINE, WIS., Nov. 20—The organization of the Corliss Steel Co., Racine, Wis,. with a capital stock of $10,000, is believed to be the preliminary step in the establishment of a large automobile, tractor and engine business. The promoters of the new company are all well known in the motor car industry, being F. Lee Norton, for many years vice-president and general manager of the J. I. Case T. M. Co., Racine; Capt. William Mitchell Lewis, former president of the Mitchell-Lewis Motor Co., Racine, and Herbert F. Johnson, also of Racine.

The Corliss Steel Co. is organized for the purpose of manufacturing automobiles, engines, tractors, farm machinery, machine tools, and to make and deal in forged, stamped and pressed steel and metal products. While definite plans are withheld for the present, it is reported on good authority that the new concern will begin business in the big engineering works of the defunct Wisconsin Engine Co. at Corliss, Racine County.

—

Goby in Motor Engineering Co.

CLEVELAND, OHIO, Nov. 22—The Motor Engineering Co., West Third Street, Cleveland, Ohio, has been incorporated with a capital of $30,000 by C. S. Goby, formerly chief engineer of the Goby Engine Co., and others. The company will manufacture motors and automobile parts; conduct experimental work, such as designing and general engineering work pertaining to automobiles. The new factory building now in process of construction will be occupied by the new organization about Jan. 1.

—

Gorey Buys Herreshoff Parts

NEW YORK CITY, Nov. 22—J. C. Gorey & Co., this city, has purchased from the American & British Mfg. Co., Bridgeport, Conn., all the remaining parts, jigs, tools, dies and patterns of the Herreshoff car and can now supply any material for these cars.

Last year the company purchased from the Timken Detroit Axle Co. all the remaining rear and front axles, together with the remaining parts of the Herreshoff car.

—

Dimmer Ordinance for Wilmington

WILMINGTON, DEL., Nov. 22—A dimmer ordinance has been passed for Wilmington by the Street and Sewer Commissioners, who have control of the

streets, and it will become effective Dec. 10. It is similar to the Baltimore law, the requirements being as follows:

All automobile lights in the city at night must be dimmed to at least 30 candle-power for headlights and 4 candle-power for side lights, under penalty of from $1 to $5 for the first offense and $25 for each offense after the first.

The owner of a car is held responsible unless he can supply the police with information to prove that some other person is responsible.

The ordinary "dimmer" or auxiliary lights operated by a switch from the seat will not be permitted unless the headlight itself so operated is itself so shaded or constructed that even when cut in from the seat it will not produce glare.

Gas and electric lights are permitted where they do not exceed 4 candle-power.

The use of any headlight of not over 30 candle-power will be permitted where the glass is covered with tissue paper, paint, frosting or any other substance of sufficient capacity to prevent the outline of the flame being made out.

The requirements do not apply to non-residents who are complying with the laws of their own States, unless they are asked by the police to shut off or dim their lights, which they must do.

—

After Short-Measure Gasoline Dealers

COLUMBUS, OHIO, Nov. 21—Thomas L. Calvert, chief of the dairy and food division of the Ohio Agricultural Commission, who also looks after weights and measures, is going after garages which give short measure in the sale of gasoline. A number of inspectors have started out in response to complaints from numerous automobile owners that small garages and store proprietors are giving short measure in their measuring apparatus. The law provides for a fine of $500 and six months in jail, upon conviction.

—

New Traffic Rules for Ohio

COLUMBUS, OHIO, Nov. 20—Under the provisions of the new Cass highway law, State Highway Commissioner Clinton Cown has prepared a set of traffic rules and regulations to be effective on and after Dec. 5. Some of the rules must be obeyed under penalty of the law while others are merely suggestions, one of the latter being to the effect that all vehicles, whether horse-drawn or motor-driven, be equipped with lights at night. Some of the points forbidden by the new regulations are: Unnecessary emission of dense smoke from motors; riding on any vehicle without consent of the driver; and permitting horses or domestic animals to run loose on the highways.

—

Bijur Strike Off in September

HOBOKEN, N. J., Nov. 23—The article in THE AUTOMOBILE for Nov. 18 stating that the Bijur machinists had returned to work was an error as there was not a strike. There was a strike during the latter part of August which was declared off around Sept. 13 without the company giving in to the strikers.

Territories Buying More Cars

—

Exports to Hawaii, Porto Rico, Philippines and Alaska Show Increase

WASHINGTON, D. C., Nov. 21—Figures have been compiled by the Department of Commerce showing the commerce of the United States with its noncontiguous territories during September and the nine months ended September, together with figures for the corresponding periods of last year.

Eighteen automobiles valued at $20,879 were shipped to Alaska during September, as against three cars, valued at $5,100 shipped in September a year ago. During the nine months' period the shipments increased from fifty-four cars, valued at $69,703, in 1914, to seventy-three cars, valued at $97,926, in 1915.

Shipments of cars to Hawaii show a healthy growth. During September a year ago the number was seventy and the value $75,976, increasing to 169 cars, valued at $180,083, in September last, while during the nine months' period the number increased from 616 cars, valued at $649,282, in 1914, to 857 cars, valued at $926,994, in 1915.

Automobiles to the number of thirty-four, valued at $33,542, were shipped to Porto Rico in September a year ago, while during September last the number was 103 and the value $83,052. During the nine months' period these shipments increased from 248 cars, valued at $235,357, in 1914, to 529 cars, valued at $421,815, in 1915.

There were eighty-four cars, valued at $168,491 shipped to the Philippine Islands in September last, as against four cars, valued at $4,240, shipped there in September a year ago. During the nine months' period these shipments rose from 355 cars, valued at $360,751, in 1914, to 573 cars, valued at $681,712, in 1915.

—

French Automobile Men Not Captured—Where They Are

PARIS, Oct. 23—German newspapers have informed their readers that M. Delaunay, of the Delaunay-Belleville Automobile Co., has been captured while serving as an aeroplane pilot in the French army, and also that Georges Sizaire, Albert Guyot and Arthur Duray have been made prisoners while driving automobiles at the front.

Fortunately there are a few errors in the report. No person of the name of Delaunay is attached to the Delaunay-Belleville company, the proprietors of that concern being Robert and Pierre Delaunay-Belleville, both of whom are attached to their factory, in the suburbs of Paris, and engaged on the construction of war material. The report seems to have as its foundation the capture, early this year, of a young aeroplane pilot named Delaunay, who has no connection whatever with the Delaunay-Belleville family. Delaunay was a competition driver before the war and won the last Tour de France on a Pierron car. After serving as an automobile driver at the front, he was transferred to the Flying Corps, and on his first outing lost his way and came down in the enemy's lines.

Guyot in Argonne

Since the German report appeared, Georges Sizaire has taken President Poincare on two trips to the front, and at the present moment is in Paris, attached to the President's reserve staff. Albert Guyot is attached to the headquarters staff of one of the armies operating in the Argonne, and has only been away from the front six days in fifteen months. Guyot, who is a certified aviator, having been the first man to fly in Russia, has applied for a transfer to the Flying Corps, and expects to be moved shortly.

Duray on Special Work

Arthur Duray, runner-up in the 1914 Indianapolis race, is attached to what is known as the General Automobile Reserve, and is driving a Delaunay-Belleville car. Duray, who volunteered for service, was attached to Minister Viviani for several months, and is now undertaking special missions from Paris to the front. Boillot has been made sub-lieutenant and is learning to be an aeroplane pilot. Goux is driving the military governor of Belfort. Jean Chassagne, the Sunbeam expert, has been taken out of the artillery, where he was serving as a sub-officer, and is now attached to an important aerodrome in the suburbs of Paris. He is in charge of a team of mechanics fitting Sunbeam twelve-cylinder motors to French aeroplanes. Victor Rigal, who has been both a Sunbeam and Peugeot driver, and has performed in America, is now a sub-lieutenant in charge of an automobile convoy.

Among the old-time automobile drivers Victor Hemery is a driving instructor; Louis Wagner, of Vanderbilt fame, is serving in the artillery; Rougier is an aviator; Henry Fournier has charge of a shell-making factory; Maurice Sizaire, of the Sizaire-Berwick Co., is in command of an automobile repair shop at the front; Caillois is doing similar work at Chalons; Charles Faroux, automobile editor, is attached to the government aeroplane motor laboratory and tests all new motors before they are accepted by the army; René Thomas is making aeroplane motor parts in his own shop, near Paris.

Gasoline Prices Are Higher

1-Cent Advances Reported Throughout Country—Miller Rubber Co. Elect Officers

NEW YORK CITY, Nov. 23—The rise in the price of gasoline in this city yesterday to 19 cents a gallon, has followed similar ones in the large cities throughout the country. The 1 cent rise in New York results in a corresponding advance in the retail price to 21 cents a gallon.

In other eastern cities, such as Boston, Newark and Buffalo, prices have received 1-cent advances, tank wagon basis.

In the West, including such cities as Chicago, St. Louis, Denver and points in Texas, gasoline yesterday was quoting at 1 to 2 cents higher. In Texas, the present price is 19 cents a gallon, an advance of 2 cents. For the fifth time in about two months the price of gasoline has gone up 1 cent in St. Louis, quoting at the filling stations at 15 cents. The price will be duplicated by the independent companies. Gasoline prices have been advanced 1 cent a gallon, tank wagon basis throughout Wyoming, Montana and Colorado by leading distributors. Denver prices are now 18 cents a gallon, tank wagon basis. The price to consumers is 19 cents. This is the sixth advance in the retail price within sixty days. Chicago prices have been advanced 1 cent to 14.102 cents a gallon, flat, tank wagon basis.

A further tightening of gasoline prices in the Milwaukee district is indicated by the announcement issued on Nov. 19 by the independent jobbers to the effect that the quotation on tank wagon delivery in lots of 100 gal. or more has been withdrawn, and in the future the quotation will be on the existing tank wagon delivery basis, any quantity. The 100-gal. quotation has been uniformly 1 cent under the ordinary tank wagon price, which is about 1 cent lower than the filling station quotation. The announcement, in effect, means a 1-cent increase in tank wagon prices for large lots. Only two sets of quotations will be issued until further notice, as follows:

Sp. Gr.	Filling Station (cents)	Tank Wagon Delivery (cents)
59°	14.5	13.6
62°	16.0	15.0
65°	19.0	18.0
70°	22.0	21.0

Miller Rubber Officers Re-elected

AKRON, OHIO, Nov. 20—At the annual stockholders' meeting of the Miller Rubber Co., recently held here, all the officers and directors were re-elected. This includes Jacob Pfeiffer, president, C. T. Grant, vice-president; F. B. Theiss, treasurer and assistant secretary; W. F. Pfeiffer, secretary and assistant treasurer. They, together with J. M. Doran, comprise the board of directors.

The president's report showed an increase in surplus to $813,000, and common dividends were increased from 10 to 12 per cent per annum, as reported in THE AUTOMOBILE for Nov. 18. Sales for the year were 30 per cent greater than the year previous. The company also increased its floorspace during the year by 6½ acres.

Markets Continue Rise

NEW YORK CITY, Nov. 23—Market prices soared last week. With the exception of tin which dropped $3.75 per 100 lb., prices were extraordinarily high. Crude oil from Pennsylvania is now selling at $2 a barrel and Kansas crude is quoted at $1. Both electrolytic and Lake copper reached new high marks when the market closed last night. Eectrolytic, after an advance of ¼ cent, closed at 20 cents a pound. There is an enormous domestic demand with large buying for future delivery. Foreign orders for copper have not shown any signs of slackening.

Crude rubber prices reached new high marks. Up-River Para yesterday sold at 75 cents a pound. First latex pale crepe rubber from Ceylon rose to 88 cents. For several weeks the quotations for both Para and Ceylon grades have been advancing, but at no time has there been such a big jump as between last Saturday and yesterday. Higher prices are looked for. The recent closing of the Suez canal by the English government had a potent effect on the quotations. Authorities state, however, that this is not the only reason for the high prices. The stocks of plantation rubber actually in the London market are not very large. According to a recent cable, there were 3200 tons lying outside that had not been unloaded. The closing of the canal will mean that it will take three weeks to a month more to lay down plantation rubber in London than formerly. The amount of Para rubber on hand in Brazil is said to be only moderate.

Bill for More Severe Punishment in Bay State

BOSTON, MASS., Nov. 20—A bill has been filed in Massachusetts to make the penalties more severe for motorists. If a motorist goes away after an accident the penalty is to be a fine of not less than $100 nor more than $1,000, and imprisonment for not less than three months nor more than three years, or both a fine and imprisonment.

In case death results and the driver is apprehended after fleeing the penalty is to be not less than ten years nor more than twenty years. Also it makes it prima facie evidence of willful neglect and criminal intent, and in a suit for damages if the injured person wins the judge shall order that whatever sum is awarded by the jury shall be tripled.

Where convictions occur on charges of operating while under the influence of liquor the clerks of the courts are ordered to notify the Highway Commission within 24 hr. That body is then to suspend the license indefinitely. A second conviction on the same charge calls for the permanent revocation.

New Paterson Distributor in Phila.

PHILADELPHIA, PA., Nov. 19—The Paterson Motor Sales Co., this city, has been formed by C. O. R. Kindig and D. M. Martin, formerly with the Maxwell Motor Co., with temporary offices at Broad and Race Streets. The company has been incorporated and Mr. Kindig is president. Mr. Martin, who is vice-president and treasurer, will concentrate on the wholesale end.

Stewart-Warner Salesmen Meet

CHICAGO, ILL., Nov. 22—The sales force of the Stewart-Warner Speedometer Corp. concluded a five-day meeting here yesterday in which three days were given to factory inspection and two days to a convention at the Hotel Sher-

man. Thirty-eight representatives from all parts of the country were in attendance. During the three days at the factory they were given practical demonstrations of the mechanical features of the company's product and at the two-days' convention, that which they had seen demonstrated at the factory was further explained by means of charts and diagrams. Luncheon was served on the last day.

—

White Not to Exhibit

NEW YORK CITY, Nov. 22—The White Co., Cleveland, Ohio, has decided not to exhibit at either the New York or Chicago show. It is understood that one cause of the company deciding not to exhibit was that at the recent drawing for space, a new rule was put into force by which the order of drawing was in proportion to the amount of passenger car business done during the previous year, whereas formerly the order of drawing was determined by the total volume of business of passenger cars and trucks. White is one of the largest producers of trucks and voting this part of their business out of the reckoning naturally placed them further back in the list of drawing.

—

Ames Co. Handles Packard and Dodge

OWENSBORO, KY., Nov. 20—The Ames Motor Car Co., this city, has secured the agency for the Packard and the Dodge.

—

Ford Parts Sold in 10-Cent Store

PHILADELPHIA, PA., Nov. 20—Parts for Fords are being sold in a 10-cent store in this city. A counter is being devoted exclusively to the sale of parts for Ford cars at 10 cents each.

Securities Continue to Rise

—

Paige 110-Point Rise and Ajax-Grieb 50-Point Feature Market

NEW YORK CITY, Nov. 23—Automobile and tire issues continued their upward movement in prices last week, some of the stocks reaching new record marks. General Motors gained 27 points and reached the high mark of 419; Goodyear closed at 338 with a gain of 10 points; Paige-Detroit made a record mark of 660 or 110 points higher, the stock last week showing an 85-point rise, and Ajax-Grieb, which closed on Saturday at 350, developed a 50-point rise.

A number of the stocks rose to high points during the week and then dropped, among these being Willys-Overland, which rose to 245 on Wednesday and then dropped to 228 on Saturday, and Studebaker, which rose to 167½ on Wednesday and then dropped to 151 on Saturday.

Saxon Stock Sells Well

The subscriptions for stock of the Saxon Motor Co. are coming in very heavily and it is expected that the stock will be oversubscribed.

Several issues dropped, notably Portage Rubber common, which went down 15 points, and Kelly-Springfield second preferred, which dropped 18 points. Peerless common went down 5½ points and Chalmers common dropped 5 points. Willys-Overland common closed with a 19-point loss.

There were a few small gains such as 5 points for Reo Car; 6 and 2 points for Stewart-Warner common and preferred; and 2 points for General Motors preferred.

—

Auto Wheel Co. Adds Again

LANSING, MICH., Nov. 17—For the third time since March 1, an addition to the plant of the Auto Wheel Co., is to be built. It will take the place of a wooden building and will occupy all the vacant land on the west side of the plant. Ten new dry kilns will be installed, bringing up the total the company will have to twenty-seven. At least fifty more workingmen will be given employment by Jan. 1. The additions and new equipment put in by the company this year represent an expenditure totalling to $75,000.

—

Studebaker Service Building Finished

NEW YORK CITY, Nov. 22—The Studebaker storage and service building in Long Island City has been completed and will be occupied this week. It is a concrete structure 80 by 160 on the western side of Anable Avenue, south of Meadow Street.

Owner Convicted of Manslaughter in New York

NEW YORK CITY, Nov. 18—The first conviction for manslaughter resulting from an automobile accident that ever has been found in Queens County was returned yesterday by a jury in the case of M. H. Conroy, who ran over a Long Island Railroad flagman. The conviction was liable to carry a 15-year sentence, but Judge Humphreys inflicted a penalty of only three months imprisonment.

Mail Trucks in St. Louis

ST. LOUIS, MO., Nov. 15—The St. Louis mail service to-day was motorized. Fifty new government owned motor trucks replaced the wagons, street cars, leased automobiles, bicycles and whatnots which heretofore had been used in collecting and delivering mail in this city and its suburbs.

Twenty of the trucks were delivered to the government by the General Motors Truck Co. of this city at a cost of about $30,000. Fourteen are of 1500-lb. capacity and six of 3000 lb.

Curbstone Dealers Need No License

LANSING, MICH., Nov. 18—According to an opinion given by Attorney-General Grant Follows, to Secretary of State Coleman C. Vaughan, automobile dealers or agents who sell cars but have no garage or do not operate a garage, and who are generally spoken about as curbstone dealers, do not have to take out a dealer's license. They must, however, register each machine they control and operate or get a general license number for them as provided by the law.

The opinion was brought about in reply to the following letter from the Secretary of State: "We have several parties in this place that are running a curbstone agency, that is, they have the agency for different makes of cars and are selling same but still do not run a garage. Can you tell us if these parties are supposed to have a dealer's license and pay a license of $50 like other parties who own garages, or are they exempt? We feel that if they are selling cars they should have a dealer's license and we would be pleased to have you advise us on the matter."

Cooper in Stutz Wins Ariz. Grand Prize

PHOENIX, ARIZ., Nov. 20—*Special Telegram*—Earl Cooper added another victory to the Stutz string to-day when he was awarded first honors in the Arizona Grand Prize, the closing feature of the annual State Fair. The race, scheduled for 150 miles was called at 5.25 p. m. because of darkness and dust. At that time Cooper was leading. He had covered 109 miles in 1 hr. 42 min. and 30 sec., an average of 63.8 m.p.h.

When the race was called Parsons, also at the wheel of a Stutz, was second, having completed 108 miles in 1:42, while Walterman, driving an Overland, was third, his time for 103 miles was 1 hr. 42 min. 31 sec. Out of a field of thirteen starters the following cars were still in the race when flagged:

Sebring, Haibe, 102 miles; Apperson, Price, 100 miles; Durant Special, Durant, 97 miles; Duesenberg, Bolden, 93 miles; Stutz, Wood, 93 miles; and National, Reeves, 86 miles.

Barney Oldfield's Fiat went out with a broken connecting-rod before it had covered a mile.

90 Per Cent Rebate to St. Louis Exhibitors

ST. LOUIS, MO., Nov. 19—A rebate of 90 per cent to exhibitors at the last annual automobile show held by the St. Louis Manufacturers' and Dealers' Association has been declared. Joseph A. Schlecht, chairman of the show committee, said that the earnings of the show would warrant even a 92.8 per cent rebate, but it was considered advisable to divert 2.8 per cent of the earnings into the treasury of the association.

This is the largest rebate ever paid in the history of the organization. The largest previous rebate was 60 per cent, paid to member exhibitors at the 1913 and 1914 shows. Exhibitors at the 1915 show who were not members of the association will not share in the rebate.

Rules for Amateur Race

Drivers Must Own Cars Which Must Be 1914 Models or Newer

CHICAGO, ILL., Nov. 22—The contest board of the Chicago Automobile Club has accepted a set of rules, drafted by a special committee, under which the amateur drivers' race, tentatively scheduled for the Chicago speedway in May, probably will be run.

The rules, which have been sent to the A. A. A. contest board for ratification, stipulate that only amateurs may participate in the proposed event and that each entrant must own the car. The nomination of any car antedating a 1914 model will be refused.

Each car must carry complete equipment as listed in the catalog of the maker, with the following exceptions—spare tires and wheels, tool box and jack. Lamps and windshields may be removed at the track on the day of the race but tops must be carried.

In order to qualify, each driver must make one lap of the 2-mile track at an average of 55 m.p.h. or better. After the time trials, the cars will be divided into three equal divisions and three elimination heats, each of 20 miles, run. The first four cars to finish in each heat will be eligible to compete in the finals, which will be a 50-mile contest.

Although the date of the proposed race is more than five months away, twelve entries already have been promised. They include four Mercers, three Stutzes, two Nationals, two Cadillacs and a Stearns-Knight.

Motor Mail Service for Chicago

CHICAGO, ILL., Nov. 19—Beginning Nov. 21, seventy-six White trucks will supplant the street car service between the main postoffice and the outlying substations. When circumstances permit all horse-drawn vehicles in the postal service of Chicago will be superseded by motor vehicles. The cars are to be owned and operated directly by the federal government, whereas the team and street car service which they will replace was under contract by private owners.

Speedwell Receiver Finishes Work

DAYTON, OHIO, Nov. 18—C. R. Green, receiver for the Speedwell Motor Car Co., in the action of the Dayton Savings & Trust Co. for foreclosure on mortgage bonds, has filed his final account and been discharged as receiver. His report shows $19,180.20 received and expended as receiver between Aug. 4 and Nov. 4, 1915.

Howe Rubber Adds—The Howe Rubber Co., New Brunswick, N. J., maker of automobile tubes, will expend $70,000 for the construction of a new factory building in that city.

Equipment Co. to Build—The Champion Auto Equipment Co., Chicago, Ill., has purchased a plant at Wabash, Ind., where it will manufacture automobile tires, tire inflators and pumps.

To Make Parts in Boonton—The Central Machine & Supply Co., New York City, has acquired a site at Boonton, N. J., where it plans to establish a plant for the manufacture of automobile parts.

To Make Tires—A tire plant is planned for Wichita, Kan., by the Wichita Auto Tire Manufacturing Co. with a capital of $600,000. The incorporators are Charles Darrigrand, Ransom Stephens, C. H. Matson, W. T. Watson and M. V. Price.

National Rubber Adds—The National Rubber Co., Pottstown, Pa., is having a two-story reinforced concrete factory and a one-story power house built at Pottstown. The former is 135 by 170 ft. and the latter 45 by 120 ft.

To Make Spring Wheels—The Montana Improved Wheel Co., recently incorporated, contemplates the construction of a plant at Bozeman, Mont., for the manufacture of a spring wheel for automobiles.

Savage Tire Adds—The Savage Tire Co., San Diego, Cal., will build an addition to its plant on Main Street.

Oregon Co. to Build—The Oregon Motor Car Co., Portland, Ore., is preparing to build a plant 100 by 100 ft., costing $30,000.

Double-Tread Tire Plant in Salt Lake City—A. C. Friedman and Frank Sale, president and vice-president of the Western Double Tread Tire Co., 1241 Broadway, Denver, and Leo Jacobson, are organizing a Utah corporation to operate a double-tread tire plant in Salt Lake City.

To Make Steel Wheels—A new firm to be incorporated as the Ideal Wheel Co. will be established in Massillon, Ohio, for the manufacture of steel wheels for automobiles. Arnold Markel, Cincinnati, will be general manager. It will occupy a building at the plant of the Everhard company.

Limousine Top Buys Bldg.—The Limousine Top Co., Kalamazoo, Mich., has purchased a two-story building, 50 by 200 ft. which was part of the old Michigan Buggy Co. plant. A warehouse, 40 by 80 ft., has also been acquired. The company's business required these additions to meet the big increase in sales.

A. O. Smith Adds—The A. O. Smith Co., Milwaukee, Wis., pressed steel frames, parts and motor trucks, is about to erect a new boiler house to accommodate the increased demand of its power plant. The building will be 40 by 70 ft. in size and 50 ft. high, and contain three 300 hp. boilers, together with the latest conveying, stoking and pumping equipment. The company will spend $35,000 in the improvement.

Gemmer to Increase Production.—The Gemmer Mfg. Co. of Detroit, Mich., which makes steering gears, will greatly increase its production when additions to the plant, now under way, are completed. One addition consists of a two-story building, the size of which is partly 171 by 60 ft. and partly 138 by 60 ft. An alley, 20 by 350 ft., has been closed to give further room. These additions will enable all departments, principally the assembling, service and machine departments, to be relieved of their present pressure. According to officials, the business of the company is very good and orders now on hand will keep the plant running to full capacity for the next six months. The outlook is the brightest the company ever had.

The Automobile Calendar

Nov. 22-27.....Binghamton, N. Y., Show, State Armory, Binghamton Automobile Dealers' Assn.

The Week in the Industry

Battle Creek Hupp Moves—W. E. Teeter, Battle Creek, Mich., Hupmobile agent, has removed from 27½ West Jackson Street to 14 West Jackson Street.

Philadelphia Body Co. Adds.—Contracts have been awarded for the erection of two warehouse buildings 55 by 270 ft. and 64 by 90 ft., respectively, at Nineteenth Street and Glenwood Avenue, Philadelphia, for the Hale & Kilburn Manufacturing Co., makers of automobile bodies.

Philadelphia Metz Makes Lease—The Metz Automobile Co., 338-340 North Broad Street, Philadelphia, has leased property at 3437 North Broad Street, which has been converted into a showroom and service station, for the accommodation of the new Metz commercial car.

Recent Changes in Seattle—The McQuay-Norris Manufacturing Co., St. Louis, maker of Leak-Proof piston rings and Lynite pistons, has established a factory office in Seattle to look after the firm's interests in the Pacific Northwest. E. G. Norris, brother of President W. K. Norris of the St. Louis factory, is in charge of the office there.

The Willard Storage Battery Co., Cleveland, Ohio, has opened a branch office in Seattle in the Joshua Green Building, in charge of J. P. Schiller, Jr.

Recent St. Louis Changes—The Megue Rubber Co., St. Louis, has been appointed distributer of Mohawk tires in eastern Missouri and southern Illinois. Twenty-four subdealers have been established in St. Louis and ten in surrounding towns.

The Johnson Automobile Co., 3667 Olive Street, has been appointed distributer of H. & D. shock absorbers in Missouri and southern Illinois. Clermont Rider, formerly distributer in the St. Louis territory of H. & D. shock absorbers, has been appointed sales manager of the company and hereafter will be stationed at Goodland, Ind.

The Vehicle Top & Supply Co. has been appointed distributer in Missouri and southern Illinois of the Murphy disappearing truck body. The body is especially adapted to Ford roadsters and takes the place of the tool box.

A. H. Sullivan & Co., St. Louis, has been appointed distributer of the Form-a-Truck in the St. Louis district. This is an extension attached to the chassis of Ford cars lengthening the wheel base to 125 in. and increasing the capacity to 1 ton.

Motor Men in New Roles

Wert Marion Supervisor—G. E. Wert has been made supervising distributer of Marion cars in practically one-half the State of Ohio and southern Michigan.

Nickolous Changes—H. J. Nickolous, formerly with the Studebaker Corp., has been made secretary of the Newell Motor Car Co., Hayes distributer in eastern Missouri and southern Illinois.

Jeffery Hupp Manager—C. E. Jeffery, Jr., formerly of the Wheelock-Jeffery Co., agent for the Oldsmobile at Boston, Mass., has been appointed manager of the Hupmobile Co., New England.

Reed Hollier Rep.—G. G. Reed, until recently New England distributor for the Detroiter, has become New England traveling representative for the Hollier Motor Sales Co., covering Maine, New Hampshire and Vermont.

Cramer Joins Carr—V. C. Cramer has been appointed manager of the Detroit branch of the F. S. Carr Co., Boston, which makes material for automobile tops. Mr. Cramer was formerly president of the American Distributing Co., Detroit.

Toebe Heads Hupmobile Station—The Harrington-Roebe Auto Repair Co., 717 North Grand Avenue, St. Louis, has been designated an official Hupmobile service station. The garage will be open day and night and will carry a complete line of Hupmobile parts. J. C. Toebe, formerly with the Weber Implement & Auto Co., is in charge.

Alfred Resigns—J. N. Alfred, who has been cashier of the Wilson Foundry & Machine Co., Pontiac, Mich., has resigned to become auditor of disbursements of the Timken-Detroit Axle Co., Detroit. Mr. Alfred was for over two years in charge of the credit and collection department of the Oakland Motor Car Co.

Dealers

Times Square Opens New Branch—The Times Square Auto Co., New York City and Chicago, has opened a branch at Kansas City, Mo.

Pittsburgh Packard Builds—A service station, three stories high, 100 by 224 ft., will be erected at Pittsburgh for the Packard Motor Co.

New York City Leases—The Hudson Motor Car Co., New York City, has purchased a site, 100 by 100½, on the north side of West Sixty-seventh Street, 125 ft. east of West End Avenue, and will erect a six-story automobile building to cost $150,000. The site cost $55,000.

The Nordyke & Marmon Co. has leased a site, 60 by 100, at 42-44 West Sixty-second Street, and will erect a five-story sales and service building. The present building was first occupied as a car establishment in 1903, by the White Co.

The Goodyear Tire & Rubber Co. has leased a store at 10 Central Park West, together with a basement space and offices on the second floor.

St. Louis Westcott Moves—The Westcott Motor Sales Co., St. Louis, has closed a lease for the garage of the former Cherokee Automobile Co., 3334 South Jefferson Avenue. This building with 8000 sq. ft. of space, will be used as a service station for Westcott owners and for general repair work.

Madison Dealer Builds—Rademacher & Jaeger, Milwaukee, Wis., Paterson distributers, are building a salesroom, 66 by 100 ft. and two stories, at 2805 and 2807 Vliet Street. The company has closed a contract with the Paterson Co. for 100 6-42 light sixes.

New Willard Service Stations—The Willard Storage Battery Co., Cleveland, has added the following service stations, making a total of 565: Keokuk Armature Works, 1001 Johnson Street, Keokuk, Iowa; A. P. Louch, 32 King Street, Brockville, Ont.; Bond Electric Co., Inc., 186 Main Street, Hornell, N. Y.; T. Carlson Electric Co., Brownwood, Tex.; Macan Jr. Co., 129 Ferry Street, Easton, Pa.; Fairbanks Electric Co., 58 North Main Street, Norwalk, Conn.; Beebe Electric Co., Bedford, Iowa; J. H. Spinharney, Cherokee, Iowa; Norfolk Tire Repair Co., Fourth and Braasch Streets, Norfolk, Neb.; Danville Storage Battery Co., 326 Craghead Street, Danville, Va.; Anaheim Ignition Depot, Anaheim, Cal., and Central California Electric Co., Elmwood Avenue, Lindsay, Cal.

Overland Building in Boston—The Overland Stores Co. is the name of the company that has taken title to a tract of land in the Back Bay section at Boston, Mass., upon which will be erected a four-story structure for the Connell & McKone Co., New England, distributor of Overland cars. The land has a frontage of 215 ft. on Brookline Avenue, and 495 ft. on an adjoining street. The Willys-Overland Co. is erecting another big place at Springfield and others will be put up elsewhere.

VOL. XXXIII NEW YORK—THURSDAY, DECEMBER 2, 1915—CHICAGO No. 23

The AUTOMOBILE

Lighting Systems Simplified

Standard Lighting and Starting Equipment for 1916 Is Lighter, Simpler, Neater and More Efficient —Better Wiring—Oiling Only Attention Needed

By A. Ludlow Clayden

LIGHTING and starting systems, of which there are many makes, divide naturally into main divisions. First come those which hold between them the great bulk of the car manufacturers' business; second, are many more which share with some of the former the growing trade in equipments for Ford cars and old vehicles which were sold originally without any electric equipment. In the following the first class will be considered, though the general remarks apply to both fields to a very great extent. The second class of instrument is frequently as interesting from the viewpoint of its method for attachment as from that of its electric system, and this class will be considered in a later review.

Still Enormous Variety

Being the newest portion of the automobile chassis it is natural that the lighting and starting system should be the furthest from a settled form. Both electrically and mechanically there are still many systems of construction, there is little agreement between one manufacturer and another, and it is difficult to trace any definite trends except in a very broad way.

One definite thing which is more distinctly traceable this year than it was last, is the growth in popularity of the two-unit system. There are a few notable exceptions, but it is the opinion of the majority of manufacturers of generators and starting motors that the two-unit for large cars is a settled type. For small cars, cars of which the engines are sufficiently small not to need much electric power for starting, the single unit is cheaper and is giving satisfactory service.

Another striking point is the gradual elimination of "controls." At one time it was a common idea that some regulation was necessary so that the difference between summer and winter conditions could be met. For instance there are some systems which allow the generator to be set to cut in and start charging at a lower engine speed for winter work. Now only quite a few of these remain, since it is found that a system which will give all the current needed for winter driving will not overproduce to a harmful extent in the summer.

Next in order of development may be put a general mechanical simplification, which brings in its train some reduction in weight.

Starting Motor Drives Simplified

There are hardly so many methods in use for connecting the starting motor of a two-unit system to the engine. Practically the Bendix pinion reigns supreme in every instance where the toothed flywheel is employed and there is no additional gear reduction between the crankshaft and the armature shaft of the motor. The success of the Bendix pinion is a remarkable instance of what can be accomplished by a timely invention; certain small drawbacks found with the first installations have been overcome, and at present the magnetic and other forms of pinion shift find extremely little favor, though they have each special points of advantage.

Too Many Patterns

There is still a ridiculous number of shapes and sizes and patterns for generators and starting motors, not because of the numerous makes, but on account of the multifarious patterns made by each manufacturer, in the majority of instances. Time will cure this, of course, since the present state of affairs is uneconomical, bad for the electrical firm, bad for the automobile manufacturer, bad for the user and terrible for the repair shop men. It makes for inefficiency all along the line.

The cause for the state of affairs is twofold. First, the electrical specialists had to make many large scale experiments, and it is only lately that the two or three best electrical constructions have been decided upon. Secondly, automobile manufacturers called for generators and motors of such and such dimensions to suit their engines and their chassis, and the electrical manufacturers did not hesitate to produce a "special model" to meet the detail requirements of each car builder.

The worst of this chaos is over and another couple of years will see the situation in a properly standardized condition, probably with the help of the S. A. E. which will be forthcoming as soon as everyone agrees that the time is ripe.

From the user's viewpoint the weak parts of the electrical equipment are the wiring and the battery. For the latter the user is himself altogether responsible. If the battery is not kept full, and if the hydrometer is not used regularly, trouble is certain. It takes longer to kill a battery by refusing it water than it does to kill an engine by withholding oil, but ultimate death is equally sure in either case.

For the wiring the automobile manufacturer has to take the blame. It is infinitely better than it was a year ago. Wires in armored casings are the rule and wires are generally shorter than of yore. Clearly marked connecting terminals, easily accessible fuses, different colored wires and such aids to upkeep are found on most cars, but it is still possible to see room for improvement. It is becoming recognized that the proper place for all junctions and connections is on the dashboard or the cowl board, preferably the latter, and that all switches and other controls should be brought close together. It is easy to trace a long wire to a lamp or to the battery, but there is danger in a maze of cross connections from switches to fuses, fuses to junction boxes and so on.

However, considering the limited time in which the whole electrical part of the gasoline automobile has been developed the state of comparative perfection reached is very remarkable indeed. It reflects the greatest credit upon the electrical manufacturer, and upon the automobile maker. Apart from the battery and the wiring the next weak spot seems to be the tendency of users either to swamp the generator with oil or not to oil it at all. An armature spindle of a generator needs a little oil, but only a little, and usually it needs that little fairly frequently. Two or three drops is enough for a dose, but a big supply at infrequent intervals is *not* by any means equivalent to a proper oiling at proper intervals.

Next in rules for owners should be "suspect the generator last of all."

First make sure of the state of the battery.

Second, make sure of the tightness of all wire connections.

Third, test for broken wire.

Fourth, see that the switches are operating properly and are not broken or loose.

Fifth (only after the first four are made sure), see if the cut-out is misbehaving, and then—

Sixth and last, there may be something the matter with the generator, though the chances still will be that something has been overlooked in the first four examinations.

All a generator or starting motor needs is to have the commutator cleaned once in a while and the brushes reset or renewed, but this last is not a job for any man who is totally ignorant of electrical machines.

Electric Systems Simpler

The main reason for the reliability of the modern generators and motors is their increased simplicity and much better protection against dirt and moisture. The modern system of insulating by impregnation under heavy pressure and considerable heat has almost made impossible any internal leaks in armature or other windings, and materials have now been found to support the arduous conditions of service of the brushes. Commutator construction has also been improved, this being a purely mechanical problem. On the electrical side, the methods for regulating the current are, on the whole, simpler and more effective. For one thing, such an enormous amount of data is now available that it is easy to determine the output which is necessary for a car of given size. Then, too, the special points of one or another system have been discovered to have specific applications of especial merit; electrical manufacturers have found out how best to meet required conditions of weight, size, cost, etc.

As an example of the sort of problem which has been brought to a less unsettled state, it is found that the current required for lighting a small car is almost as great as for the largest vehicle, while the current needed for cranking is much greater with the larger engine. Thus to make a single unit generator and starting motor is much easier for small cars as the motor part can be small, the generator part needing to be practically of the same power as that required by a large car.

The main systems of regulating the output of generators

so as to produce enough, but not too much electrical energy under all the various conditions of speed and loading, were dealt with in THE AUTOMOBILE on Oct. 21, 1915, so there is no object in going over the ground again, as there are no new principles.

The 1916 designs show that the vibrator system for controlling either voltage or current has increased greatly in popularity. Meanwhile the third brush system is likewise popular and there are many machines that utilize the reversed series system, the simplest of all if not the most efficient perhaps.

Bucking coil regulation is less frequently encountered, but it is used for some machines of the highest possible quality.

It seems that we are still a very long way indeed from agreement as to which is the best system of all.

The Westinghouse System

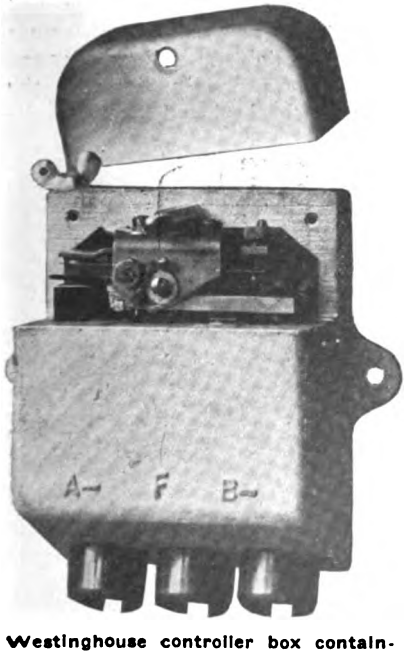
As might be expected the Westinghouse Co., holding such an important position in the electrical world, has not let any grass grow beneath its feet, and as a result Westinghouse lighting and starting systems are to be found on very many cars to-day.

Making a variety of patterns the most popular type for 1916 is the one which uses the vibrator system of control, this machine having a practically constant voltage whether the battery be connected or not. Once start the engine and the battery becomes hardly necessary. The Westinghouse generator is usually a four-pole machine. If for current supply only, the generator is round and has all four poles wound, but if it combines the ignition coil it is rectangular with all windings contained in the upper part and the armature at the bottom. Various sizes are made to suit different cars, but the construction is similar in all.

Single unit Westinghouse systems are made for some special purposes and these operate at 12 volts, but the most usual two-unit systems are all 6 volts.

The Westinghouse company are protagonists of the single wire principle, in which the frame of the car is used as the return for each circuit, and all their machines are made for use with single wires only.

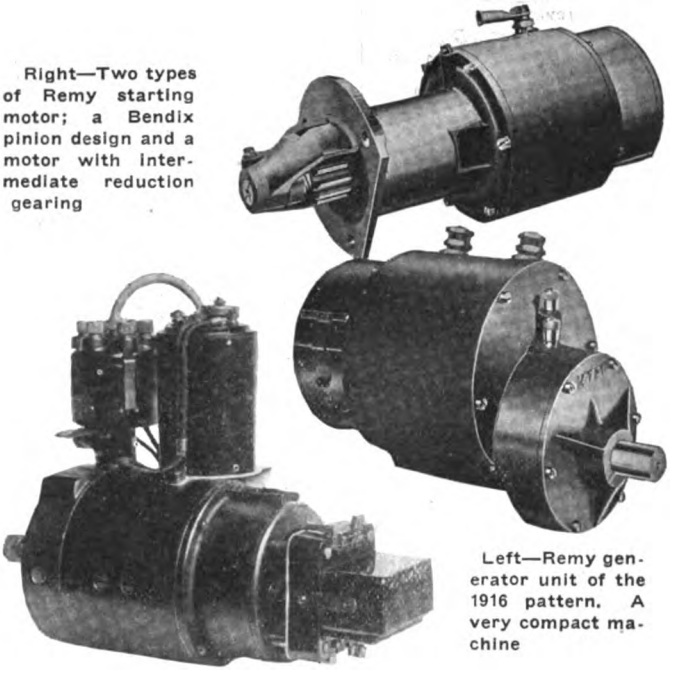
During the past year development has been almost all in mechanical matters connected with the manufacture of the machines; for instance, a much more extended use is now being made of laminations. The field magnets for the generators in many sizes are made up of stampings of sheet iron instead of from castings or forgings, this being the preferred method, both from electrical and mechanical viewpoints, but it has taken some time to lay down the necessary plant to take care of the present large output.



Westinghouse controller box containing voltage vibrator

Commutator and brushes are extra large and are designed to give several years of service without renewal.

The regulator requires no attention whatever except at very long intervals, indeed, but is provided with a voltage regulating screw which can be used by the factory in setting the machine to produce the required characteristic curve of performance.



Right—Two types of Remy starting motor; a Bendix pinion design and a motor with intermediate reduction gearing

Left—Remy generator unit of the 1916 pattern. A very compact machine

For the motor generator and for some special types of two-unit the Westinghouse Co. also make use of the inherent system of regulation and of the bucking coil system, but the vibrator is far the most popular this year. Westinghouse starting motors are supplied in several shapes and sizes for different requirements and for use with either the Bendix pinion engagement for the flywheel or a similar pinion with magnetic control.

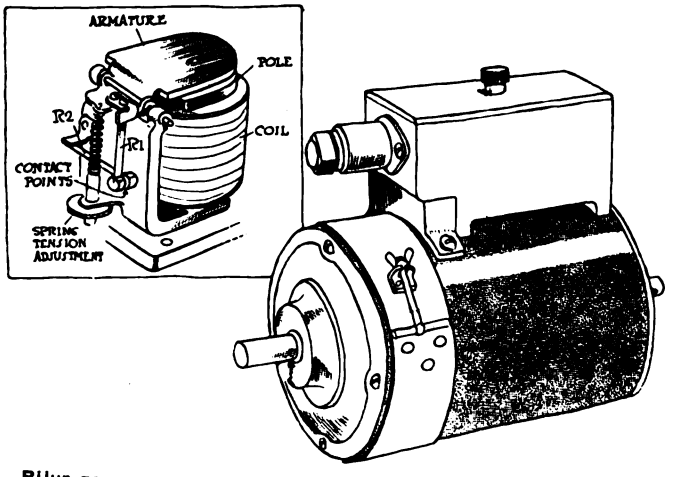
While the Bendix is the most popular the magnetic shift is being used for a few high-priced cars, owing to the fact that it needs but the depression of a button, a much heavier switch action being needed for the other. The magnetic shift motor has an armature capable of moving longitudinally and there is a simple pinion on the flywheel end. This normally overhangs the flywheel gear and has *helical* teeth as has the flywheel ring gear. At the front end of the motor is a little box containing a coil of wire through which passes all the current on its way to the motor, and there is a soft iron end piece on the armature shaft, a spring back of everything keeping the pinion normally out of mesh with the flywheel. When current is switched on, as the pinion starts to move, the current in the end coil sucks the armature forward and meshes the gears.

Now, as soon as the motor reaches a certain speed which is a trifle above cranking speed, the back current generated within the motor greatly reduces the power of the suck on the armature and the spring breaks the pinion out of mesh automatically. The helical teeth make for instant engagement and assist disengagement, since the flywheel tends to throw out the pinion. Further, if the pinion should fail to engage and start to spin the back current prevents the engagement taking place. Either the pinion slips in without a sound or nothing happens, but in practice it is very rarely indeed that engagement fails.

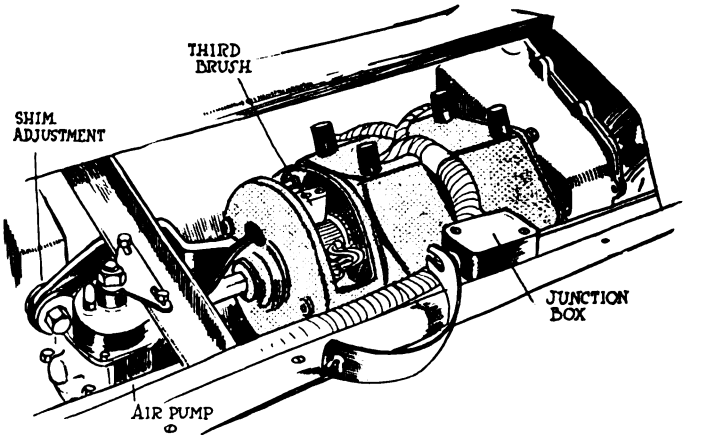
A strong feature of complete Westinghouse equipments is the robust nature of the switches and fuse boxes and other small parts.

Delco Systems Have Strong Hold

The Delco system is usually a single unit, but the name is a misnomer, for the single Delco apparatus would be described more correctly as a compound system. The main advantage of the two-unit system is that the armature of the generator can be geared to suit the crankshaft speed so that it runs



Bijur generator with voltage control mounted on it in sealed box. Also details of voltage controlling vibrator R1 and R2, being the two blades which allow the contacts to vibrate in two directions



Dyneto single unit as applied to Franklin car. It can be seen that there are three brushes and that the wiring connections are simple and accessible

normally at the most efficient rate, which is far less than the rate necessary for starting when the machine is used as a motor. With a constant ratio between armature and crankshaft the armature has to be larger than necessary for generation in order to get enough starting torque. The Delco machine has a single armature with a pinion on the rear end and a drive connection on the front end, but inside the front end there is a roller clutch so that the armature can overrun the engine. If the engine stops the armature can spin on till its own small friction brings it to rest.

Thus, when the current from the battery is turned into the armature it can spin freely without affecting the crankshaft of the engine. When in use as a generator the machine operates quite like any single unit type with inherent regulation. It is but little larger and but little heavier. To use it as a motor for cranking there is a duplex intermediate pinion which can be slid mechanically, like a transmission gear, and this engages simultaneously with the flywheel ring gear and the armature pinion. By an ingenious switch combination the action of depressing the pedal that slides the gear also operates the switch, so meshing is performed and current turned on by one movement.

The effect of using the intermediate gearing, which as the sketch shows is in itself a reduction gear, is to give the armature a very high cranking speed, and this is highly desirable from the electrical viewpoint.

Improvements in the Delco system have been progressive for years, but they have not affected the principle, nor have they altered the external appearance very much. Reliability on an increasing scale has been sought by ever better methods of manufacture.

Early in the present year the Delco two-unit system appeared, this being made to suit a particular car which was not readily adaptable to the usual single unit. This two-unit type is to be employed on more than one 1916 car, but the single machine remains the Delco standard. Probably there are few leading firms who concentrate so closely upon a single design as do the Delco and the company is to be congratulated on the fact that its original system has held its place from the very beginning of electric equipment right up to the present moment.

Remy Has New Two-Unit

The principal Remy system for 1916 will consist of a unit generator and ignition system, with a separate starting motor. The generator is regulated by a vibrator, but this is arranged so as to control the current output instead of controlling the voltage. Should the current rise above a predetermined point the magnetic action of the vibrator introduces resistance and reduces the current instantaneously, then as the vibrator lets go again the current rises, only to be cut once more as the vibrator is again pulled open. The action is extremely rapid and the fluctuating current produced has the same effect as a steady current, it is steady to all intents and purposes, the variations being infinitely more rapid than can be detected by any recording instrument. Of course, the voltage varies in just the same way with the other method for linking in the vibrator, the average being steady in just the same manner. The only difference which affects the user is that the current controller type like the Remy generator cannot be used without the battery in circuit as it is the battery which controls and restrains the voltage.

With the Remy arrangement there is a four-pole field magnet with all poles wound, and three brushes are employed.

Externally, the generator is wonderfully compact, the vibrator and the cut-out automatic switch being housed in a small box which is screwed to the generator base. The ignition distributer is mounted on the other end of the machine and the ignition coil stands on a pedestal on top of the field magnets. The system of control allows a high output from a small machine, so the new Remy is light as well as compact.

For the Remy starting motor the Bendix pinion is the standard form of coupling to the flywheel and the motor it-

Details of brush gear and external view of the control box used with the new Bosch Standard generator set

self is a substantial four-pole machine with plenty of power. The commutator and brushes have been constructed with the intention that they shall operate without needing attention during the life of the car and they are certainly of extremely generous proportions.

Gray & Davis 30 Per Cent Lighter

For 1916 the electrical system of the Gray & Davis machines has not been altered, but substantial changes in the mechanical detail have enabled the weight to be reduced by almost one-third. This reduction is mainly owing to the adoption of a four-pole machine of the roll frame type with pressed steel end caps. In addition to this commendable saving of weight the Gray & Davis reliability has been improved still more by giving great attention to the mounting of the bearings, which are each provided with a large oil container and efficient means for excluding dust or dirt.

Also the accessibility of the brushes has been improved so that by sliding off one side cover both brushes are laid bare for examination.

Both double and single unit Gray & Davis systems are made, the latter being used for small engines and the former for larger types, and a feature is that the machines are designed to operate at a rather lower speed than usual. The generator is controlled by a vibrator linked in so as to control the voltage of the current supplied and this vibrator, together with the automatic cut-out, is mounted in a neat case that attaches directly to the generator itself.

For the starting motor of the two-unit system the Bendix pinion is the preferred drive and the makers claim that the motors they select for the automobiles supplied with their system are capable of cranking at a speed which is above the normal.

Bijur Has Special Regulator

The Bijur equipment was described in THE AUTOMOBILE of Oct. 28, 1915. The main changes for the coming year are that the weight has been reduced and the efficiency increased, the main principle remaining unchanged. Both constant current type generators with inherent regulation and generators with vibrator voltage regulation are made, and the latter type has a special feature which has now been in use for some time, proving very satisfactory. This is the use of a vibrating reed which can vibrate in two directions. Not only does the blade vibrate up and down, as it has to do in order to make and break the contacts, but it is flexibly supported so that it can shake sideways also. The purpose of this is to allow the contact points to meet in all sorts of relative positions instead of always square together, the idea being that this spreads the slight wear and prevents any danger of pitting.

The saving of weight has been brought about by using seamless steel tube to make the outer shell of the machines, the pole pieces being screwed on after the windings are in place. This makes the generators and motors of neat exterior appearance and is frequently of assistance in fitting to an engine. Accessibility is well cared for, but the cut out and voltage regulator on that type of generator are sealed up in a case which is attached to the generator shell. Should any trouble be traced to this portion of the equipment it can be removed as a unit without touching any wires, and replaced with another, the regulator base being of standardized form, and the makers will attend to the faulty apparatus if returned with the seal unbroken.

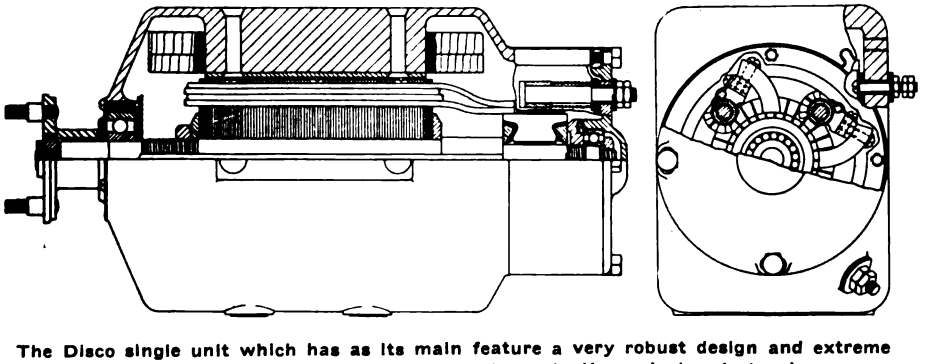
Aplco Single and Two Unit

Made by the Splitdorf Co., the Aplco machines are of both single and duplex type. The motor generator has been developed to a high pitch of perfection and is found on one car in an almost unique position, this being alongside the gearset. When acting as a generator this machine operates at 6 volts and is thus usable in connection with the preferred 6-volt lamp equipment. When acting as a motor the connections are such that 12 volts are supplied from the battery and the starting torque thereby enhanced.

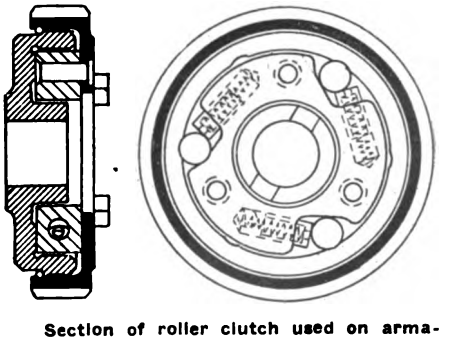
Regulation is performed by a compound winding with reversed series coils and the arrangement is such that both series and shunt windings are used for the starting current. As a single unit machine operating on two voltages it is necessary to have an automatic cut out, and this is part of the equipment. Features claimed as peculiar to this outfit are light weight and high efficiency.

Dyneto Prefers Single Unit

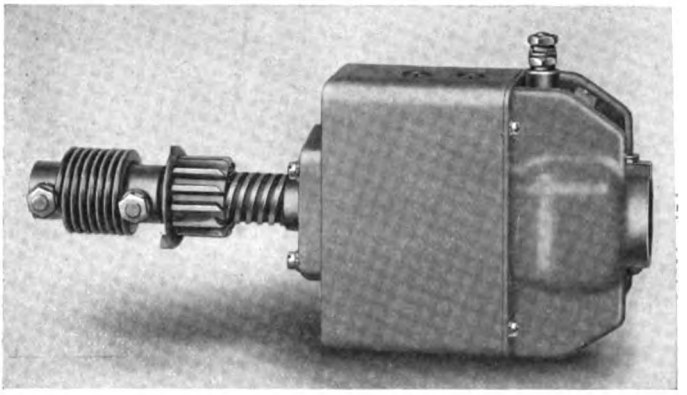
For 1916 there will be available four Dyneto systems, two of the single unit type and two of the double unit. The manufacturers express strong preference for the single unit, believing that its simplicity which is very great, overcomes any other advantages which may belong to the two-unit sys-

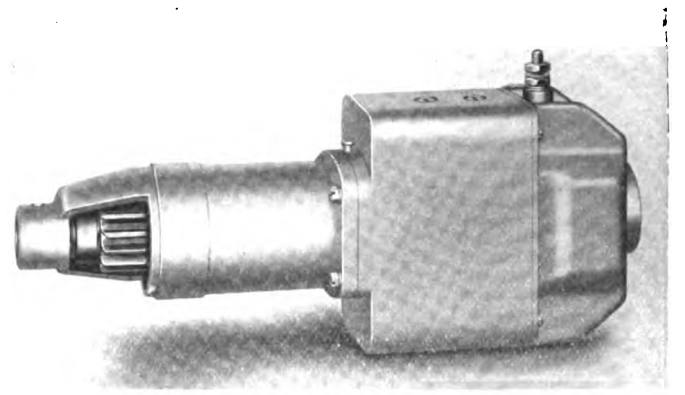


The Disco single unit which has as its main feature a very robust design and extreme simplicity. The purpose of the curved brushes shown in the end view is to give square contact with the commutator



Section of roller clutch used on armature drive in Delco single unit equipment shown on page 1002





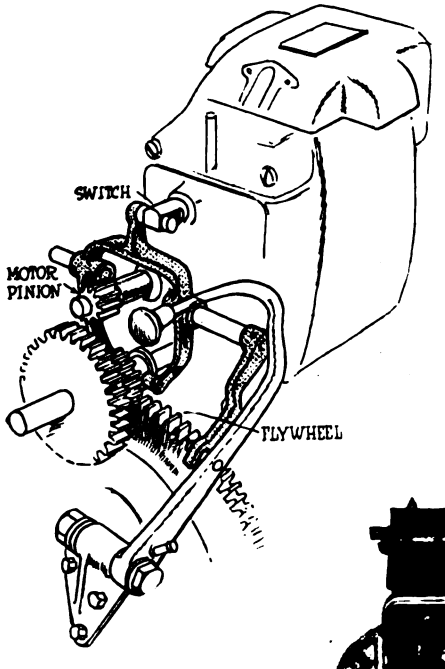
Gray & Davis starting motors with Bendix pinion drive. That on the right is provided with outer bearing for support of shaft extension

tem. Regulation of output is by compound winding with reversed series coils and the voltage is 12. There are no automatic cut-outs so the battery drives the gasoline engine automatically if the latter should stall, recommencing generation directly the engine picks up again. Changes for the coming year have been quite small and center mainly upon means for attaching the single unit machines which have been improved so that the fitting to a variety of different engines is facilitated.

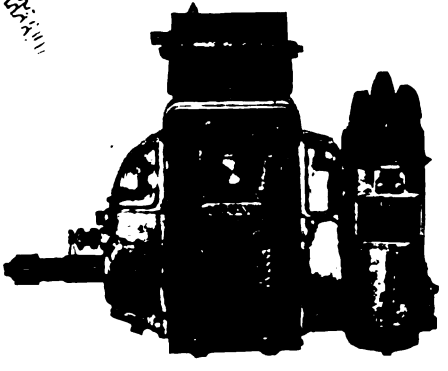
Geared with the crankshaft at from 2.5 to 3 to 1 the starting torque developed is large and cranks the engine at a rapid rate. No attention whatever is needed beyond oiling and occasional adjustment of the chain when this form of drive is used, and it is the recommended drive.

Auto-Lite Have No Novelties

Known, perhaps best of all by reason of the enormous number of systems fitted to Overland and Chevrolet cars, the keynote of Auto-Lite two-unit equipments has been simplicity. For generator control the reversed series winding is employed, this reducing the mechanical attachments to a simple cut-out of ordinary design.



Left—Diagram of Delco single unit system. The switch is operated by the same pedal that shifts the gears into mesh. Below —Delco lighting, starting and ignition unit



The Auto-Lite generator is of very distinctive design, having magnets shaped like those of a magneto with the winding coil concentrated upon the arch of the horseshoe. In the Auto-Lite factory there is an immense press plant for cutting out and shaping parts of sheet metal, and the field magnets are, consequently, made up of laminations like the armature.

This press plant is utilized to the fullest advantage in order to produce the equipments with a minimum of weight and without undue expense, in fact it is a most striking example of how very much manufacture can be simplified by the ingenious employment of pressed parts. Not only are these used for laminations, but switch parts, casings, covers, etc., largely come finished from the press room and need no machining. It is noticeable that practically all machine work in the plant is on small parts like screws and terminals.

No new models are announced for next year, the machines produced twelve months ago being continued. Generators of similar design are made in several sizes and there are several models of starting motor to suit different applications.

Disco Is Single Unit

Two sizes of single unit motor-generator makes up the Disco line at present, but it is expected that a two-unit system will be announced shortly, the company considering that both types will be permanent. Rather an unusual feature for a single-unit machine is the use of a vibrator form of controller which restricts the current output at high speeds and is, of course, cut out entirely when the machine operates as a motor. The Disco Co. draw particular attention to their brush gear which is very accessible for examination, while the brushes can be removed for the purpose of cleaning the commutator at the rare intervals when such attention becomes necessary. It is claimed that the brush wear is extremely slight owing to the excellent commutation, which is assisted by the regulating system.

U. S. L. Only Flywheel Starter

The only flywheel dynamotor now standardized as regular equipment on any well-known automobile is the U. S. L., which was one of the first systems to be produced. For 1916 the system has been improved in detail quite considerably by a large reduction in the number of parts and simplification of detail. In this machine the armature forms the flywheel of the gasoline engine and it is surrounded by the field coils which are, of course, stationary.

Regulation is on the inherent principle and is so arranged that the maximum charging current occurs at a low engine speed, the rate of charge falling off as the speed rises. A special switch is provided by which the current can be cut off altogether for long, high speed runs to prevent the battery receiving an overcharge.

An especial improvement for 1916 is the provision of an

electrically operated relay switch for starting. All switches, fuses and connections are now concentrated upon the cowl board attachment and pressing a small button sends a small current through a relay coil which then operates a powerful magnetic switch and throws on the full starting current. The new device not only removes the necessity for a foot actuated switch, but overcomes any danger of burning the switch contacts, by reason of the instantaneous action of the magnetic switch.

Two Types of Allis-Chalmers

Both single and double unit Allis-Chalmers systems are made, a vibrating reed current controller being employed for both types, and 1916 changes have been mainly along the line of improved mechanical detail and reduced weight. Greater accessibility has been secured through changes in the brush holder and commutator design and weight reduced from 15 to 17 per cent by refinements which permit reduction of waste material.

For detail equipment there is a new cowl board panel upon which all the switches and the ammeter are grouped and this panel also carries every wire necessary except the main leads to battery and lamps. Thus wiring is simplified and the ease of fitting enhanced, while reliability is increased. All the connections to outer circuits are made in the fuse and terminal compartment wherein each connection is clearly marked and tracing any wire consequently made perfectly easy.

Another improved detail is the starting switch which is foot operated. The contacts are heavier and yet the whole part is lighter, and additional protection against ingress of dirt or water is given by a tubular cap which covers the plunger.

Wagner Builds to Order

Wagner starting equipments are not made in standard form but are designed to suit the needs of automobile manufacturers and may vary in detail accordingly. Only two-unit systems are made however, this being practically the only limitation.

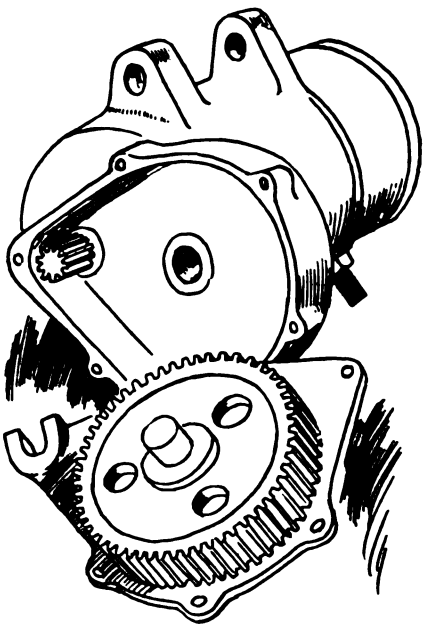
An almost unique feature of one of the best known Wagner outfits is found in the starting motor used on the Studebaker car as this has a double reduction gear. Made integrally with the starting motor is a case containing a pair of steel gears giving a reduction of about 8 to 1, and it is to the spindle of the large gear that the engine drive is connected. This double reduction permits the use of a very high speed, small and light motor.

Bosch System New

As the Bosch system just introduced was described last week in full, there is no need to repeat the account here. The new set is called the Bosch "Standard" and consists of generator, motor and switch unit with a box containing the automatic cut-out separate. Regulation is by ballast coil or hot wire controller and the special features are light weight compared with neat design and fine workmanship.

Leece-Neville

Up to the present no new models of this system have been announced, the standard equipment being that as fitted to the Haynes car. This is a two-unit type, the generator having inherent regulation. The use of a 12-volt potential is now rather unusual with a two-unit system but the Leece-Neville Co. believes that it is possible to obtain higher efficiency from both generator motor with this voltage, so it has been the standard employed and is still being continued.



The intermediate reduction gearing used on the Wagner starting motor fitted to Studebaker cars

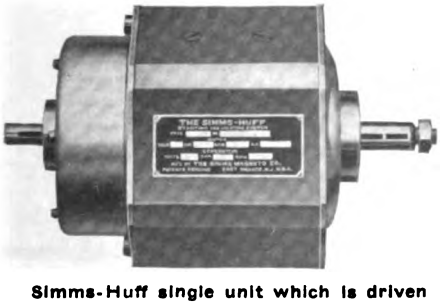
Simms-Huff Continue Single Unit

The unique feature of the Simms-Huff system is that it is a single unit with two connections to the engine. Arranged to be driven by belt or any other approved method it operates as a generator with inherent regulation, charging at 6 volts. When operated as a motor, a 12-volt current is used and an over-running clutch is employed to prevent interference between one drive and the other. Having the ability to operate at a high speed for starting, the weight of the unit is not great, in fact it is extremely small, it being stated that a machine weighing but 30 lb. can exert a starting torque of 24 lb. The brush gear is of ingenious design, only one wire being used to make connection. Being hexagonal in shape the unit is also short, and its compactness allows it to be fitted in a very confined space.

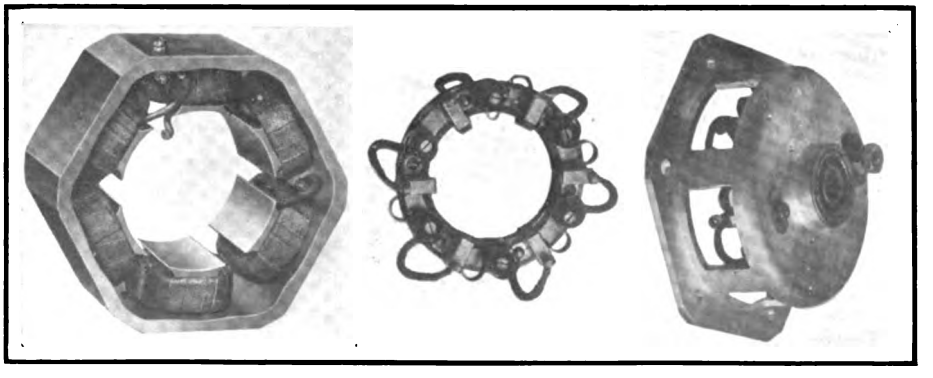
In Conclusion

In concluding this brief review of the most widely used lighting and starting systems it should be again emphasized that it has only been attempted to include those which are employed extensively by automobile manufacturers as standard equipment.

There are a very great many other systems which can be applied to standard modern cars or to old cars, in fact most of the systems which can be bought one at a time are different from those which are used as standard equipment. It is hoped to review these at a later date.



Simms-Huff single unit which is driven at one end and drives for starting from the other



Right—Details of magnet windings and brush gear of Simms-Huff single unit

Increasing Activity in Axle Field

Many Small Changes in Design—Return of Semi-Floating Type—Gear Ratios Touch Bottom—Brake Problems—Contest Between Different Drives for Trucks

By A. Ludlow Clayden

THE rear axle arrived at a state of comparative perfection only quite recently, in fact it is probable that there is much more room for development still existing in the axle field than remains in the sphere of the clutch and gearset. The earliest "live" axles suffered from the ill effects of poor design and unsuitable material, they were apt to fail altogether by actual fracture of some part. As soon as the engineers and the steel makers had found means to overcome these troubles, there arose the noise question. This is almost finished with now, apparently, but to replace it there is the new demand for decreased weight. All the time the price obtainable has been falling steadily, so altogether the lot of an axle manufacturer is not the happiest imaginable.

Fundamental Types

Taking the expressed opinions of some of the leading axle makers on the question of the probable future popularity of semi-floating, full-floating and the intermediate types of axle shows that the protagonists of the three divisions are about equal in number. The following are interesting as answers to the question: Do you consider that there is a present trend toward semi-floating axles? If so, what do you regard as the explanation?

American Ball Bearing Co.:

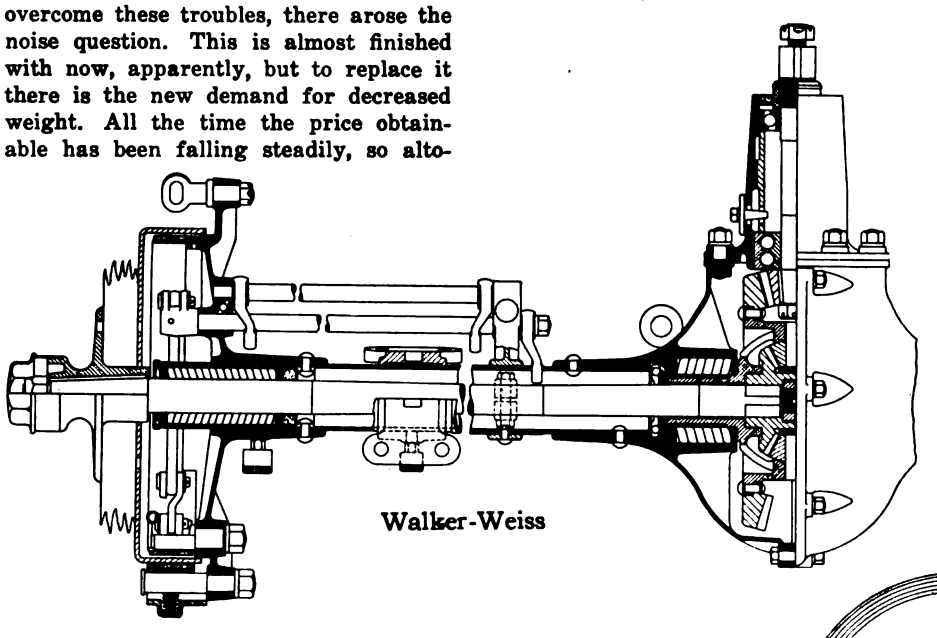
"Prefer full-floating."

Hess Spring & Axle Co.:

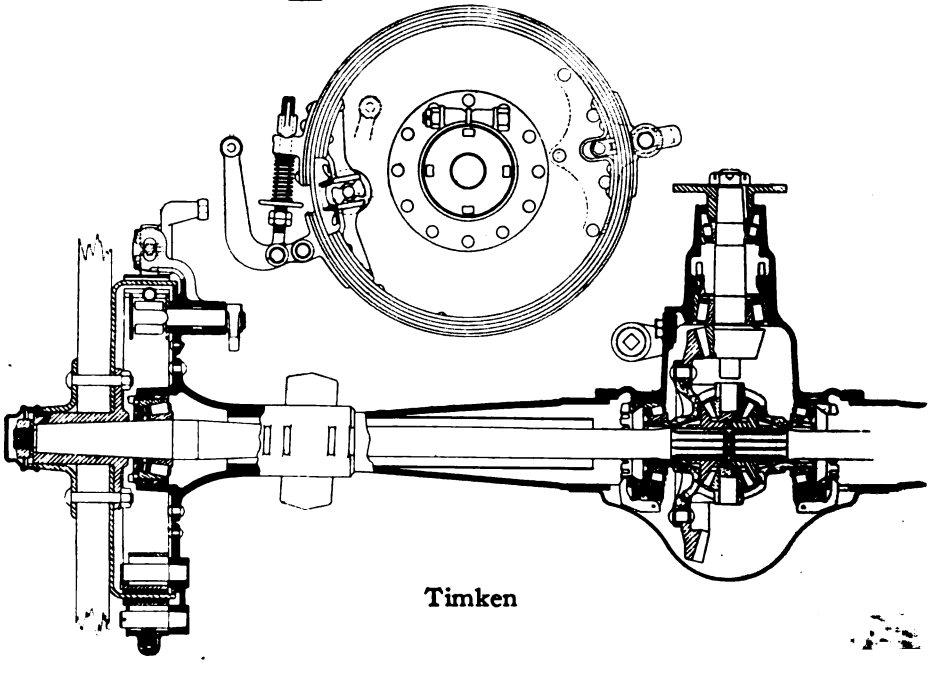
"We do consider that there is a present trend toward semi-floating axle. The only thing against the semi-floating axle is its name. The average buyer gets "cold feet," so to speak, when the agent tells him that the car is equipped with semi-floating axles. If the word semi was omitted, it would leave an entirely different impression. The buyer gets the idea that he is only getting half an axle. Our explanation for the trend toward semi-floating axles is principally because they can be made cheap. In the second place, theoretically they are easier on wheel bearings. The constant demand for cheaper and better equipment will undoubtedly bring the semi-floating into its own very shortly. If properly designed it is absolutely the best axle that can be made."

Peru Auto Parts Mfg. Co.:

"We do not feel there is a tendency toward returning to the semi-floating

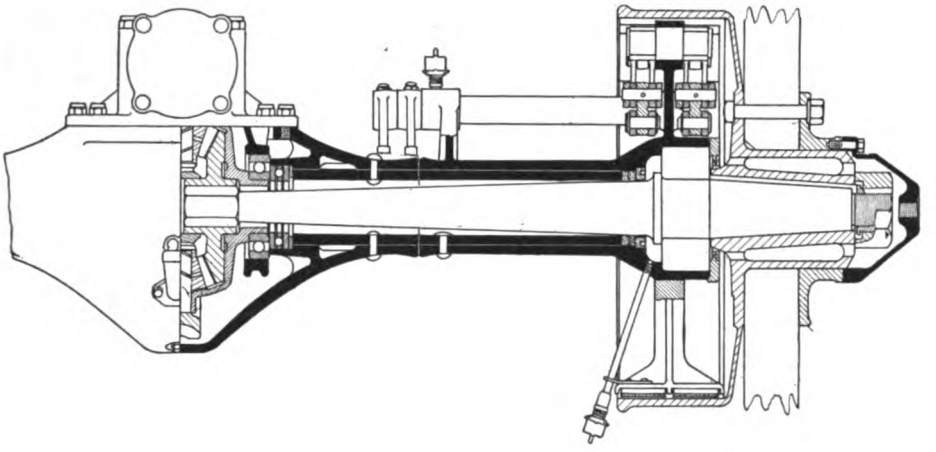


Walker-Weiss



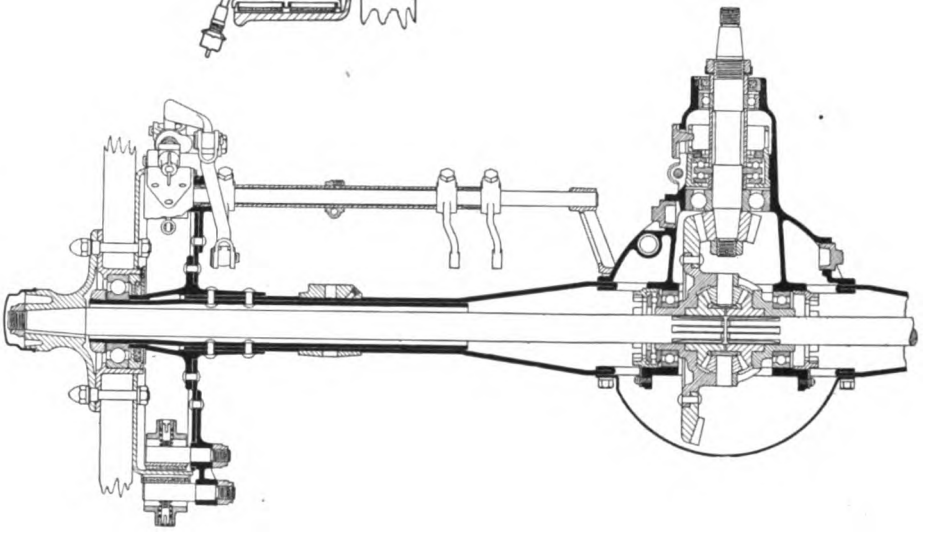
Timken

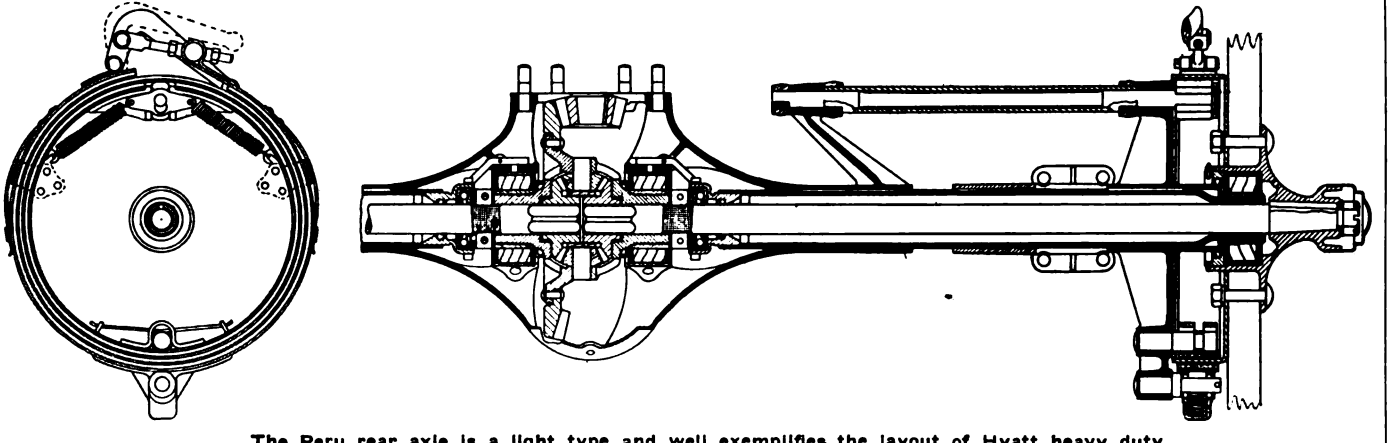
These two cuts of the Timken and Walker-Weiss semi-floating axles show two principles of construction. The former has a pressed steel case to which the whole differential assembly is bolted; the latter uses the differential assembly as the center case of the axle. In the Timken four taper roller bearings support all loads and thrusts on the driving shafts while two more carry the bevel pinion. In the Walker-Weiss the bearings that carry the load are very long, small diameter Hyatts and ball thrust washers are provided to resist end stresses. In the end view of the Timken brake, attention may be called to the light weight and the simple thumb nut adjustment for the outer band. On the cam which operates the expanding band sufficient lift is provided to enable the lining to be used up almost completely



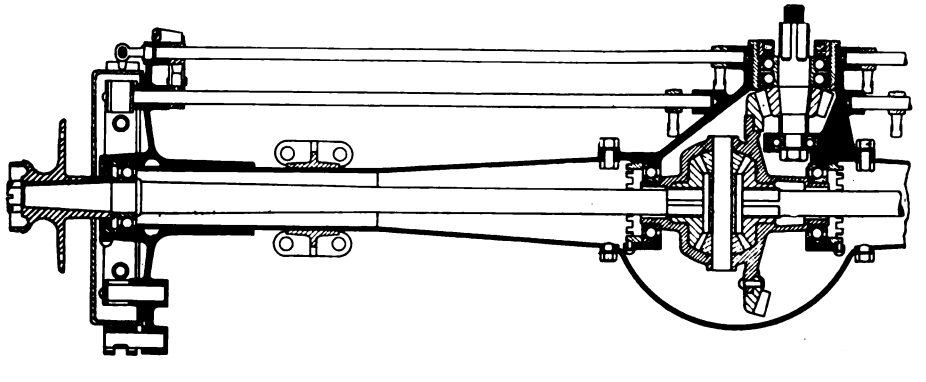
The Sheldon semi-floating truck axle is one of the heaviest constructions made on this principle, though it is claimed to be conspicuously lighter than the majority of worm drive truck axles of the full-floating type. It is equipped with ball bearings and has two internal brakes located side by side within the same drum

This Columbia axle is an example of three-quarter floating design, the single ball race on the end of the axle tube being in the plane of the wheel. Weight is carried by the tube, but the wheel is steadied by the drive shaft. A feature of this axle is the use of a very large double thrust race behind the bevel pinion, and it will be noticed that the differential assembly is made up independent of the axle casing. Bronze bushings are used for the brake operating shafts to prevent rusting and consequent sluggish action

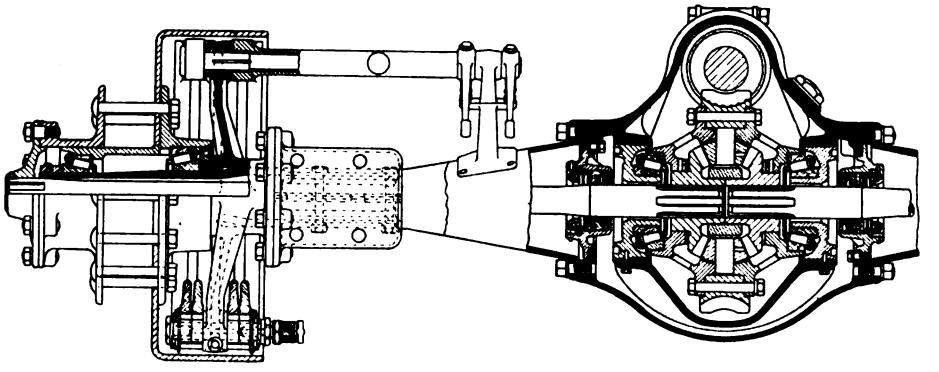




The Peru rear axle is a light type and well exemplifies the layout of Hyatt heavy duty bearings in axle construction, thrust being taken by ball bearings on either side of the differential. This axle is an example of built-up construction which the makers consider to be lighter and more satisfactory than the pressed steel type so far as small car work is concerned



The Hess axle typifies the pressed steel pattern as applied to light cars and the makers consider it to be simpler than the other type where the casing is a built-up job. On the question of weight they say there is little to choose, pointing out that a pressed axle needs no tie rod. In this axle the brake operating rods are longer than usual, but the method of mounting them does away with a bracket and so saves some weight



A worm-driven truck axle made by the American Ball Bearing Co., notable features are the double expanding brakes and the use of Bock taper roller bearings throughout. It should also be noticed that the worm and the worm wheel are mounted in the center case of the axle and the former is not removable from the wheel without taking down its mounting. This is a full-floating design all the weight being carried upon the tubes

construction. About 75 per cent of our rears are full-floating and balance three-quarters."

Salisbury Wheel & Mfg. Co.:

"No calls at all for semi-floating axles."

Sheldon Axle & Spring Co.:

"We do not manufacture anything but semi-floating axles and very few for the pleasure car trade, devoting our energies exclusively to the truck requirements. There is no more reason for a full-floating axle on a heavy automobile truck than on a locomotive. If locomotive engineers had to design a full-floating type, the bearing equipment would have to be so extremely large that there would be very little room left for spokes between the hub and the felloe.

"One has only to stand beside the railroad tracks and see a locomotive coming around a curve at 40 or 50 m.p.h., to see how very important it is to make as large a spread of bearing as possible. Very similar conditions are realized in motor truck operation. Sheldon was the first to use the semi-floating on anything above 2 tons. Their latest 5-ton axle has a factor of safety built into it very rarely realized in this form of drive.

"Where the wheels are pressed on to a tapered driving shaft, the demountable feature is also quite an item, particularly when the changes of tires are fairly frequent. If these changes have to be made in an ordinary garage with a pressed-on type of tire, the wheel has almost always to be taken off and with the full-floating type of axle the bearings are usually thrown on a dirty floor and put back with an improper adjustment, and in the case of the semi-floating, the wheel can be taken off without disturbing the bearing mounting or losing the oil in the least, and this is certainly a marked advantage over the full-floating type."

Timken-Detroit Axle Co.:

"Reduction in cost, accompanied with no reduction in serviceability."

Walker-Weiss Axle Co.:

"The general trend seems to be going toward the semi-floating type although in general we believe that the three-quarter floating type is somewhat better. The semi-floating type is liable to be a little better and cheaper to machine and makes a better manufacturing proposition."

Weston-Mott Co.:

"We do not believe a semi-floating axle is as good as the three-quarter or full-floating, one or two hub-bearing type, as in the semi-floating axle the shaft has to stand not only the torque but the weight of the car, while in the three-quarter and full-floating the shaft practically carries no load at all."

It is to be noticed that among these opinions at least one manufacturer expects the semi-floating type to come into general use for trucks. Of course there is no question but that either or any type will prove more than strong enough with modern design and modern steel.

Hotchkiss Drive Gains

It is not necessary to quote any figures to show how greatly the Hotchkiss drive is gaining in favor, the chassis descriptions published in the past year show this. Of course it is a great advantage to eliminate the weight of torque or radius rods and also remove their ever-present tendency to rattle; modern springs seem well able to care for the additional work imposed upon them by the driving stresses. Another advantage, from the owner's viewpoint, is the elimination of the spring table bearing which is obtained by securing the table to the axle in the way necessary for the Hotchkiss construction. The separate table needs lubrication where it rocks on the axle and is liable to squeak if neglected. Against this advantage we have the drawback of the necessity for two universals, but this is itself an advantage because the two joints give a better action than one alone. Altogether simplicity and all that it means to manufacturer and user is on the side of the Hotchkiss arrangement.

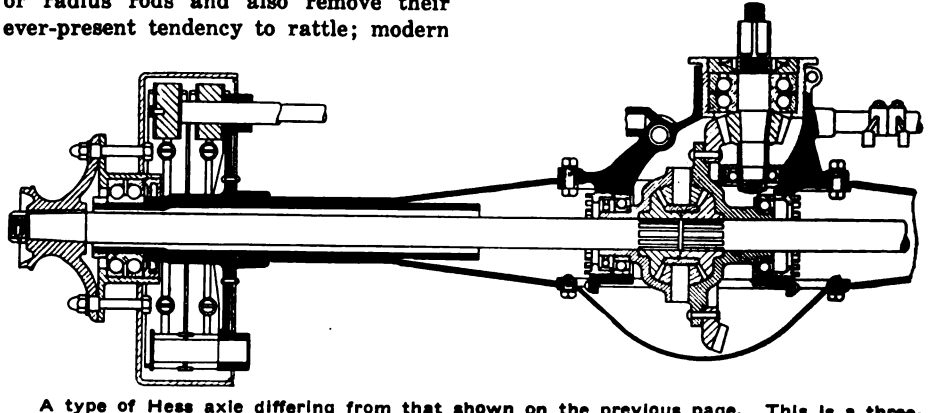
Gear Ratios Touch Bottom

When the spiral bevel came along it seemed that the noise trouble was overcome for ever by simpler means than the substitution of a worm gear for the straight bevel. The spiral bevel is a vastly better manufacturing proposition and gives a quietness so nearly equal to the worm that the difference is not worth considering. Then high gear ratios began to fall and with an approach to five to one the limit for the spiral bevel came in sight, since to go below this ratio calls for a large diameter and clumsy differential case. However, it is the opinion of axle manufacturers generally that gear ratios have touched bottom and that the cars of 1917 may be geared a little higher again than is the rule now.

This means that the spiral bevel is going to hold its sway and will probably completely displace the straight form just as soon as enough machines can be built for making the gear. At present there are thousands of straight tooth bevel cutters in existence for each spiral machine, and it will be some time yet before there are enough spiral cutters to take care of the needs of the automobile industry.

Worm V Internal Gear

In the truck field the situation between worm and internal gear drives is just



A type of Hess axle differing from that shown on the previous page. This is a three-quarter floating pattern but is otherwise similar in general respects. In this drawing the spigot bearing for the bevel pinion is shown very clearly. This feature of design is not very popular, but it certainly gives excellent support to the pinion and makes the outside of the axle very neat. It will be noticed that double internal brakes are employed

commencing to be interesting. Till quite lately the heavy field has been taken care of almost solely by the makers of worm gear axles, and the light trucks have been supplied mainly by the internal gear firms. There have been, and still are, only a few heavy pattern internal gear axles available, and there are correspondingly few worm axles suitable for *light* trucks. Thus the two types have developed side by side without much competition, each holding its own field and each giving great satisfaction.

Now the two are beginning to overlap a trifle and in the next two years the respective spheres of the two forms ought to be defined finally and conclusively.

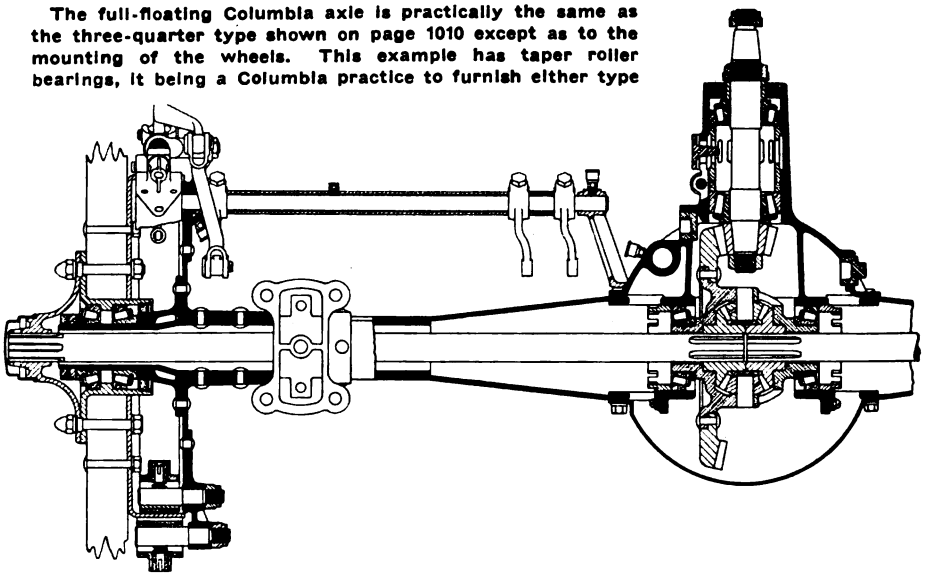
Without doubt, fashion has had something to do with the great rise to popularity of the worm gear for trucks of 3 ton capacity and over. Undoubtedly simplicity, ease of changing ratios and smaller susceptibility to abuse by neglect has encouraged the internal gear form. The pros and cons of each type are so intimately wrapped up with the service of the vehicle that it is going to take a couple of years more before any definite conclusions can be anticipated.

It may be—in fact it probably will be—that neither type of truck drive will become universal, but that both will continue to exist side by side, the advantages of the worm deciding its special field of application, and those of the internal gear fixing its sphere.

Ball or Roller Bearings

As to the relative advantages of ball bearings and of the various types of roller bearings, axle manufacturers are divided into as many sections as there are bearing patterns. The question is sometimes decided, apparently, by the limitations of space produced by other features, by cost, or by abundance of supply. In the axles illustrated on these pages almost every sort of bearing combination can be seen.

The full-floating Columbia axle is practically the same as the three-quarter type shown on page 1010 except as to the mounting of the wheels. This example has taper roller bearings, it being a Columbia practice to furnish either type



Some axle makers pin their faith to bearings of not only particular type but of particular make, this being where long experience has shown the reliability of the product in question. Others are prepared to supply either of several types and almost any make according to the desires of their customers.

The only possible conclusion is that each of the types of bearing used is capable of giving full satisfaction. Ball bearings of all sorts, taper roller bearings and roller bearings with parallel rollers depend upon the materials and upon the accuracy of their manufacture for durability and efficiency. A good one of either type is better than a poor one of any other, so with the quality of workmanship at the wonderfully high standard it has reached in America today the axle engineer is safe in following his personal predeliction.

Pressed-Steel and Built-Up Housings

In a similar way different axle makers prefer different methods of construction, some supporting the built-up axle while others prefer the pressed-steel. Where output is not very large the pressed-steel becomes the more expensive type without any question, but with large quantities it seems that there is little or nothing to choose on the score of cost.

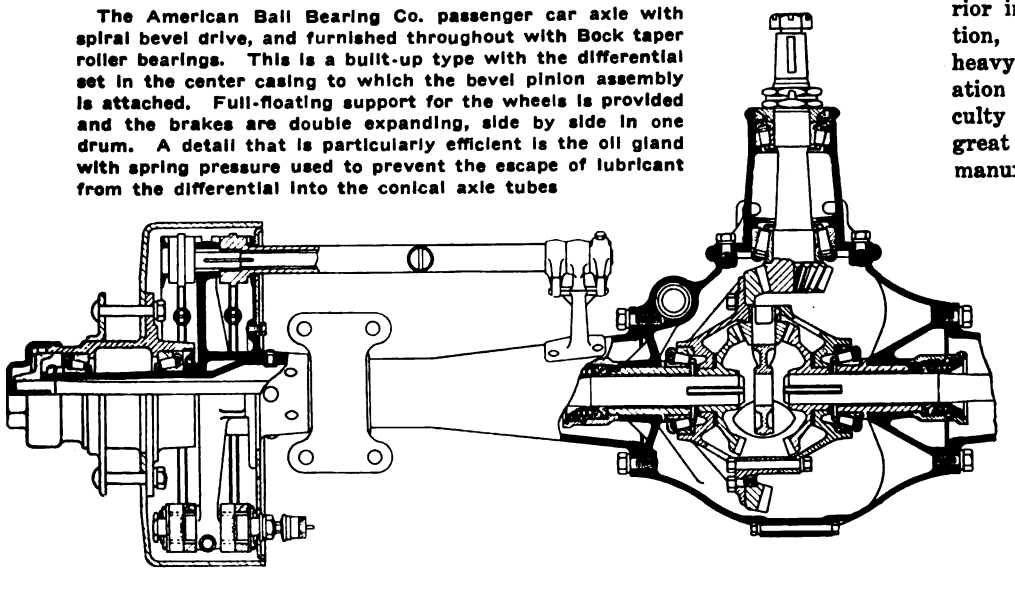
Naturally the manufacturers who have always used one type or the other prefer that with which they have had their experience, but when they make both their opinion as to which is the most advantageous is that it depends upon the exact circumstances of the case.

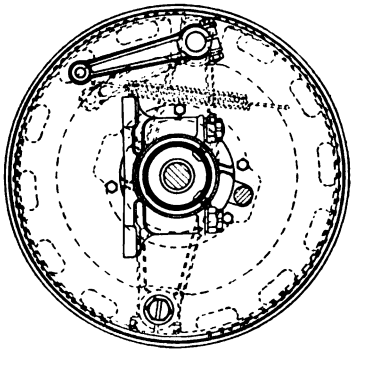
Brakes a Problem

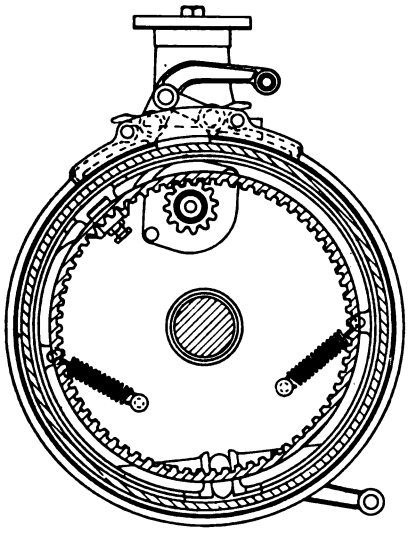
It is hardly possible to consider the question of brakes without going outside the specialized field of axle manufacture and observing the practice of the lesser number of automobile manufacturers using special designs. Of course the combination of internal band brake connected to the hand lever and external band to the pedal is still by far the most popular design, but there will be one or two more propeller-shaft brakes this year and a few more cases where double internal brakes on the axle are employed.

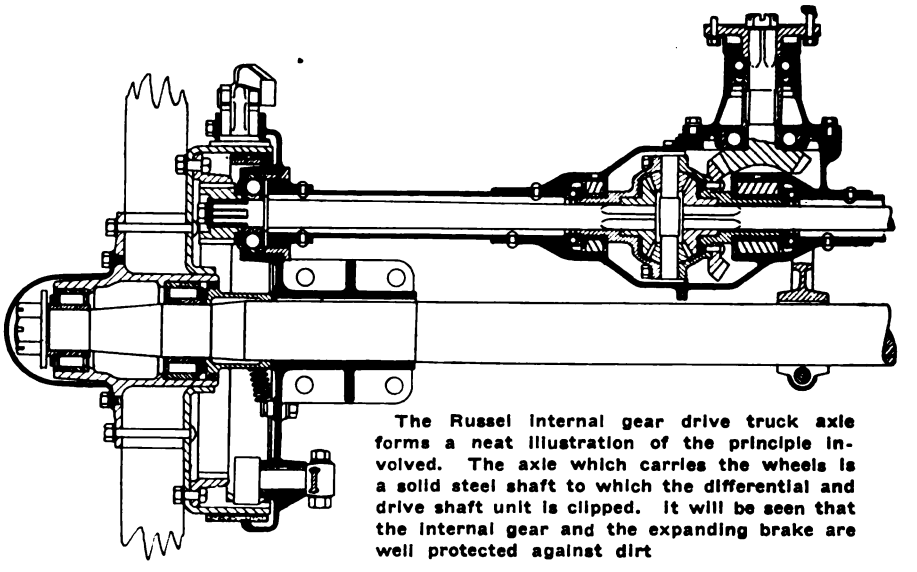
Brakes are a much neglected part of an automobile; they are infinitely inferior in design to almost any other portion, and their inefficiency is taking a heavy toll of life. The probable explanation is that there is considerable difficulty in making a brake which combines great power, smoothness and reasonable manufacturing cost. The band brake

The American Ball Bearing Co. passenger car axle with spiral bevel drive, and furnished throughout with Bock taper roller bearings. This is a built-up type with the differential set in the center casing to which the bevel pinion assembly is attached. Full-floating support for the wheels is provided and the brakes are double expanding, side by side in one drum. A detail that is particularly efficient is the oil gland with spring pressure used to prevent the escape of lubricant from the differential into the conical axle tubes









The Russel internal gear drive truck axle forms a neat illustration of the principle involved. The axle which carries the wheels is a solid steel shaft to which the differential and drive shaft unit is clipped. It will be seen that the internal gear and the expanding brake are well protected against dirt

has never, in any form, been entirely satisfactory unless made very large, and consequently heavy and clumsy, while however well it is made it needs constant adjustment to keep it in proper condition, and the number of links and joints provide opportunities for lost motion and an ever-present weakness under the increasing attacks of dirt and water.

It is notable that the layout of brake-operating rods on the chassis has improved greatly this year; there is far less spring in them and less joints, but the axle brakes remain practically unimproved.

From some points of view the double internal brake is ideal, as it is easy to inclose and can be very smooth and powerful if provided with heavy rigid shoes. But it must essentially cost more to make, and it is liable to be distinctly heavy, while the necessary width of the drums is often excessive and troublesome.

Laying Out Chain Camshaft Drives

The Principles Involved Discussed, and Some of the Problems

By F. L. Morse*

THE call for chain-driven timed shafts in the automobile probably first came because of its flexibility as to center distances, as evidenced by the International Harvester Co.'s application on overhead camshafts in 1908. Here the centers were long, and the chain was the easiest way to drive the camshaft, so upwards of a thousand were thus equipped. Next its use was suggested as a remedy for excessive noise, or what passes for the same fault—a regular variation in the noise so often found in gearing, as it is found nearly impossible to get a pair of gears exactly true mechanically and in tonal qualities.

The silent chain met these requirements of flexible centers and quiet operation, but brought a different trouble in its train, viz., short life due to the lengthening pitch. This was not a matter of chain destruction as understood by the chain maker, but rather of design or special application, as the accumulated lengthening of but 0.003 or 0.004 in. per pitch permitted the chain to become so loose as to strike some interfering point, and it was for this reason that removal was required.

This lengthening, however, of 0.003 or 0.004 in. per pitch is but a small percentage of the total life of a chain if adjustment had been provided, and, as a matter of fact, little trouble would be found from lack of correct timing until the chain had lengthened six times this amount, or 0.024 in. per link. However, thousands of drives had been put out with non-adjustable centers, notwithstanding every chain maker knew the desirability of and recommended adjustment. It was imperative that a chain be furnished that would lengthen less rapidly in order to give a reasonable life to the car user, so the chain makers immediately commenced to better their product.

The first and easiest expedient was to what is termed run the chain in, i.e., to take out the initial lengthening that would come from quick smoothing up and seating home of the joint parts in the punched holes in the links. Then followed as promptly as possible experiments to get more suitable steel and refinements in the process of manufacture. This was accomplished to a large extent within a year or two, so that then these early applications of chains to automobiles on a whole proved fairly satisfactory to all concerned, the average life being between 10,000 and 20,000 car miles. The chain then several years ago became a competitor for gears for the timed shaft drives on gas engines, and at an initial greater first cost, which indicated some added desirable feature, and a comparison between the two forms of transmission may indicate the future trend in design, which, I understand, is of particular interest to the automobile engineer.

In the general description of silent chains you have been told (1) that the chain contacts with and drives through all the teeth embraced by the chain, and (2) that it rises higher on the teeth as the chain lengthens, thus maintaining its correct pitch diameter, and (3) that it is only the free chain in between the sprockets which affects through its lengthening the angular relation of the two shafts. As a matter of fact, these statements are only partially true as far as the Morse chain is concerned, and, being interested in that product, I

*From a paper read before the Indianapolis Section of the S.A.E., November, 1915. Mr. Morse is president of the Morse Chain Co., Ithaca, N. Y.

will only speak of its action, as possibly a discussion may bring out the action of other products and wherein they differ, if at all, as I trust representatives of the chain makers are here.

The links of the silent chain contact with the sprockets at an angle greater than the angle of friction, and therefore tend to slide up the tooth, and the distance from engaging point to engaging point being obviously greater on the larger diameter, this action in effect compensates for an increasing pitch. Further, the engagement with the tooth is at a point below the line of pull, so there is also a lever action that tends to maintain the chain at a point higher than its true pitch, in addition to any centrifugal force that may exist.

Three Forces on Chain

We have, then, three forces that tend to slip the chain outwardly and over the teeth, requiring a definite opposing force to keep it on the teeth. Part and sometimes all of this restraining force is represented by frictional resistance to sliding up the teeth, it being a matter of the number of links in engagement on, as well as the size of the sprocket, varying with different sized wheels. Experiments have shown that five to thirty teeth in engagement are sufficient to keep the last link away from the direction of pull from raising on the tooth with any appreciable force. (The number of teeth in the wheels can be reduced so all except the first tooth engage with less than the angle of friction, but under these conditions the drive does not operate quietly or in accordance with the general design of silent chain.) If, then, more than this number of teeth engage the chain, it will float between the teeth, not touching either face, till the tension—there always being more or less—of the slack side pulls the chain against the idle or non-driving face of the teeth.

Drive Force Is Tension Difference

The effective driving force of the chain is the difference between the tight and slack strands, the same as in belting, and something of the same "creep" that is found in belting takes place on the tooth faces, as the chain is driving through frictional contact with many teeth. The drive gives a positive speed ratio because, either by friction against the teeth, or tension on the slack side, or both, it is prevented from going over the top of the teeth, while it still drives through frictional contact with, and has a slight movement on many teeth. The first tooth in engagement with the chain on the tension side is taking the largest share of the burden of driving, and the chain rides higher on this tooth than on the next tooth back, due to the angle of pull to the face of the tooth, and also because the chain is slightly elastic, and, due to the tension, is longer at this point.

At each successive tooth the lengthening due to elasticity decreases, due to the lesser tension, and also due to a lessening tension the chain gradually creeps down the tooth on the driving wheel until it gets to a point at or below its pitch diameter. Under these conditions the chain is drawing a spiral on the sprocket, the larger diameter on the driver at the entering tooth, on the driven at the leaving tooth, while the smaller diameter may be anywhere between these points and the leaving or entering tooth of the driver and driven respectively, depending on the number of teeth engaged by the chain. If these statements are correct, it follows that only a limited number of teeth on the chain wheel may do the driving, not all in contact with it, and as a corollary that it is always desirable to have this minimum number of teeth engaged by the chain. The distribution of the tension necessary to drive over a number of teeth is what makes the chain so quiet in action, as the taking up by the links of the pressure of driving is gradual and produces no blow effect.

The lengthening of the chain, and particularly that portion in tension between the chain wheels, causes a change in the angular relation of the connected shafts, and in camshafts a lag in timing is obvious. In addition to this, on account of the tooth face being at an angle to the line of pull, when the chain has lengthened and climbed higher on the tooth, this has permitted the wheels also to lag slightly more, but this is the worst that can be said, and can almost be neglected.

Details of Typical Layout

For instance, there is illustrated here a typical triangular drive, crankshaft sprocket, twenty-one teeth, camshaft sprocket forty-two teeth, on 6.406-in. centers. The chain has seventy-nine links, and the Morse adjustable sprocket is used on the accessory shaft. The adjustment will take care of a lengthening of one link, when the odd link furnished can be removed and the adjustment set back to zero, thus allowing for lengthening of another link, or ½ in., or a total of 1 in. This is an extreme case, and should be good for 50,000 to 100,000 car miles. We now have a lengthening of 1 in. in seventy-nine links, or 0.01265 in. per link, the crank sprocket being 3.355 in. and cam sprocket 6.691 in. pitch diameter. The wheels are on 6.406-in. centers, thirteen links in the tension run to the camshaft wheel, and thirteen times 0.01265 in. equals 0.16445 in. as a total, which in itself permits of a lag in the timing of approximately 2.8 deg. In lengthening this amount the chain has climbed radially 0.084 in. on the larger and 0.042 in. on the smaller wheel, and this has permitted the wheel to lag 0.072 in., equaling 1.2 deg., or a total for both causes of 4 deg. This is not very serious, as I understand it, and could in any case be compensated for by cutting, say, two keyways in the camshaft sprocket, the one in correct relation to a tooth when new, the second when one link is removed, so at no time could the lag in timing amount to more than 2 deg.

On the triangular drive above referred to, there was used a chain 1½ in. wide, ½-in. P., and this drove the camshaft, with water pump and generator on the third shaft. With this arrangement the total space parallel to the crankshaft was 1¾ in., or, allowing for back clearance, 2 in., which with gearing might have been reduced to 1½ in., so the saving in room by the use of gearing would have been about ½ in.

Unless a third or intermediate gear is used, there is generally more weight with the chain drive, but this amounts to not more than 4 lb. on an installation such as above, this being the total weight of the chain. The cost of chain wheels is less than that of gear wheels, as they can be cut faster, and there are practically no rejections. A case-hardening steel

The History of the American Automobile Industry—6

Copeland's Steam Bicycle Capable of 15 M.P.H.—Anticipating the Present-Day Side Car—$500 the Maximum Price for Motor Vehicles?—Public Confidence Grows

By David Beecroft

¶ Review—In the last installment the early development of steam road vehicles in their various forms was traced up to 1880, the prejudice of the public against them being mentioned. There were a number of three and four-wheeled steam carriages, as they were called at that time, and even a steam man for drawing a wagon, the figure being fitted with a light, high-speed engine. A growing demand for mechanical power became manifest in the seventies, there being several instances where advertisements appeared offering $5,000 and $10,000 reward for the invention of substitutes for street car horses and of practical road vehicles. By 1876 the gas engine had reached a stage of development where it was attracting serious attention for stationary power and boat work and about this time bicycles became of interest to the public. ¶ This week the narrative takes up the first motorcycle—a steam bicycle—and the prototype of the present-day side car and tells how $500 was thought to be the maximum price possible for a motor vehicle. It took nearly 10 years to get the public above this low-price limit, which was one reason that the motor vehicle did not come into common use much earlier. The wide publicity given the steam bicycle, however, did much to increase confidence in the self-propelled conveyance for everyday purposes.

OF experimenters whose influence has reached down to the modern automobile movement, dating from 1880 to the present day, although not a part of it, the first position seems to be due to Lucius D. Copeland, who, 35 years ago, was living at Phoenix, Ariz. Copeland began his work in 1881 by attempting to attach some form of motor to a Columbia bicycle that would not do all the work, but would assist where the going was hard. Possibly the sands of that southwest country were responsible for this desire for help. The high-wheel Columbia bicycle was hardly a structure to which a successful application of power could be made, and he reports his first attempt as both very inefficient and dangerous. About this time, the Star bicycle, which carried the large wheel at the rear in a frame and steered by the small front wheel, appeared on the market and one was purchased by Copeland. To this, he attached a small boiler on the inclined front frame tube and fitted a small engine just below the saddle with belt to a large pulley on the rear wheel. On a good road, this device would drive the bicycle at 15 miles per hour, a very creditable showing for so small an equipment. This was finished in the fall of 1884 in time for exhibition at the Maricopa County Fair at Phoenix. Later, being anxious to secure assistance, he showed the steam bicycle at Mechanics' Pavilion in San Francisco in 1884. The engine was ¼ hp. with the weight complete, including water, as 18 lb. Later reports describe the motor as 1 hp. and able to make 1000 r.p.m. and drive the vehicle 12 m.p.h. The entire equipment could be easily removed or transferred from one bicycle to another. When the date, 1884, is considered, it will be seen that this was a wonderful accomplishment and it is another illustration of the fact that the self-moving idea has always accompanied wheeled vehicle progress.

A Company Formed

The next spring Copeland showed this motorcycle in many California cities, such as Oakland, Berkeley, Sacramento, Stockton, Napa, Suisun, Watsonville, Santa Cruz, Vallejo, San Rafael, San Jose, and other places, besides several skating rinks and exhibition halls in San Francisco, but did not find the financial assistance wanted. He then proceeded to New York, where he exhibited at Madison Square Garden and other places. After 3 years of searching with a persistence worthy of a better reward, he met Sanford Northrop, who, with Drs. Starkey and Palen, of Philadelphia,

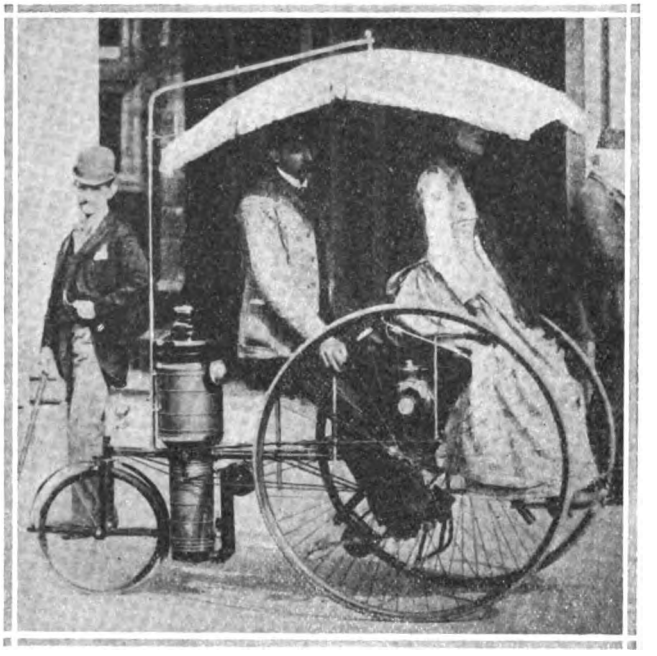
Lucius D. Copeland and his first successful steam motor, which is shown fitted to a Star bicycle of the vintage of 1884

formed a company known as the Northrop Mfg. Co., with a shop located in Camden, N. J. Here, having some capital, he was able to make improvements and 3 months later was running a steam tricycle on Camden streets. He fitted automatic water-level control and automatic fire control which depended upon the boiler pressure. He connected what would now be the brake and clutch levers by making the operation of the brake lever shut off the steam. He made many trips to adjoining towns, drove often in Fairmont Park, Philadelphia, and his longest trip was to Atlantic City, 60 miles, and return, carrying a son of Dr. Starkey as a passenger. His tricycle patent, applied for in October, 1886, was issued April 5, 1887, and covers the use of the framing tubing for an oil receptacle and the use of the exhaust steam to heat the feed water and fuel oil.

Prototype of the Side Car

In 1888 Copeland brought out a motor bicycle along the lines of the safety bicycle, which was beginning to make its appearance at that time and of which he, quite rightly, recognized the value. With his previous success, it is needless to say that this machine ran well. Afterward, he attached a wheel at one side on an adjustable reach so it could be fitted to any gage of road and on this reach was placed a seat for a third passenger, thus anticipating the modern side car by nearly a score of years.

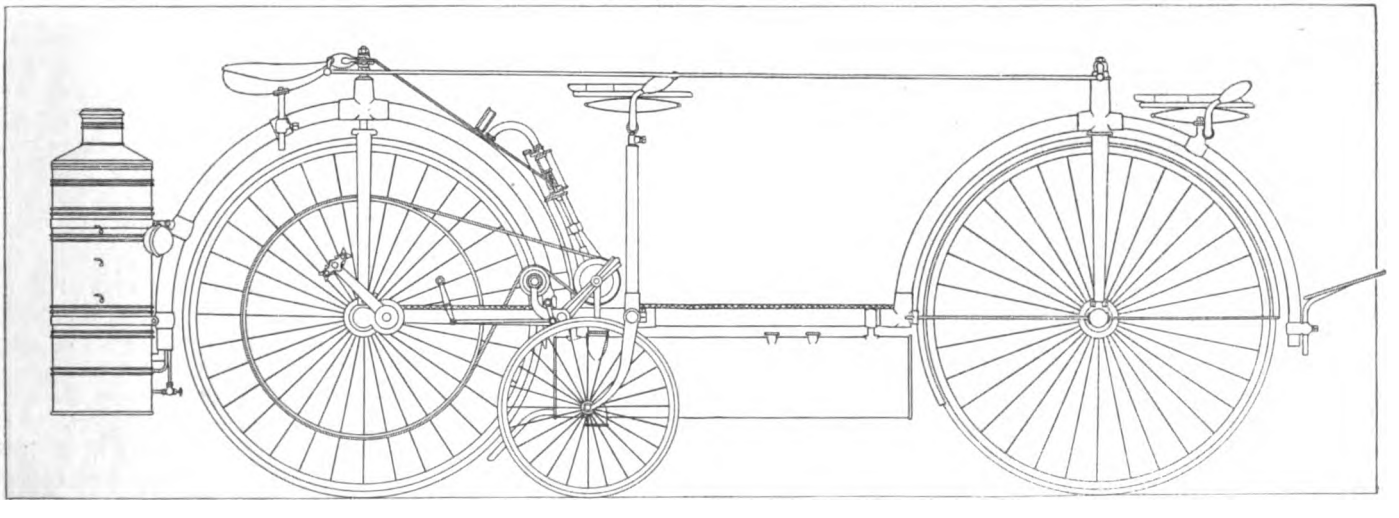
The Moto-Cycle Mfg. Co. of Philadelphia controlled Copeland's patents on steam bicycle motors, and in 1890 the vehicle produced used bicycle wheels with heavy rubber tires and a two-cylinder horizontal engine on the frame of the machine connected to the axle of the driving wheel by noiseless gearing. A safety boiler could get up steam in 5 min. and one filling of the water tank would suffice for 3 hr., or a 30-mile run. Fuel was carried on the other side of a partition in the same tank and some distance from the fire. One hand steered while the other held the throttle lever, and, releasing the throttle, stopped the engine. It is not known that any of these vehicles were sold and probably they were not.



Copeland's second machine, built in 1886, was a rear steering invincible tandem tricycle to which he fitted his steam motor

$500 the Maximum Price?

Mr. Copeland, now of Sawtelle, Cal., says he became discouraged, thinking the people would not pay more than $500 for a motor vehicle and that there would be little or no profit in the business. This coincidence of opinion in the matter of maximum price, with that of Charles E. Duryea, who, in 1891, thought $500 the maximum, probably indicates very closely the feeling of the public. It took nearly 10 years to get our people above this low-price limit. The motor vehicle would have come much earlier had they been open minded enough to have accepted it. These exhibitions and the Copeland patent with the wide publicity given by the published descriptions undoubtedly did much to give the people confidence in the steam vehicle.



Copeland Moto-Cycle to carry three passengers. The rear rider steered and controlled the machine. Starting was accomplished by foot power by means of a lever and clutch arrangement driving the rear wheel. Adjustable idler wheels on both sides served to hold the machine upright when at rest

The Rostrum

Nickel-Steel Is Stronger Than Cold-Rolled

EDITOR THE AUTOMOBILE:—Strictly speaking, what is meant by a cast steel gear? A drop forged? Are there vanadium gears in use on many cars, and which of the three are the best and which costs the manufacturer the most to produce?

2—Is nickel-steel best to use for axle shafts, and must it heat-treated? If so, what effect has it on the shaft by treating it so? Which is the best to use, cold rolled, or vanadium steel, and which costs the most to produce?

3—Is cold-rolled steel simply a mild steel, or is it alloyed somewhat differently?

4—Which of the above materials does Overland use in its model 83 cars and what does Buick use in its 1913 to 1915 cars? Also the 1913 to 1915 Hupmobile?

Plentywood, Mont. J. S. K.

—A cast steel gear is one in which the gear is a steel casting. A drop-forged gear is one in which it is a forging. Vanadium steel gears are used on a few cars, but where alloy steel is used nickel is employed to a much larger extent. The alloy steels are the most costly. Forging is the method generally carried out in all cases, the forging being a blank and the teeth afterwards cut upon it.

2—In order to secure the benefit from nickel when used as an alloy, the steel must be heat-treated. Heat-treating the steel makes it tougher and stronger and increases the elastic limit. There is no comparison between cold-rolled and vanadium steels. Cold-rolled steel is that in which the metal has been rolled into shape while cold. It is only a simple carbon steel and is quite soft, as a rule.

3—Cold-rolled steel is not alloyed with any of the substances used to increase the physical properties of the metal. If you will refer to THE AUTOMOBILE for April 8, 1915, you will find a series of articles entitled "The Pathology of Steel," which will make clear to you the points upon which you desire enlightenment.

4—Regarding the materials used in the various cars you mention, it may be stated that all three of these concerns use a wide variety for different purposes. If you will mention the parts to which you particularly refer, the information could probably be given.

Excessive Carbon in Cylinders

Editor THE AUTOMOBILE:—To what would you attribute excessive accumulation of carbon in cylinders? The compression is splendid, the level of oil is correct, and the mixture is correct. The car is a 1911 model and has seen a great deal of service. Could the cylinders have become oval or could the rings have lined up so that the openings are all in line?

2—Would it be advisable to install aluminum pistons in the above car if I had the cylinders re-ground? In this case, would it be necessary to have new connecting-rods made? Do you recommend standard pistons and rings in preference to the aluminum ones in an old car?

3—Do you know of any way to repair broken celluloid windows in a top, without replacing the same?

These questions are relative to Packard 30 cars.

Orange, N. J. N. S. B.

—The excessive accumulation of carbon in the cylinders of the model 30 car is no doubt due to the natural wear of the cylinders and pistons which have now left enough clearance between same to allow the oil to work up. Although good compression is observed and the piston rings seem to be all right, this clearance will permit the oil to work its way through. The only thing to do in a case of this kind is to be sure that the oil level in the crankcase is kept at the proper level. If the cylinders still carbonize, they should be removed and a set of reground cylinders with properly fitted pistons should be installed.

The Packard Motor Car Co. keeps reground cylinders and pistons of all sizes on hand for this particular purpose, and you can get details regarding price from the nearest Packard agent.

2—It would not be advisable to install aluminum pistons in this model as the complete design of the motor is not intended for high-speed reciprocating parts and you would be apt to run into clearance difficulties. It would probably be more satisfactory in an old model of this sort to use the standard pistons and rings.

3—THE AUTOMOBILE has no record of any satisfactory method of repairing broken celluloid windows. It is easy enough to replace them by simply ripping out the stitching around the windows, put in a new piece of celluloid and stitching in the old seam.

Using Generator for Battery Charging

Editor THE AUTOMOBILE:—Would it be possible for a Wagner lighting and starting generator taken off a Studebaker 35 (the cutout relay being out of order, would have to be done away with), to be used for charging batteries, to be run by a stationary gasoline engine? If this could be done, please give instructions as to controlling charges and at what speed it should be run. Also any other information on the subject which would be of any help.

Sussex, N. B. H. W. S.

—This equipment can be used to charge six-cell lead batteries by closing the relay points permanently and arranging the engine drive so that it will run the generator from 1600 to 1800 r.p.m. The controller should be placed in the generator position and under these conditions the charging rate will be from 8 to 9 amp.

Troubled by Excessive Vibration

Editor THE AUTOMOBILE:—I have a 1910 Cadillac. It runs pretty well still, but has a good deal of vibration. Would aluminum or magnalium in pistons reduce this vibration sufficiently to warrant the expense? I am using a Schebler carbureter and getting but 5 miles per gallon. Can you suggest what can be the trouble? I formerly ran about 12 to 14 before installing the new carbureter.

Hibbing, Minn. B. S. A.

—In the opinion of the Cadillac company the effect of substituting aluminum or aluminum alloy for the standard material would not be such as to warrant the expense of same.

Regarding the mileage it would be well to make sure that

the carbureter is correctly adjusted. If in good repair and adjustment, the results obtained should be very satisfactory and the mileage much higher.

Average Output of Ford Magnetos

Editor THE AUTOMOBILE:—What is the average output of the 1914 and the 1915 Ford magnetos in amperes?

2—What is the frequency in cycles per second of each model at 1000 r.p.m.?

3—Am I right in the assumption that the frequency varies with the speed of the motor or is it independent of this?

4—What is the phase of this current?

5—What is the maximum speed at which perfect synchronism may be obtained from a Bosch magneto of the four-cylinder type? I mean by this, the speed of the magneto armature.

Marysville, Ohio. E. C. P.

—The voltage and the amperage of the model T Ford magneto varies according to the speed of the engine. With the ⅝-in. magneto used previous to October, 1914, the amperage ranges from 3 to 5. With the ¾-in. magneto used since that time, the amperage ranges from 5½ to 8.

2—As there are sixteen magnets and sixteen coil spools in the construction of the magneto assembly, it follows that there are sixteen electrical impulses with each revolution of the crankshaft.

3—This is answered under question 2.

4—This is also answered under question 2.

5—Tests made on the Bosch magneto show that it is possible to obtain synchronous ignition from a four-cylinder type at any and all speeds. Tests have been made on instruments where 15,000 sparks were obtained in a minute.

Description of Gearless Differential

Editor THE AUTOMOBILE:—Please give diagram and detail explanation of the gearless differential. Which cars use it?

Detroit, Mich. M. S.

—A diagram of the gearless differential in the form of a sectional view is given in Fig. 1. The actual assembly varies in different cases; that used on the Argo has the housing and the flanges in one piece while in that for the Ford they are in three pieces. The companies using this gearless differential as standard are the Argo Motor Co., Jackson, Mich., and the Woods Mobilette Co., Chicago, Ill., and also various light car concerns which obtain a complete axle from the Detroit Axle Co. The operation of the gearless differential is as follows:

The left hand differential flange, to which differential driving gear is bolted, the right hand flange, the center ring, and the right and left driving sectors, two at top and two at bottom, are all bolted together, making this whole outer differential housing a unit. The right and left ratchets, which are keyed to their respective axle shafts, are independent and free to rotate inside of housing. The two round members with knobs at ends and center, placed crosswise, are the walking beams, or pawls, and are the interlocking mediums between the driving sectors and ratchets. The illustration shows the right hand end of the top pawl in the tooth of the right hand ratchet and being driven by the contact face of the driving sector.

This drives the ratchet forward through the center of the end of the pawl. In the same manner the left ratchet is driven forward by the lower pawl, which is engaged at its left end. Thus both wheels are driven forward positively and neither can spin, as with the gear differential.

To drive backwards, the differential housing starts to move to the left and pushes the end of the pawl out of ratchet tooth, which throws the opposite end of the pawl down into the tooth of the opposite ratchet. Contact face of reverse driving sector engages and drives the wheel backward. The lower pawl acts in the same manner. In turning a corner, imagine that the car is being driven forward and is to be turned to the left. The right wheel starts to revolve faster than the left and causes the right hand ratchet to move faster than the differential housing, which can only go as fast as inner or slower moving wheel. The ratchet pushes the end of pawl out of its tooth, thus allowing the ratchet to have a free movement forward. As soon as the corner has been made and both wheels are revolving at equal speeds, the spring at the center of the pawl pushes the end of the pawl back into engagement and the drive is again taken up by both wheels.

When the wheels propel through the driveshaft, as in case of coasting or braking through it, both ratchets start to turn faster than housing, and push the engaged ends of pawls out of engagement and the opposite ends into driving position in the opposite ratchet teeth, thus causing the ratchets to propel the driveshaft.

Low and High-Tension Magnetos

Editor THE AUTOMOBILE:—What is the difference between a low- and a high-tension magneto?

2—Give a diagram, if possible, of the magneto and battery wiring on the 1907 Packard, using Eisemann magneto.

3—What is the transmission and rear axle gear ratio on the 1910 Briarcliff model Lozier?

4—Describe the oiling system on the 1910 Lozier. Does the oil passing through the sight feed feed to the cylinders or to the crankcase, and about how many drops of oil must the sight feed show?

5—Why does the fourth cylinder smoke on almost all 1910 Loziers?

6—How can a Remy magneto as used on a 1911 planetary Buick be jumped so as to show a spark when disconnected from the motor and regular wiring?

Bronx, N. Y. A. B.

—The difference betwen the low- and high-tension magnetos is that in the low-tension there is only a primary winding where low-tension current is generated, while in the high-tension magneto there is also included a secondary coil in which a high-tension current is induced, due to the interruption of the primary circuit.

2—A diagram of the magneto and battery wiring of the 1907 Packard Eisemann set is given in Fig. 3.

3—The gear ratio of this model is 2.8 to 1.

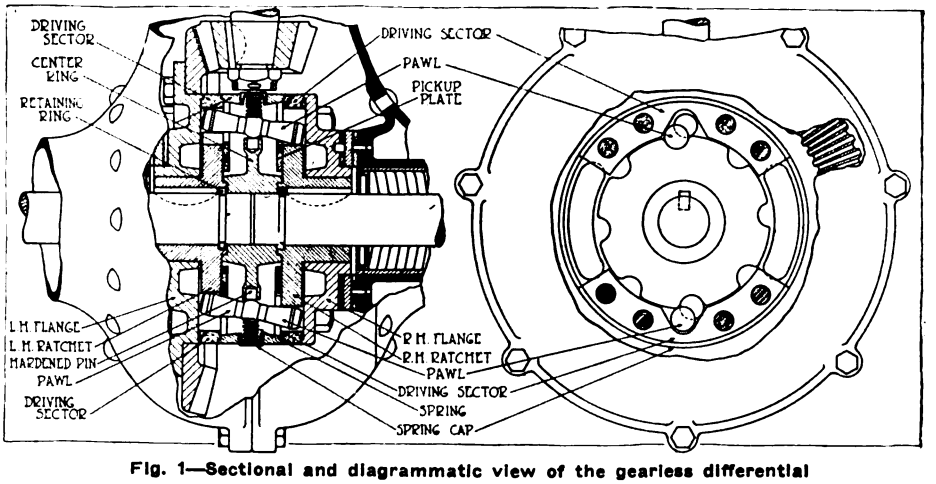


Fig. 1—Sectional and diagrammatic view of the gearless differential

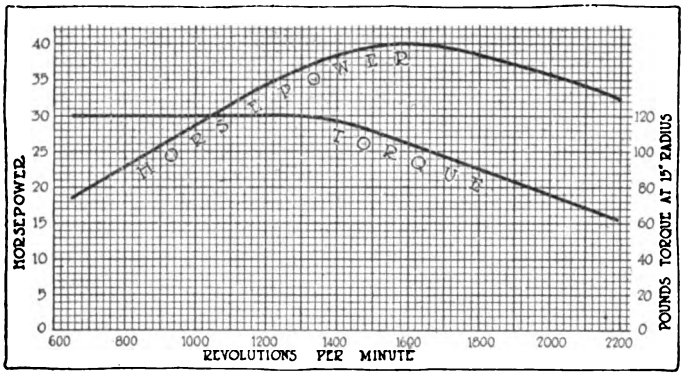

Fig. 2—Horsepower and torque curves of the Continental 4⅛ by 5¼ model C motor

4—The oil is drawn from the auxiliary tank on the side of the engine to the lubricator. It is then distributed by the lubricator to different parts of the motor and direct to the principal bearings. The oil pressure forces the oil back into the lubricator from the sight feed and then indicates that the lubricator is working.

5—So far as THE AUTOMOBILE has record, the statement that the four-cylinder smokes on almost all 1910 Loziers is not strictly correct, although it may be true of a few. If you will press back the tube on the connecting-rod cap to ⅛ in. so that it will not pick up so much oil, it will probably reduce the smoking materially.

6—If you are experimenting with this magneto, it is suggested that you place it in a lathe, using the lathe spindle to drive it, being sure that the magneto is well grounded on the lathe. Also be sure that the spark plugs are grounded to the lathe, that is, the outside of the plugs and not the core.

Wants Parts for Stoddard-Dayton

Editor THE AUTOMOBILE:—Can a set of this year's license plates be transferred from an old to a new car without notifying the license bureau?

2—Who makes the parts for the Stoddard-Dayton car?

3—What motor was used in the 1910, 1911, 1912 and 1913 Hudson?

New York City. J. KING.

—No.

2—Dayton Auto Repair Co., 351 West Fifty-first Street, New York City.

3—Two motors were used in the 1910 Hudson, the Buda and the Atlas. Since then all Hudson engines have been manufactured by the Continental Mfg. Co., Detroit.

Dimensions of Several 1916 Cars

Editor THE AUTOMOBILE:—What is the extreme width and length over all of the following 1916 cars with the top down: Reo four, Reo six, Dodge, Studebaker four and six and Jeffery four?

—The dimensions you request are as follows:

Car	Overall Length	Overall Width
Jeffery four	13 ft. 10 in.	5 ft. 7¾ in.
Studebaker four	13 ft. 8 in.	5 ft. 8 in.
Studebaker six	14 ft. 6 in.	5 ft. 8 in.
Reo four	14 ft. 2½ in.	5 ft. 7 in.
Reo six	15 ft. 6 in.	5 ft. 7 in.
Dodge	13 ft. 0 in.	5 ft. 6 in.

Remedying a Grabbing Clutch

Editor THE AUTOMOBILE:—I have a 1916 Buick model D 45 and find that the clutch grabs very badly. Can you tell me how I can remedy this?

2—I would like to know the price of a Wagner generator which comes on a 1914 Studebaker five-passenger, four-cylinder car. Also, where to look for trouble when it does not generate any electricity?

Troy, N. Y. J. M. S.

—The grabbing clutch is due to insufficient play in the clutch leather expanders which bring the leather out against the inner rim of the flywheel when the clutch is engaged. The difficulty can be easily overcome by removing washers from the ends of expander plunger stems.

2—The price of a new generator is $70. You do not furnish sufficient information to tell you exactly where to look for your trouble, but try the following means of remedying it:

a—Clean generator commutator carefully by using very fine sandpaper (00 grade). Do not use emery cloth.

b—Look for open circuit or loose connections at following points: Generator terminals, back of combination switch and junction box, battery indicator terminals, relay terminals, storage battery terminals.

c—Remove relay cover, start engine, and gently accelerate. If relay contact points close and open automatically as engine is speeded up and down, this indicates that generator is performing properly.

d—Stop engine. Test indicator for reversed connections by switching on headlamp. Indicator should read Discharge. Turn out lights, then start engine, run it at a speed corresponding to about 15 to 20 miles per hour and hold relay contact points closed with the finger. If indicator reads Discharge trouble is in generator. If indicator reads Charging trouble is in relay. If indicator reads Off, trouble is an open circuit.

Horsepower Curve of Continental C

Editor THE AUTOMOBILE:—Please show the power curve of a 4⅛ by 5¼ Studebaker 4-35 model. Also that of a Continental 4⅛ by 5¼ model C four-cylinder motor.

Brooklyn, N. Y. H. E.

—It is against the policy of the Studebaker company to permit the publication of horsepower curves of its motors. The power curve of the model C 4⅛ by 5¼ Continental motor is given in Fig. 2.

Salt Removes Carbon But Rusts Motor

Editor THE AUTOMOBILE:—I have a friend here who drives a Buick and cleans carbon out with salt. He runs his engine 2 or 3 min. to warm up, then removes the spark plugs and puts 1½ normal salt tablets in each cylinder and then runs the car about 15 miles, by which time there is no carbon remaining in engine or valves. I know that this will remove all carbon deposits, but will the chemical action set up by the salt and heat do any damage to the cylinders?

Live Oak, Fla. A. E. W.

—While salt will burn off the carbon by chemical action due to the combination of the salt and carbon into sodium carbonate it is possible that the combination of chlorine with the hydrogen in gasoline would form hydrochloric acid, which would tend to have an intense rusting action on the cylinders.

Lighter Pistons Reduce Vibration

Editor THE AUTOMOBILE:—I have a 1914 Cadillac car and would like to have your opinion as to my making a change on the pistons and connecting-rods. The engine has good power and I think good economy. However, it vibrates a good deal and is not very quiet.

I was thinking that by taking some of the weight off of the pistons and rods that the engine would not vibrate so much and would be more quiet. Also it might increase the power but at the speed I usually run, which is 20 to 25 m.p.h., it might not be noticed. However, if you think it would be a benefit, please tell me what the best method would be in making this change.

Unless the change would be quite an improvement, I hardly think it would warrant my spending very much for it.

Youngstown, Ohio. S. W. G.

—It is probably true that a reduction in the weight of the piston rods in this motor would reduce the vibration somewhat. However, as these pistons and connecting-rods were designed to carry safely only certain loads such as are likely to be imposed upon them, it would be dangerous to weaken them. Practically speaking, it is very much to be doubted if these parts could be made sufficiently lighter than they were originally to reduce the vibration sufficiently to make any perceptible difference.

Cone and Disk Have Even Break

Editor THE AUTOMOBILE:—Please give a discussion of the comparative efficiency of the types of clutches used on modern automobiles—the cone clutch and multiple disk, running in oil and with dry plates. If there is a choice of type of clutch for a particular car, please state which type is the best for which cars. In your opinion, is there an all around best type of clutch?

Brooklyn, N. Y. F. P. BLISS.

—Regarding a general discussion of disk and cone clutches it is very difficult to expound on the advantages and disadvantages of each since they are about equally matched in popularity if the choice of automobile designers in this country can be taken as a criterion. The disk and cone clutches have been hovering on the side of the 50 per cent mark each for the last five years as regards the specifications of American cars. Either type is excellent and will give ample satisfaction.

High Gear Ratio for Buick

Editor THE AUTOMOBILE:—Would there be any advantage in setting the timing gear on the magneto shaft one tooth or two teeth ahead? Would it take up the wear or play caused by two years of running?

What is the gear ratio of the differential in a White Streak Buick? How much higher would you have to gear it to get 10 miles more speed?

Mt. View, Cal. J. C. M.

—The advancing of the magneto gear one or two teeth would not take up back lash caused by wear, but will compensate for lag in the electrical system at high speeds.

The Buick Motor Co. never designated any of its models by the title of White Streak. It is believed, however, that this appellation was applied to some model 10 cars, which were used for racing. These were built with both 3½ to 1 and 3 to 1 rear axles and if you have one in which the gears are marked 48 and 13 you can get more speed by inserting a set of 48 and 15 gears.

Steering Column Is Easily Lowered

Editor THE AUTOMOBILE:—Is there a firm in Missouri manufacturing an automobile signal device for the front and rear of the machine? If so, what is its name and address?

2—Has the Sharon tandem car been used successfully as yet? About how many are in use?

3—Can the steering column of a Studebaker 20 be lowered to any angle without much expense? What must be done to lower it?

4—Does the company which manufactured the Cutting car still exist?

5—Is the silent Knight motor much in demand at the present?

6—What is the horsepower of a Ford?

Seelyville, Ind. L. F.

—It is very possible that the concern which you have in mind is that of A. P. Rothermich, 2915 N. Taylor Avenue, St. Louis, Mo.

2—THE AUTOMOBILE has no record of the performance of these cars.

3—The steering gear on the Studebaker 20 is pivoted to the cross member of the frame, and it can be raised or lowered to certain angles by the installation of a steering post tube and bracket assembly, which can be had by placing your order with the nearest Studebaker dealer. Inasmuch as you do not state the exact angle which you desire, it is impossible to give prices, etc., but the change can be readily made at little expense.

4—No. Parts can be secured from the Puritan Machine Co., Detroit, Mich., or S. C. Erbes, St. Paul, Minn.

5—The Knight motor is being produced in greater quantities this year than ever before.

6—About 20 hp.

Valve Stem Clearance Causes Knock

Editor THE AUTOMOBILE:—Can you tell me what in your opinion would cause a light tap in a Ford motor? This tap is very noticeable at all engine speeds, both when running under load and when idling. It sounds like a too far advanced spark, but this is not the cause. Neither is it caused by the piston striking the cylinder head gasket. The tap is regular and occurs in one cylinder. It is not caused by carbon or connecting-rod trouble.

Washburn, Me. E. M. G.

—From the data you give, it would seem that you are referring to a valve tap which possibly results from worn push rods or valve stems in which case the parts should be replaced and fitted with the proper gap of not more than 1/32 in. and not less than 1/64 in. between the parts. When the gap is too wide between the push rods and valve stems, noise will result.

Knocks which become audible with advanced spark usually originate somewhere in the piston assembly and are probably due to loose pistons, worn piston pin bushings, or to the condition of the bearing at the connecting-rod end. Sometimes it happens that the connecting-rod itself is out of alignment or bent.

Dust Cover Perhaps Too Tight

Editor THE AUTOMOBILE:—Can you help me on this? The high and intermediate gear-shifting fork on my Buick 37 wears out very quickly. I have had to put in three in going 11,000 miles. The machine has been well oiled all of the time. The gears do not cause me any trouble when shifting.

Orono, Me. H. H.

—The cause of the shifter forks wearing on this car is that the control lever binds in its socket. This is caused either by lack of lubrication or else by having the control lever dust cap which fits over the ball socket drawn up too tightly against the side. Make sure the gears mesh fully and do not only half engage.

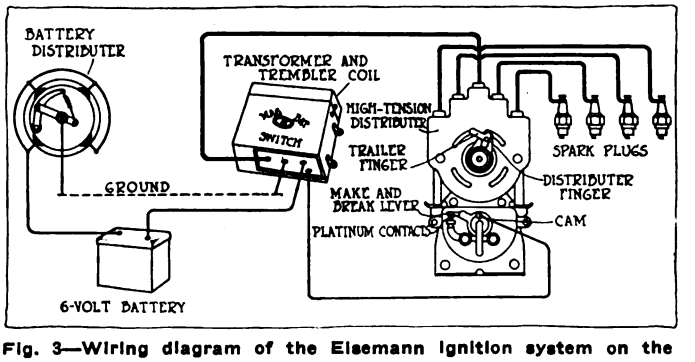

Fig. 3—Wiring diagram of the Eisemann ignition system on the 1907 Packard

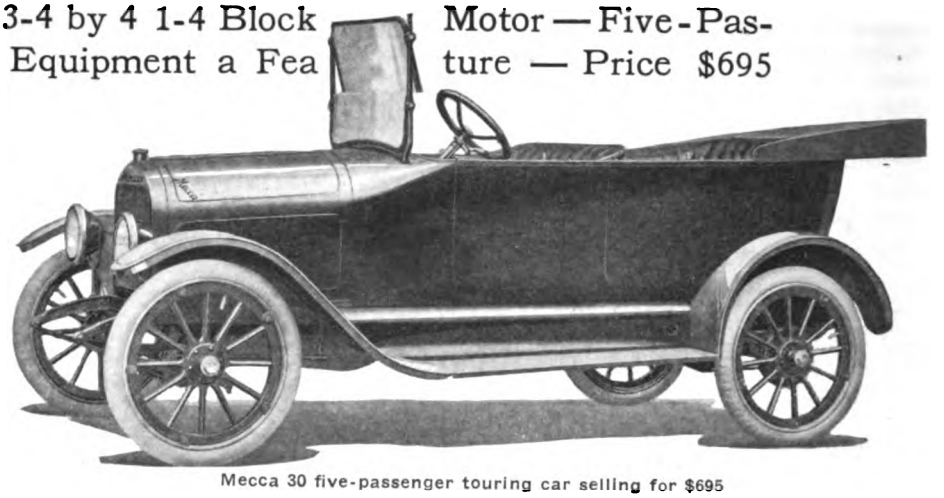
Gearless Differential in Mecca 30

Four-Cylinder 3 3-4 by 4 1-4 Block Motor — Five-Passenger Body — Equipment a Feature — Price $695



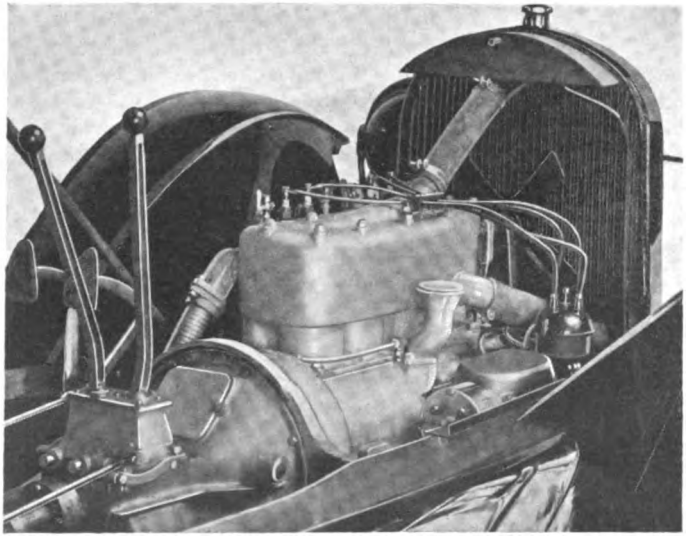
Mecca 30 five-passenger touring car selling for $695

AN assembled car has been put on the market by the Times Square Automobile Co. of New York and Chicago, a concern which has now, in addition to its line of rebuilt and used cars, brought out a product to meet the demands of those desiring a new car at moderate price. The car is made in Detroit and sells for $695 f.o.b. that city.

Standard specifications will be found throughout as the car is assembled from parts made by well-known concerns. The power plant is a four-cylinder Golden, Belknap & Swartz product, having a bore of 3¾ in. with a stroke of 4¼ in. This gives a piston displacement of 187.9 cu. in. This is an L-head design with the cylinders cast in a single block and with a removable top to the cylinders. The motor is of standard construction throughout, the cylinders and pistons being gray iron with light-weight aluminum crankcase and gearset housing bolted together in unit power plant style. The bearings are nickel babbitt and are three in number for the crankshaft. Pounding of the motor at low speeds is guarded against by allowing liberal bearing sizes and a heavy flywheel which keeps the variation in angular velocity at a minimum. The makers claim that with this motor the car is free from vibration up to 40 m.p.h.

Valves Are Large

Cast-iron valves with steel stems are employed. The drive for the valves is through a chain-driven camshaft, thence through the integral cams to positive lifters. The valves have a clear opening of 1⅝ in. in diameter. The outside diameter of the valves is 1 13/16 in. and the lift 7/32 in. The valves are adjustable in the customary manner and are inclosed. The silence features as regards the valve action have been given ample attention as beyond inclosing the valves in removable cover plates the driving chains run in oil and have provision for adjustment to take up any slack.



Unit power plant used in the Mecca 30, showing mounting of the control levers on the top of the gearbox

Ample Factors of Safety

In the selection of materials an ample factor of safety will be found to have been left in all parts under shocking stresses. The connecting-rods are 0.30 to 0.36 carbon steel, drop-forged and heat treated. They are of I-beam section and have ample bearing area both at the oscillating piston pin joint and at the large end bearing on the crankshaft. The bearings in the connecting-rods, as well as those for the crankshaft, are ground to size and the material used in the crankshaft is 0.35 to 0.40 carbon steel. This is, of course, a drop-forging and is heat-treated to produce the rigidity necessary in this class of work.

In the oiling system, which is a pressure feed to the main bearings, the plunger pump is operated directly from the exhaust cam for the number four, or rear cylinder. This pump delivers oil under pressure to a sight feed on the dash whence it passes directly to the motor bearings. In addition to the feed to the bearings the internal parts of the motor are lubricated by the oil mist created by the revolving cranks. This oil vapor pervades the entire crankcase and supplies an ample amount of lubricant to take care of the needs of the pistons and cylinders.

Stewart Vacuum Fuel Feed

A Stewart vacuum system is used for gasoline feed. The carbureter is a Schebler. With this system the gasoline tank, which is of 10-gal. capacity, is hung from the rear of the frame and the auxiliary tank is mounted on the dash. The design of the system is standard and is the same as that employed on a large percentage of American cars this season.

Ignition is by the Splitdorf Dixie model high-tension magneto and the balance of the electric equipment is made up of the Disco units for electric lighting and starting. This is a single unit system connected to the crankshaft by silent chain. The motor generator starts charging the battery at a car speed of about 9 m.p.h. and operates in connection with a Detroit storage battery.

Clutch Runs in Oil

Power is taken from the motor by a single steel drive plate clutch which operates between two wire-woven asbestos friction disks running in oil. The gearset is a selective de-

sign providing three forward speeds. The control is central with the gearshifter lever mounted directly on the cover plate of the gearbox. This clutch and gearbox unit gives a very compact design and one of the features claimed for the clutch is that when once properly set it will never need to be readjusted. According to the maker, with all the parts running in oil to reduce wear and due to the positive action through the series of clamping levers given by the spring pressure, the clutch is never so worn as to need a readjustment. At the time of disengaging the engaging or clamping levers a master ring revolves, positively releasing the disks.

Gearless Differential Used

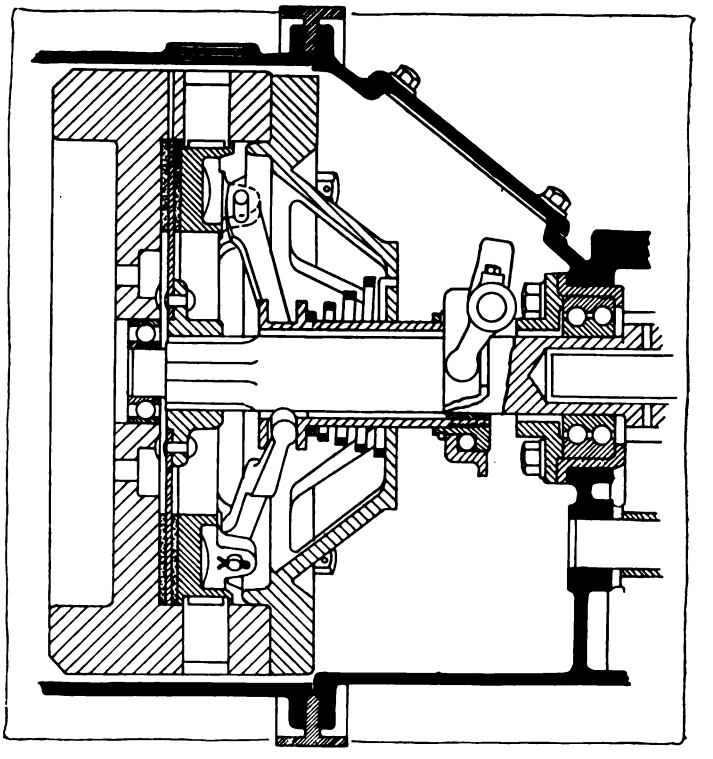
Final drive is through two universals to a semi-floating rear axle. The axle is provided with a gearless differential which is mounted accessibly under a large cover plate. The bearing equipment and the rear axle consist of Hyatt rollers of high-duty type. The frame construction is of pressed channel steel and the springs are semi-elliptic front and three-quarter elliptic rear. The main leaves are of vanadium steel and are guaranteed against breakage for two years. Both sets of brakes are on the rear wheels, the drums are 12 in. in diameter, the wheels are hickory and are equipped with demountable rims taking 30 by 3½ tires. Non-skid tires are furnished in the rear as standard equipment.

3 to 50 Miles per Hour

The chassis length is 104 in. from axle center to axle center and the tread is standard 56 in. providing a road clearance of 10 in. The speed range of the vehicle is from 3 to 50 m.p.h. Steering is by adjustable worm and gear and either left or right drive may be secured as desired.

Five-Passenger Body

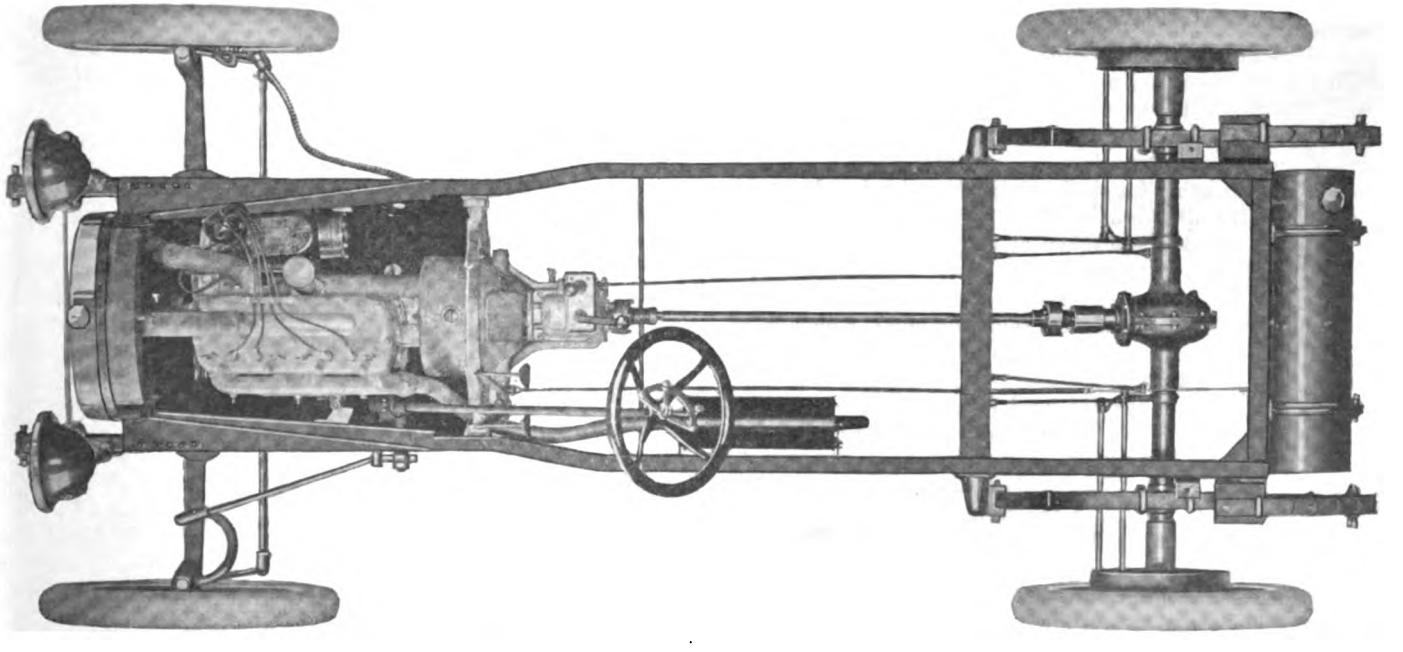
The standard body is a five-passenger touring with streamline design. In addition there is a roadster or raceabout of two-passenger capacity. The cars are finished in what the makers call Mecca blue which is a blue somewhat on the shade of what is commonly known as royal. The car is sold with full equipment including the electric starting and lighting system, two electric headlights equipped with dimmers, electric tail lights, silk mohair one-man top, two-piece rain-vision windshield, number bracket, robe rail, quick-adjustable side curtains, tools, tire holders, extra rim, pump and warning signal.



Section through the clutch used on the Mecca 30 which forms a compact unit with the gearbox. One of the features claimed for this clutch design is that when it is once properly set it will never be necessary to readjust it. All parts run in oil and the action of the spring pressure is positive through the series of clamping levers. At the time of disengaging the clamping levers a master ring revolves, positively releasing the disks.

State Purpose of Sample Invoice

The United Export Bureau of THE AUTOMOBILE has received a report from Jerez de la Frontera, Spain, recommending that where samples are forwarded to prospective customers on memo charge sheets and no actual charge is intended that this should be clearly stated. The report says that recently a merchant in that place was highly indignant on receiving such a memo sheet as he thought he was being charged for the sample. Many such misunderstandings would be avoided by stating the purpose of the invoice.



Plan of Mecca 30 chassis, showing simple but strong construction. This car is assembled from well known units

Use of Optical Indicators for Checking Defects in Functioning of Motors

(*Continued from page 979, last week*)

CONSTRUCTION, adjustment and operation of optical indicators—as practised in Germany—were covered briefly in the first part of this article, which appeared last week. It also gave diagrams illustrating faults related to the admission of gas and to the compression. The closing words referred to Fig. 21 in this issue and faults in the timing of the spark—the subject continued herewith.

Diagrams Showing Faults of Ignition

With only 16 per cent advance, the diagram, *c*, is considerably better, and with 13 per cent advance the best diagram, *f*, is obtained. The correct advance depends of course in each case upon the motor speed and the means used for ignition. A spark that is 5 per cent late gives diagram *e*, and one 10 per cent late diagram *f*. In all these diagrams under Fig. 21 only the changes due to variation in the timing of the spark are shown as they appear. The diagrams in their entirety look somewhat different. The original for diagram *e*, Fig. 21, for example, looks more like Fig. 22. Comparison of the diagram areas under Fig. 21 discloses a serious loss of power efficiency with faulty spark timing. Diagram *e* corresponds to 20 horsepowers and *a* only to 16; *f* to 15. The fuel consumption increases correspondingly with the error in spark adjustment, for any given amount of work to be done.

Misfires are shown in a diagram by an expansion curve almost coinciding with the compression curve, making the diagram look similar to Fig. 17, excepting that the expansion curve lies somewhat above the compression curve because the compression is good and the cylinder wall has imparted some heat to the gas during the compression.

In Figs. 23 and 24, it is plainly shown what influence the position of the spark plug has upon the amount of work done by the motor. With the spark plug over the exhaust valve, one obtains diagrams *a*, *b* and *c* of Fig. 23 at different motor speeds. Diagram *a* represents 640 r.p.m. and shows a maximum pressure of 21.8 atmospheres, while the shape of the diagram remains fairly normal. Raising the speed to 1100 revolutions produces the jagged curve of diagram *b*, and the maximum pressure varies from 14 to 18 atmospheres. If the speed is further increased to 1600 revolutions, the jagged effects in the upper half of the diagram become still more marked and the efficiency lower.

When, on the other hand, the spark plug is placed over the inlet valve, the diagrams of Fig. 24 are obtained. These diagrams, *a*, *b* and *c*, are taken at the same motor speeds as those of Fig. 23, and at the higher speeds there is a notable improvement in the shapes (more easily seen in the original diagrams than in the reduced reproductions) which is explained by the presence of fresh gas mixture in the vicinity of the spark plug terminals.

When two spark plugs are used for one cylinder and they are placed respectively over the exhaust and the inlet valves, the diagrams under Fig. 25 are obtained with the same motor speeds as before. It is seen that in this case the shape of the diagram remains essentially the same at the higher speeds as at the lower, this being due to the more rapid inflammation of the gas mixture when ignited at two places. A simple comparison of the diagram areas—as between *b* and *c* in Figs. 23 and 24 and *b* and *c* of Fig. 25—shows also a considerable increase of the motor power in favor of the double ignition. The incipient jaggedness of the expansion curve of diagram *c*, Fig. 25, shows however that a continued speed as high as 1600 revolutions would not be recommendable for the motor used, the jaggedness indicating a drop in efficiency. These diagrams, as well as some of the following ones, were taken by Professor Watson with a Dalby-Watson indicator.

If a car has both magneto and battery ignition it is easy to compare the merits of the two methods by means of an indicator. Diagrams *a* and *b* in Fig. 26, taken by switching-in respectively the magneto and the coil, in both cases with the gas mixture quite rich, show no important difference in the results obtained from the two methods. But if a poor mixture is used, both maximum and mean pressures during the working strokes are found much more regular with magneto ignition than with coil ignition, the

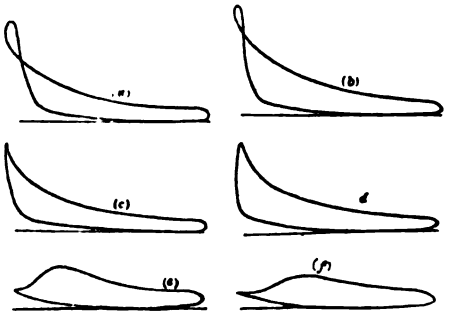


Fig. 21—Faults in spark timing

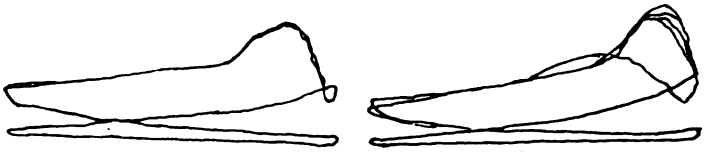

Fig. 22 (left)—Actual diagram of late firing
Fig. 27 (right)—Very poor mixture and late exhaust

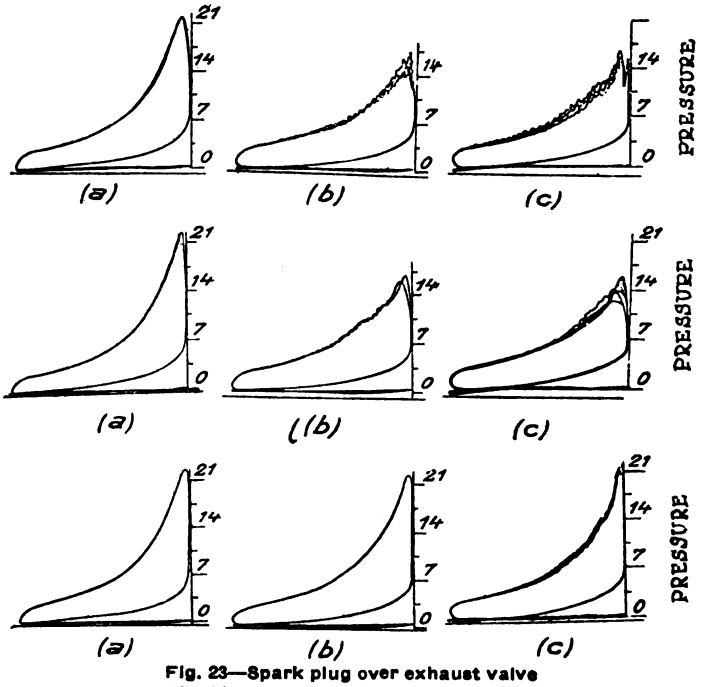

Fig. 23—Spark plug over exhaust valve
Fig. 24—Spark plug over inlet valve
Fig. 25—Spark plugs over both valves
(a) 640 r.p.m. (b) 1100 r.p.m. (c) 1600 r.p.m.

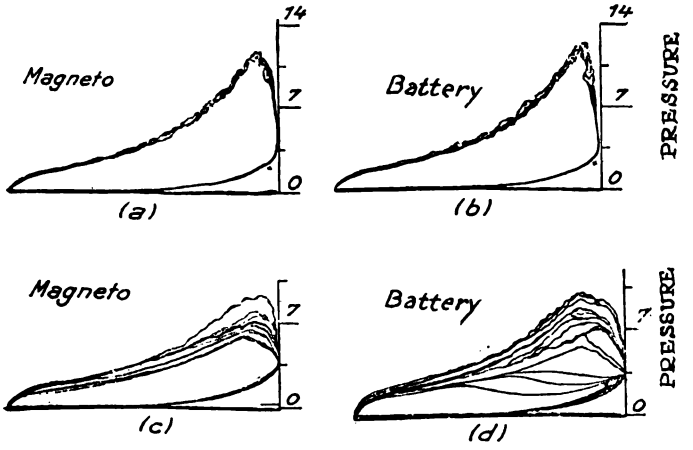

Fig. 26—Comparison of ignition by magneto and by battery and coil—(*a*) and (*b*) with suitable gas mixture; (*c*) and (*d*) with lean mixture

diagrams *c* and *d*, Fig. 26, showing the difference. In some of the cycles, it is noticed, the ignition from the coil progresses so slowly, as in diagram *d*, that the pressure does not reach its highest value till at the end of the work stroke. The small crosses at the compression curves in the diagram of Fig. 26 indicate in each case the point at which the spark was released.

Influence of the Carburetion

That the carburetion, as well as the ignition, has great influence on the power of the explosion and the efficiency of the motor is also demonstrated in detail by means of indicator diagrams. Fig. 27, for example, represents the original diagram of a motor running on a very lean gas mixture. The gas burns with difficulty and has small heating capacity, and the diagram area is therefore greatly reduced. When, on the other hand, the gas throttle is opened completely and the same motor gets a mixture with sufficient gas the diagram of Fig. 28 is obtained. In this diagram it is noticed that the gasoline does not vaporize well or that the carbureter is too cold. Globules of gasoline cause a series of successive small explosions, marked *E* in the diagram, by which the whole volume of the charge becomes subject to vibration. The diagram is a composite of a large number of superimposed photographic diagrams, and the curves are therefore thickened. The first part of the exhaust curve has a strong course, showing that the exhaust valve affords a sufficient opening for driving the gas quickly from *A* toward *B*. By reason of the rapid flow of the gas in the exhaust manifold there arises a slight depression *CD* in the cylinder, lasting through the first part of the suction stroke but disappearing toward the lower dead center *B*.

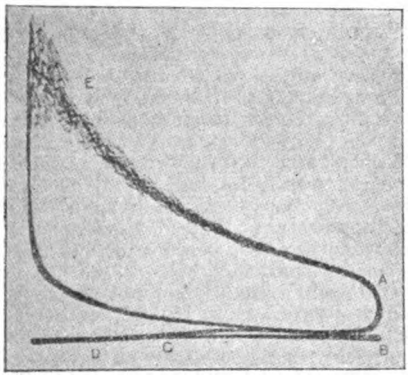

Fig. 28—Composite diagram with gasoline heavy or carbureter cold—Compare Fig. 27

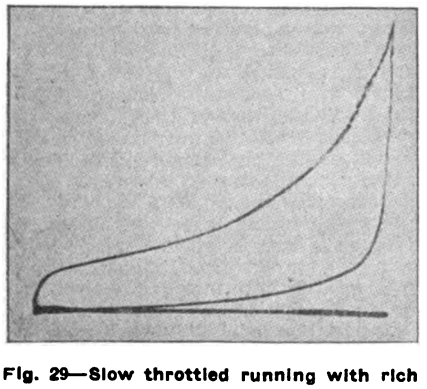

Fig. 29—Slow throttled running with rich mixture

If the same motor is run very slowly but with a rich gas mixture, the diagram of Fig. 29 is obtained, in which the expansion curve is more definite. This effect is due to the necessity of throttling the intake, which favors the vaporization of the gasoline globules, so that the charge is more readily fired. The exhaust begins in this case at the same point as before, but, as the motor runs slowly, atmospheric pressure is reached at dead center *D*. The area is smaller than that of the previous diagram, showing the reduced power of each explosion.

Diagrams of Exhaust and Muffler Action

When the diameter or lift of the exhaust valve is too small or the exhaust pipe is clogged or of too small diameter, the diagram will show an exhaust curve that rises toward the end, such as *ABDC* in Fig. 30, and produces a harmful back-pressure on the piston. The upward arching of the curve at *DE* indicates an extra cause for compression and is due to too-early closing of the exhaust valve. The motor in this instance is also late in opening the exhaust valve, as the expansion curve extends all the way to the dead center before the drop from *A* to *B* begins, while this first part of the exhaust curve should run as *AB* in Fig. 28. Owing to all these defects, the area of the diagram, Fig. 30, is naturally much contracted, indicating reduced motor power.

If the exhaust valve is opened too early, the expansion curve drops suddenly from *A* to *B* as in Fig. 31, and the useful area of the diagram is again reduced.

Indicators may be used to advantage not only to determine the action taking place in the cylinders but also for other organs. By mounting a single indicator on the exhaust pipe, one obtains curves of the exhaust pressure, from which the value of the muffler may be estimated. Figs. 32, 33 and 34 show such exhaust pressure curves for a six-cylinder motor running at 560 r.p.m. Fig. 32 shows the result of using a muffler which gives a rather high back-pressure. The muffler used for Fig. 33 is shown to have been of more suitable design, as here the curve at both ends coincides with the horizontal line representing atmospheric pressure. Fig. 34 represents the curve obtained without using any muffler, and it is noticed that in this case there is a rhythmic succession of pressures and depressions in the exhaust pipe.

The Trade Value of Indicators

As may be judged from the foregoing, most repairmen could learn to use an indicator to advantage for quick diagnosis of motor troubles. Most motors have compression cocks where the indicator may be connected. Its cost is not high. Photographic apparatus may be dispensed with for most purposes, and then a single, rather than a quadruple indicator, will do. The motor need not be dismounted. Improved construction is gradually taking indicators from the laboratory into the trade.

"The Car That Stays Young"

An Incipient Department for Data on Durability

DURABILITY is a homely virtue with small charm. Its light is under a bushel. Its importance is recognized in a general way, of course, but in practice it is a subject for guesswork. The use of alloy steel with anti-fatigue properties is an appreciated feature in construction. Broad plain bearings working under small specific pressures or anti-friction bearings are employed with a view to durability. A reliable lubrication system is understood to be necessary. And the ready exchange of wearing parts is becoming a characteristic of conscientious design. But, apart from these elements in the power plant to which engineers naturally pay close attention, few attempts are made at analyzing the requirements for durability in an automobile or a motor truck into its components, although nearly every portion of an automobile is a working part in the sense of being exposed to severe wear and tear through active and shifting relations to the road, the load, the weather and the traffic. In an article entitled "The Car That Stays Young," which appeared in THE AUTOMOBILE for Sept. 2, 16 and 30, the writer referred to a number of these design features in an automobile which are stationary in relation to the vehicle but become working parts when the vehicle moves over the road, and it was suggested that a great deal might be done for increasing the durability of the automobile as a whole if design and materials for these parts were studied with close consideration for their Durability in its Relation to Cost and Style, in the same manner as durability is studied in the power plant and the transmission mechanism, including the tires.

Real Data Not Obtainable

In the belief that some data on this subject, based on comparative tests, were in the possession of the industry, and that they would interest the automobile-buying public—who without this information drift toward the lowest price consistent with a temporarily attractive appearance—an attempt was made to obtain such data by correspondence with manufacturers' purchasing agents, who are always deliberating questions of quality and price, and from specialty and material makers, but the responses have shown that real data in this large field are either guarded as secrets or have not yet been systematically gathered. Many are willing to admit that their own productions are exceptionally durable and that it would be very desirable to have the public understand that such durability is an excellent reason for high prices. Others are interested in features or materials which look highly promising, being intended to obviate deficiencies in other features or materials so far more generally employed. But nobody seems willing to believe that increased durability often can be attained without increase in the cost of production, solely through a better choice in design or a better knowledge of facts relating to materials. Yet, a durability that costs all it is worth is not so very alluring, and the writer still believes that a great deal of durability goes by default for lack of a SEPARATE study of the subject and SEPARATE publicity for the results of such a study. For the present, however, it seems that the idea of obtaining real data without giving a large amount of time and effort for obtaining them must be abandoned, but there remains the possibility for keeping the study of the subject open on less exacting lines, by means of such contributions as may be received, whether they stick closely to real data or not. In this manner the relation of durability to cost of production and price cannot be brought out sharply, and the ideas on durability will usually be found somewhat interwoven with individual preferences in matters of construction and style or with a too-optimistic faith in promising innovations, but, after all, durability will be kept in the foreground as a subject for inquiry and by degrees will disentangle itself from its complications.

With this modification in tactics, still coupled with the hope that the "stationary working parts" of the automobile may receive their due share of attention, two interesting contributions which show the trend of public opinion, are presented herewith.

An Owner-Driver's Views

Office of The Inspector of Grounds and Buildings — Harvard University

Editor THE AUTOMOBILE:—I have read with much interest the series of articles in your magazine on "The Car That Stays Young." These articles pointed out certain components of the automobile deserving of investigation with a view toward making them more lasting, and indicated the desired results, with suggestions in some cases for their attainment.

One item of the utmost importance which has not yet received attention in this series is that of automatically lubricating all the parts of the chassis now cared for by separate and more or less inaccessible grease-cups, by oil cups and in many cases, such as the springs, by no provision at all.

The average owner who cares for his own car is bound to shirk the filling of grease-cups that are so located as to require a suit of overalls and a subsequent bath for their proper attention. Even when a chauffeur cares for the car, his free time is not always sufficient to give such daily details the best attention.

Owners of medium priced cars who care for them themselves prefer if possible to turn them in each year, rather than be subjected to the annoyance and expense of overhauling made necessary mainly through neglect of lubrication and cleaning. We hear criticisms offered of certain cars, that they are "one year cars," or "10,000 mile cars." This usually means that lubrication is so difficult or badly provided for, that at the end of one year or of 10,000 miles, many parts have worn loose, that the very annoyance of squeaks and rattles drives the owner to turn it in, or else overhaul. These cars have vastly better materials than were used ten years ago. But they wear no better, because dirt and lack of lubricant will wear the best bearing or bushing material made as quickly as the poorest.

If an automobile was so designed that its complete lubrication was a simple, clean and rapid task, and if the lubricated parts were protected from water and dirt, it should be in practically the same running condition after 10,000 miles as after 500.

The present large sales of medium price cars are increasing the number of owner-driven cars in far greater proportion than the number of chauffeur-driven cars. Consequently a development in design which would make it easier for an owner-driver to keep his car at top-notch efficiency, and keep it there a long time, would be an aid rather than a detriment to sales.

Such a car, the "Fergus," has been designed and built in Ireland, and is described in two recent numbers of *The Autocar* of London, England. The editors of that authoritative publication have felt that the production of the "Fergus" is so important that they devoted several pages of editorial to it, as well as a description running in two issues.

I have awaited with interest comment in THE AUTOMOBILE on this car. I hope you are going to say something about it.

Although the design of such a car involves a change in design of many components now standardized, I believe that the time is coming when a car with unlubricated and unprotected springs and steering connections, inaccessible brake parts and a complicated distribution of little, dirty grease-cups in hidden corners; will be as unmarketable as solid bicycle tires.

Cambridge, Mass., Nov. 18, 1915. MAURICE M. OSBORNE.

The subject of convenient lubrication methods as the first and foremost means for making a car stay young has not been overlooked. It was in fact treated by the writer, exactly in this spirit, in an article appearing in *Review of Reviews* in 1906 or 1907. But it was omitted here on account of being complicated by constructional difficulties. It remains to be seen whether these have been overcome in the Fergus car. The builders of this new car have taken the radical and logical step of eliminating watchful waiting from among the duties of the caretaker. Lubricating the car, with their system, is changed from a series of odd jobs to be performed with difficulties and at no particular time—and therefore in practice nearly always after some harm has already been done by neglect—to a filling of reservoirs taking place every six months, for example Jan. 1 and July 1, all the rest being automatic. In the history of American automobiles the Overman steam car furnishes an instance of highly ingenious automaticity, but the automatic features eventually failed unexepectedly by reason of minute cumulative effects in the operation. Some little scepticism may perhaps be entertained as to whether the automatic features in the lubrication of the Fergus car will entirely avoid this danger. The cost of production is another problematic point in this car, since durability can be bought too dearly, especially so long as the ideal of the "one-horse shay" has not been reached in all its components, or finality in its design. Original blueprints of the Fergus car have been secured, however, and readers of THE AUTOMOBILE will be enabled to study its highly interesting construction in a week or two under the expert guidance of Mr. A. Ludlow Clayden.

One Voice from the Industry

The Wayne Works

Editor THE AUTOMOBILE:—We were very glad to note in your circular of the 8th that you are arranging a symposium on the matter of "The Car That Stays Young." It is a point to which more attention should be paid by the public; it is a point to which more attention should be paid by the engineer; it is a point to which more attention should be paid by the heads of motor companies.

The secret of durability is pre-eminently the use of the best material in the right place. Granted, of course, that at least common sense designs are used and that a rational idea of quantity of material is also used. Given two cars of approximately the same weight and power, using approximately the same general dimensions as to parts, the life of the one using inferior material will probably be not over half or two-thirds that of the one using the best material. The use of the very best bearings, the use of alloy steels, the use of testing laboratories, the use of proper heat treating departments, will undoubtedly add to the price of the car. If the American public were willing to pay the difference to gain the car of the best material over the car of mediocre material, the standard of car design and engineering would be very much higher than it is to-day. The fact of the matter is that the public will not pay this price and since the manufacturer has found that his sales are increased by reducing in price either to afford better selling argument for his own car or meet the competition of his rival, to gain this lower price he must inevitably sacrifice quality of material. He, therefore, instructs his engineers to use cheaper bearings, to use cast iron instead of aluminum, to lighten the weight here and there to save stock, to do away with several inserted bushings at various points of wear about the car and probably to continue with an old design modified rather than go to the expense of adopting a new and more modern design. We would all like to make the finest cars that we could, but we can all sell most easily the cheaper car. I use "cheap" in the sense, of course, of not going below a certain standard of engineering and quality of material. A "cheap" car and one that is "cheap" only will not be in the market long, simply because the people will get to know it and it cannot sell at any price. To be sure there have been great economies in factory practice recently. It is much less expensive to manufacture 40,000 crankshafts than 400, but even this does not explain the reason why one car of a certain type, weight and horsepower will sell at $800, while another car of undoubted durability and proved reliability but approximately the same size, weight and horsepower, must sell for $2,500 or $3,000 in order to insure its maker any profit at all. Of course, the American attitude recently has been to buy a car, usually at a reasonable price, use it a year or two and either sell it and buy a new one or trade it in on a new car, not realizing that they must inevitably stand such loss as is also inevitably bound to occur. The buying public properly guided by advance engineering ideas is the final arbiter of automobile design. At present the buying public is decidedly insisting upon low-priced cars. The sort of people who insist on low-priced cars in order to have a car do not get nor expect to get the quality of material and consequent durability and long life of the car that is sold to people to whom first cost is not the prime object and who are accustomed to paying the higher prices in order to obtain the rarer design and the better quality of material. This applies just as well to a suit of clothes as to an automobile. If the buying public insists on buying completely equipped touring cars for $750, touring cars at $750 will be furnished them and the cars will have just exactly $750 worth of value in them and no more. If they want to buy $5,000 cars they will get cars for which, when their durability, comfort, and convenience are considered, the price of $5,000 is not exorbitant, and no rational person can believe for a minute that the $700 car can in any way compete as far as life, comfort and convenience goes, with the $5,000 car. It is most unfortunate that this insistent demand for low priced cars has come about and it is most unfortunate chiefly for the buying public.

Quality of material is, therefore, the first factor to be considered in "the car that stays young." The other point is of course attention and use or, more properly, lack of attention and abuse. A $700 car carefully lubricated, adjusted and handled will give a surprising record as to durability in comparison with a $5,000 car recklessly abused, not lubricated nor attended to in any way.

I hardly agree with the general tone of the third paragraph of your letter for the reason as given above; namely, that reduction of material in either weight or quantity cannot go below a certain point because the natural law of minimum will shortly wipe that car out of existance which does not give at least the service that should reasonably be expected from a car of its list price. In many cases the reduction in the cost of production will result in an increase of durability. For instance, a semi-steel crankcase is probably stronger than an aluminum one. It is at any rate much cheaper but has the disadvantage of increased weight. The modern demand for cars of light weight results in too much material being taken away from the car to a point which, even with the use of modern expensive and durable alloy steels, removes the factor of safety which every car should have. The only way to overcome this disadvantage is to so increase the quantity of production that the economies gained thereby will make up for the additional expense entailed in the use of better material. The reason, to be concrete, why Henry Ford sells so many cars in the course of a year is not the fact that his car sells for $440 which is within the price range of practically anyone, but that it gives even a great deal more service than should reasonably be expected from a car selling at that price. The secret of the efficiency of the car is light weight gained by the use of good material. The secret of the reason that it costs $440 instead of $1440 is that the great economies effected by the quantity production completely absorb the increased expense of better material.

The best way to produce "the car that stays young" is for the man who buys the car to be willing to pay a few hundred dollars more for better material, better design and consequent durability, rather than to pay a few hundred dollars less in order to save money by purchasing a cheaper car; and the only way to gain increased durability by use of high priced material and still keep the car within the range of the purse of the man who does want to buy the car for the few hundred dollars less is by quantity production.

THE WAYNE WORKS.
Per WARREN CLEMENTS,
Wayne, Ind., Oct. 18, 1915. Mgr. Automobile Dept.

The letter by Mr. Clements represents, in the writer's opinion, the general truth in the situation, as between durability and price, but a truth to which the exceptions are so numerous and important that they deserve to be studied especially. It might even be said that it is for the purpose of studying these exceptions—which individual ability and special knowledge never fail to create in order to take distance from the average standard—that a column is kept open for "The Car That Stays Young." With any other view on the subject it would be necessary to assume, it seems, that all cars of the same price are of about the same durability in every feature.—M. C. K.

ACCESSORIES

Traveller Puncture-Proof Tire

WHILE Traveller tires are no heavier than other pneumatic tires of equal quality the manufacturer guarantees them to be puncture-proof and states that they lessen blowout troubles 50 per cent. Of approved construction throughout, these tires have several distinguishing features. The puncture-proof quality is obtained by the use of two unbroken strips of elastic metallic cloth which completely cover the tread, being vulcanized right into the body of the tire. This metallic cloth is said to be ten times stronger than the best quality fabric. As may be seen in the accompanying illustration, the inside of the casing is covered with a water-proof lining which protects the fabric and body of the tire from the effects of moisture, as well as imparting additional strength. Above this are numerous layers of fabric under a thick rubber cushion as indicated. Above this comes the first strip of metallic cloth, which is first chemically treated and then rubberized, being embodied right in the tire structure, so that while it is completely surrounded by rubber it is flexible and resilient. Above this is the first breaker strip and the second cushion, after which comes the second strip of metallic cloth, which is not quite as wide as the first. The extra breaker strip, another cushion and an unusually thick clear rubber tread complete the tire.

Another distinguishing feature, which may be seen in the illustration, is the square formation inside the tread, which not only permits a much thicker tread section but also prevents straining the fabric at any point. It also prevents the bevel which occurs with the ordinary round tire when not fully inflated, resulting in blowouts. The manufacturer states that these tires do not overheat. They are guaranteed puncture-proof up to 5000 miles, a new tire being given in exchange for one defective in this respect. Traveller tires are made in both plain and non-skid treads.—Traveller Tire & Tube Co., Inc., New York City.

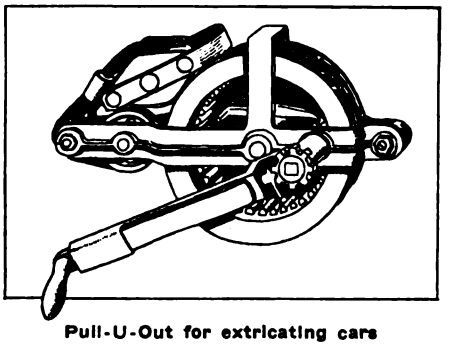
Pull-U-Out for Extricating Cars

A device to help the motorist when his car becomes stuck in the mud or to be used for any of the thousand-and-one circumstances where it is necessary to exert a strong end pull has been brought out under the name of the Pull-U-Out. It is merely a conveniently arranged set of pulleys with a handle for turning so arranged that the total reduction is 70 to 1. The mechanism is quite simple, consisting of a substantial winding drum with gears inside which engage a small bronze gear on the end of a long ratchet crank. Attached to this there are 40 ft. of steel rope with 5000 lb. capacity, and a pulley with two 7-ft. light-weight chains having hooks on each end to complete the pulling device.

The stakes can be readily driven into the ground, but on a straight pull cannot be removed by fifty men pulling with all their might. When the pressure is released and they are pulled up at the correct angle they come out easily. Some of the purposes for which the Pull-U-Out can be employed are, besides removing a car from the mud or sand, lifting a motor from the chassis, towing a car, for a derrick on the rear end of a truck handling heavy baggage, towing a boat through mud, etc The complete outfit sells for $15.—Pull-U-Out Sales Co., St. Louis, Mo.

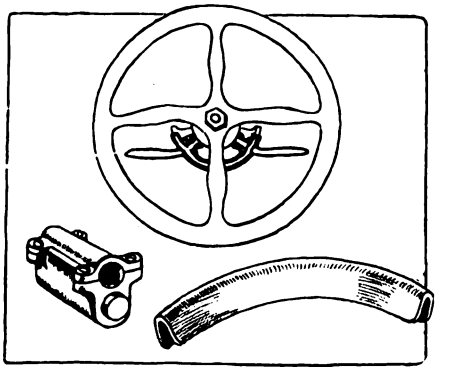


Pull-U-Out for extricating cars

Premo Gas and Spark Sector

The Premo is a neat and easily applied friction sector for the Ford steering wheel to permit a finer regulation of throttle and spark than can be obtained with the original toothed arrangement and also to replace the latter should it be worn.

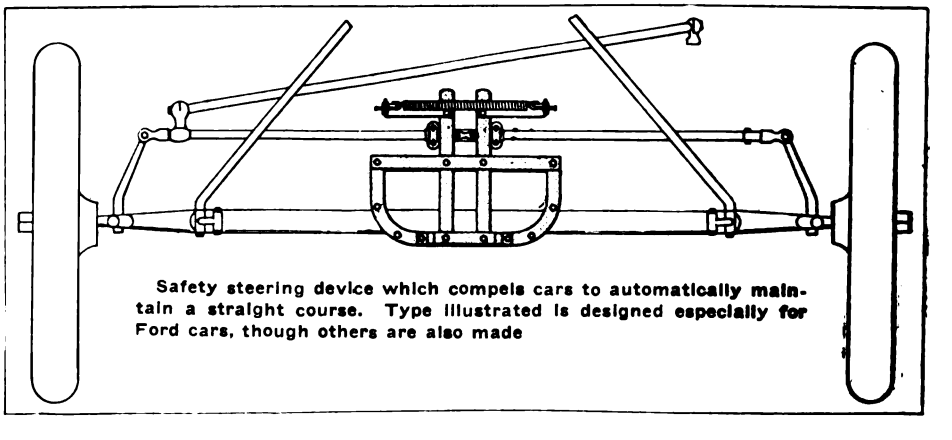
A pressed metal sector slips on over the regular Ford sector and the friction members are attached to the levers, the only tool required being a screwdriver. The device is attractive in appearance and permits the levers to be set at any number of positions. Price, $1.—N. Y. Motor Car Device Co., New York City.



Premo gas and spark sector for Ford cars

Dead Easy Tire Pump

The Dead Easy is a two-stage compression pump operated by a long handle, there being two pairs of cylinders in tandem, each large cylinder having a bore of 3½ in., being surmounted by a small one of 1⅝-in. diameter. A piston rod passing through the dividing head connects the two pistons of each cylinder, the packing in the dividing head acting as a valve in that it allows air to be forced upward from the large cylinder into the small one but prevents its



Safety steering device which compels cars to automatically maintain a straight course. Type illustrated is designed especially for Ford cars, though others are also made

return. A rocker arm is connected with each large piston at the bottom and this is actuated by the handle. The connections are such that the pistons move rapidly at the beginning of the stroke when the pressure is light and slowly toward the end of the stroke when the pressure is greater. Air compressed in the large cylinders is transferred at about 40 lb. to the small ones and thence to the outlet. The pump is 5 by 8½ in. and 9 in. in height and the handle comes in two sections, each 16 in. long. The weight of the device is 13 lb. With cylinders and trimmings nickeled, and other parts black enameled, the pump sells for $15; when the outfit is entirely enameled, $12.50.—Globe Mfg. Co., Battle Creek, Mich.

Safety Steering Devices

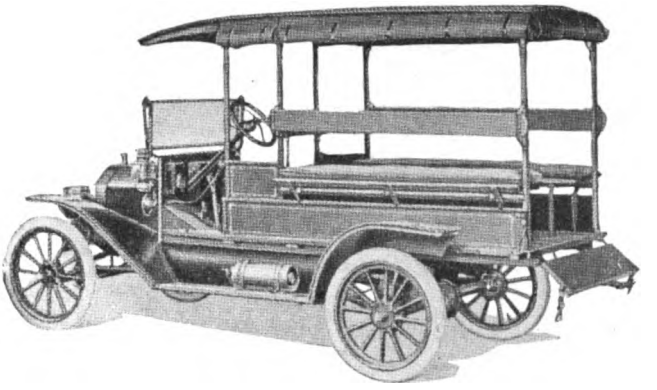
A device to compel cars to automatically maintain a straight course has been devised and is being marketed under the name of the Auto Safety Steering Device. The apparatus is stated to work satisfactorily even when the tie rod has been detached or broken, thereby greatly increasing the safety of the car. A diagram illustrating the principles of the mechanism and its application appears herewith. The device is clamped to the front axle and the cross arm is brought to its central position by a coil spring which acts in either direction. This device is specially designed for Ford cars and can be applied quickly without any machine work.—Safety Steering Device Co., New York City.

Prest-O-Lite Cooking Outfit

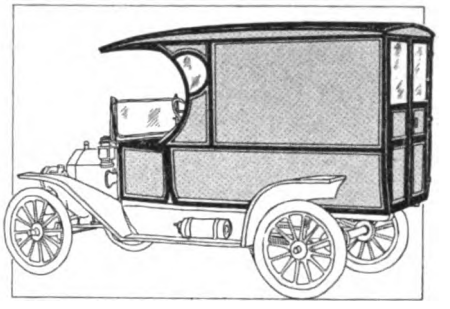
A hot-plate is set on four legs and fitted with a special burner for using acetylene gas from the Prest-O-Lite tank. A rubber tube is slipped over the tank union and the gas turned on and lighted. If the tank is used for lighting on the car the lamp tube is first slipped off. The stove packs into a box measuring 8 by 8 by 5 in. and weighs 6 lb. The makers state that with full flame the gas consumption is 3½ ft. per hour. The full flame will boil a quart of water in 3 min. and is too hot for average cooking. Cost of operation, 8 to 15 cents per hour. The illuminating burner attachment can be used in camp and permits the use of the lighting and cooking feeds separately or together. Tubing is supplied with the stove. Price, stove only, $4.50; stem and illuminating burner, 55 cents; two-way valve for simultaneous cooking and illuminating, 75 cents.—Prest-O-Lite Co., Inc., Indianapolis, Ind.

Henney Bodies for Ford Cars

To meet the demand for an economical delivery car which can be mounted on a chassis of standard design, the Henney bodies have been put out to fit the Ford model T. The complete line comprises seven individual types of bodies: the steel panel in two forms; the general utility with top and flareboards; the general utility with flareboards alone; the steel panel roadster box, which fits behind the regular roadster model; the open flareboard runabout body which also fits behind the roadster driver's seat, and a general utility body with removable side seats and rear steps.

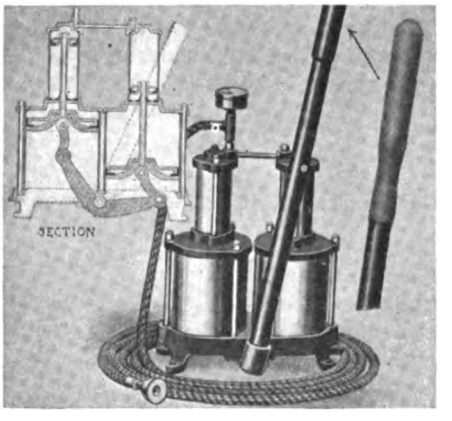


One of Henney Buggy Co.'s open bodies for Ford chassis



A Henney closed type for Fords

This complete line can be varied by different attachments so that all requirements for a light commercial car can be satisfied. The net weight of these bodies varies between 80 lb. and 405 for the steel panel. The prices of the bodies are $99 for the best steel panel, $84 for another model steel panel, $67.50 for a general utility with top and flareboards, $45 for the general utility with flareboards alone, $24 for the steel panel roadster box, $18.75 for the open flareboard runabout body and $90 for the general utility body with removable side seats and rear step.—Henney Buggy Co., Freeport, Ill.



Dead Easy tire pump

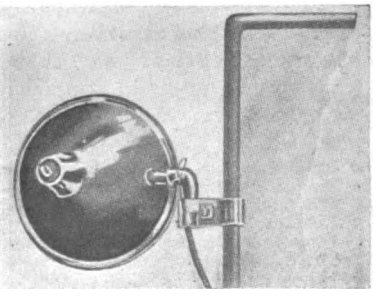
Excelite Spotlight

This convenient spotlight has universal joint provision for mounting on the windshield or dashboard, and is useful for inspecting signs, etc., out of the range of the headlights, while it can also be used to illuminate the motor when repairing or adjusting. A switch and a focus adjustment operated from the outside are located at the back of the lamp. The reflector is 7 in. in diameter. A special type is made for operating on the Ford magneto current and two sizes for truck service, being designed for clamping at the top of the dashboard. The plain type sells for $6 each, while the De Luxe type, with nitrogen bulb and armored cable, is $7. The truck type costs $6 for the 7-in. size and $7.50 for the 9-in.—J. H. Faw, Inc., New York City.

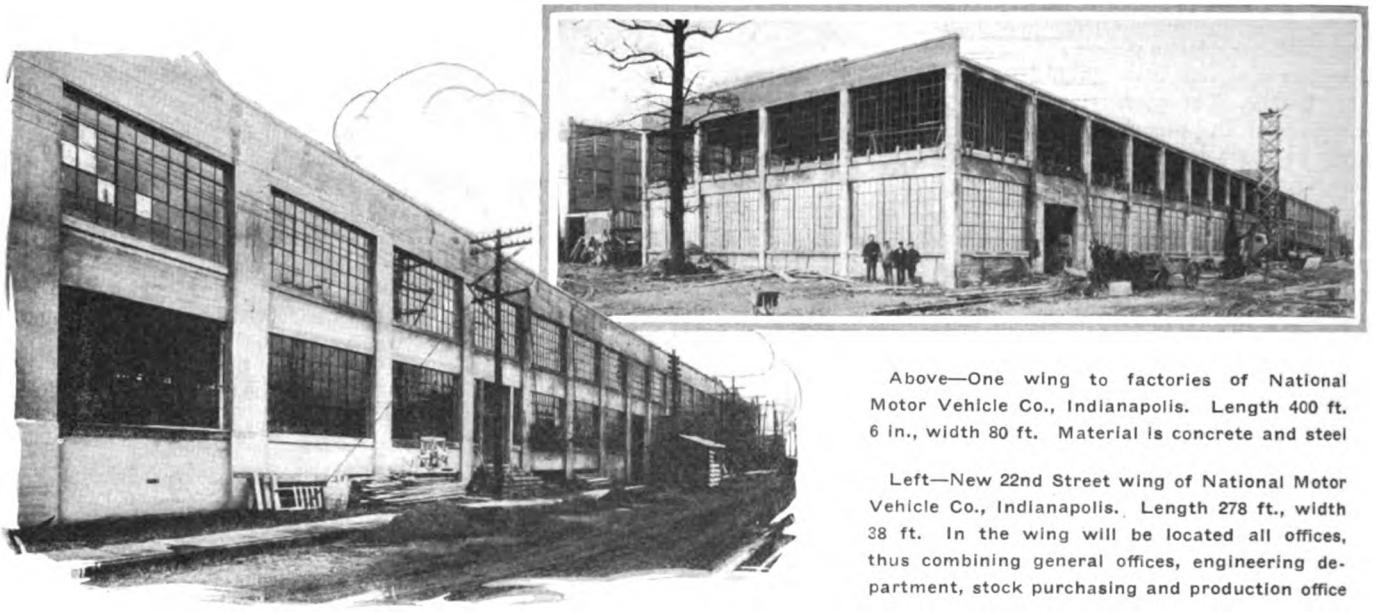
McKinnon Tire Holder

Made in two types, for one and two tires. They attach to running board and fender at right of front seat.—McKinnon Dash Co., Buffalo, N. Y.

Prest-O-Lite cooking and lighting outfit



Excelite swivel lamp on windshield



Above—One wing to factories of National Motor Vehicle Co., Indianapolis. Length 400 ft. 6 in., width 80 ft. Material is concrete and steel

Left—New 22nd Street wing of National Motor Vehicle Co., Indianapolis. Length 278 ft., width 38 ft. In the wing will be located all offices, thus combining general offices, engineering department, stock purchasing and production office

New National Factory Buildings Near Completion

OVER 500 men are working overtime to complete the new factory buildings of the National Motor Vehicle Co., Indianapolis, Ind. The officers of the company hope to be in part of the new buildings in fifteen days and expect to have all of the increased space within thirty days. The new buildings are two stories high and 675 ft. long or approximately two city blocks. One is 38 by 278 ft. and the other 80 by 400 ft. They will cost $100,000. One of the new buildings will include the general offices and in the same building are new quarters for the engineering and production departments.

Geo. M. Dickson, general manager of the company, states that there are three times as many orders on hand than ever before in the fifteen years' existence of the company. He goes on to state that the new buildings will greatly facilitate matters in increasing production to meet the demand and in relieving to great extent the strain on the various departments. They will also reduce the cost of production.
